88. The combination with a bracket or shelf at the front of the machine, and a galley-box detachably mounted on said bracket or shelf and constructed with a longitudinal slot in its bottom wall, of a finger working in the slot of the galley-box, a rock-shaft to which said finger is attached, a tappet-arm secured to the rock-shaft, and a horizontally-sliding mold carrying a device which acts upon the tappet-arm to turn the rock-shaft and swing the vibrating finger, substantially as described.

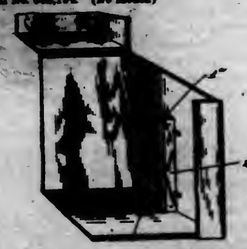
89. The combination with a bracket or shelf arranged at the front of the machine and provided with a leaf-spring attached at one end and having a locking-pin at the opposite end, of a galley-box supported by said bracket or shelf and detachably held thereupon by said locking-pin, a vibrating finger, a rock-shaft to which said finger is attached, a movable mold, and devices for rocking the rock-shaft to vibrate the finger, substantially as described.

90. The combination with the main shaft, having a drive-wheel, a drive-gearing, a clutch between the drive-gearing and the drive-wheel on the main shaft, a clutch-shaft, and a lever for moving the clutch-shaft to operate the clutch, of a spring-actuated dog or pawl pivotally mounted on the drive-wheel of the main shaft and serving to operate the lever to move the clutch and automatically stop the main shaft, and means for subsequently moving said lever to permit the dog or pawl to snap or spring past said lever for restarting the main shaft, substantially as described.

91. The combination with a main shaft having a drive-wheel, a drive-gearing, a clutch, and a clutch-operating lever, of a spring-actuated dog or pawl pivotally mounted on the drive-wheel of the main shaft, substantially as described.

92. The combination of a main shaft having a drive-wheel, drive-gearing, a clutch for connecting the drive-gearing with the drive-wheel of the main shaft, a lever for operating the clutch, means under control of the operator for actuating the clutch-operating lever, and a spring-actuated dog or pawl pivotally mounted on said drive-wheel of the main shaft, to automatically stop the main shaft, substantially as described.

93. The combination with the main shaft having a drive-wheel, a clutch mechanism, and a clutch-operating lever, of a spring-actuated dog or pawl pivotally mounted on the drive-wheel of the main shaft and provided with a projecting beveled finger for automatically operating the clutch-operating lever, substantially as described.

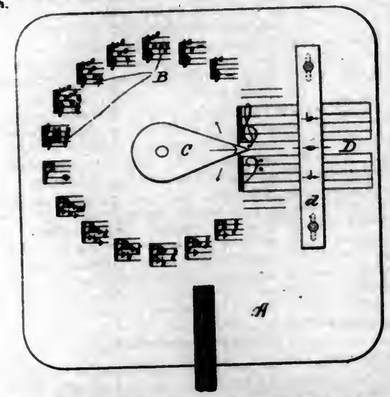


94. The combination with a main shaft having a drive-wheel, driving mechanism having a clutch, a spring-pressed clutch-shaft, a pivoted lever for pressing the clutch-shaft inward, a sliding bar for operating said lever, and means for moving the sliding bar at the will of the operator, of a spring-actuated dog or pawl pivoted on the drive-wheel and having a segmental slot and a beveled finger constructed to automatically operate the lever, and a guide-pin passing through the slot of the dog or pawl into the drive-wheel, substantially as described.

605,142. PIPE-HANGER AND SHIELD FOR BICYCLE-RIDERS. FRANK SKINNER, Philadelphia, Pa. Filed Oct. 13, 1897. Serial No. 655,091. (No model.)

Claim.—In combination a badge, acting as a shield to protect the garment and furnished with means for being attached to said garment, a tobacco-pipe bowl provided with a horizontal annular groove, and a removable, resilient, open, wire loop, said badge and bowl being connected by means of said wire loop, which engages with said groove and by its hooked ends with a slot in said badge, substantially as described.

605,148. TRUNK. PAUL H. SMITH, Columbus, Ohio. Filed Dec. 16, 1897. Serial No. 662,194. (No model.)



Claim.—In a trunk, a device for containing a tray-supporting spindle, consisting of a tubular portion 1 having a notch or opening at its lower edge and a pulley-chamber having walls 2, 2 and connecting-wall 3 communicating with said tubular portion, the said tubular portion having solid prolongations 1ª of said tubular portion 1, substantially as shown and described.

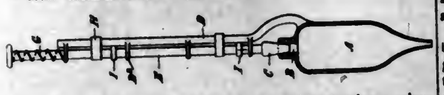
605,144. INSTRUCTING DEVICE. RICHARD SPRINGHORN, Cleveland, Ohio. Filed June 23, 1897. Serial No. 641,533. (No model.)

Claim.—1. In an instructing device, the combination with a plane or sheet having on one face a series of questions and on the opposite face a series of answers corresponding to said questions, of means for coincidently indicating a question and an answer, substantially as set forth.

2. In an instructing device, the combination with a plane or sheet having two faces, said faces so disposed that but one is visible to a beholder at one time, one of said faces provided with a series of questions, the other of said faces provided with a series of answers

corresponding to said questions, of an indicator for coincidently indicating a question and its corresponding answer, substantially as set forth.

3. In an instructing device, the combination with two faces oppositely disposed, one of said faces provided with a series of questions and the other with a series of answers corresponding with said questions, of a double pointer one portion of which is adapted to point to a question on one of said sides and the other portion adapted to point to its corresponding answer on the other side, substantially as set forth.



605,145. SUPPORT FOR ENDS OF RAILWAY-RAILS. JOHN B. SQUIRE, London, England. Filed Dec. 21, 1897. Serial No. 662,808. (No model.)

Claim.—1. In a rail-joint, the combination with the adjoining ends of adjoining rails and the sleepers, of the metal plate having its ends resting upon the sleepers, and the chairs seated upon the ends of said plate and holding the rails above the upper surface of the plate, said plate having a central portion struck up above the main body of the plate and forming a seat for the adjoining ends of the rails, substantially as described.

2. The support consisting of the plate *a*, bent at *f*, *f*, to fit against the beveled inner edges of the sleepers *b*, *b'*, the central part of the plate being curved or arched up sufficiently to support the ends of the rails, the ends of the plate *a* resting upon the opposite sleepers, substantially as set forth.

605,146. PIPETTE. ALFRED W. STORER, London, England, assignor to R. A. Lister & Co., Limited, Dursley, England. Filed Oct. 27, 1897. Serial No. 656,565. (No model.)

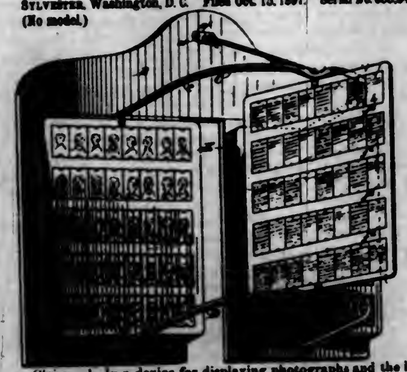
Claim.—1. A pipette consisting of a measuring-chamber, a valve-seat in the upper end thereof, a continuation above the measuring-chamber and a valve and stem guided in said continuation, for the purpose set forth.

2. A pipette consisting of a measuring-chamber, a valve-seat in the upper end thereof, a continuation above the measuring-chamber, a valve and stem guided in said continuation, and means for holding said valve normally open, for the purpose set forth.

3. A pipette consisting of a measuring-chamber provided with a valve-seat in its upper part, and having an upper cylindrical continuation, a valve therefor and a valve-stem guided in the upper end of the said cylindrical continuation, substantially as set forth.

4. A pipette consisting of the measuring-chamber A, with continuation-tube D having openings D' and provided with valve seat B, the valve C with stem E, the latter guided in the upper end of the tube D, and a spring G for holding the valve open, substantially as set forth.

605,147. ROLLER-BEARING. FRANCIS G. SUERBIEL and ADOLPHUS TORREY, Detroit, Mich. Filed Feb. 26, 1898. Serial No. 671,739. (No model.)



Claim.—1. In a roller-bearing comprising upper and lower bearing-plates and a roller-carriage between, a longitudinally-extensible or telescopic coupling-bar pivotally secured at its ends to said upper and lower plates respectively and having an intermediate pivotal connection with said roller-carriage.

2. In a roller-bearing comprising upper and lower bearing-plates and a roller-carriage between, the combination of a transversely-slotted head swiveled to said carriage and a coupling-bar formed in two sections pivotally secured respectively to said upper and lower plates and telescopically engaging with said slotted swiveled head.

3. The combination with the upper and lower bearing-plates, of the roller-carriage between said plates comprising the rolls, a transversely-slotted swiveled head and a carriage-frame formed in two like sections, each having formed therein half-bearings for said rolls and head and adapted when united to hold the same in position and a coupling-bar formed in two sections pivotally secured respectively to said upper and lower plates and telescopically engaging with said slotted head.

4. In a car side bearing the combination with the upper and lower bearing-plates, the latter being secured to the truck, the roller-carriage between, and the coupling-bar uniting the three, of a securing-plate attached to the transom or body portion of the car and vertically, separably engaging said upper bearing-plate.

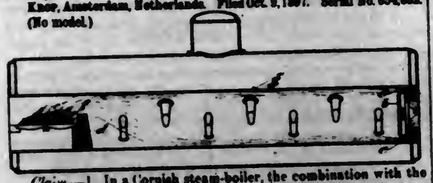
605,148. DEVICE FOR DISPLAYING PICTURES, &c. RICHARD SYLVESTER, Washington, D. C. Filed Oct. 15, 1897. Serial No. 655,342. (No model.)

Claim.—1. In a device for displaying photographs and the like the combination with a frame-support having upper and lower parallel curved guide-rails extending outward therefrom, of frames slidably mounted on said guide-rails, substantially as described.

2. In a device for displaying photographs and the like, the combination with a frame-support having upper and lower parallel curved guide-rails, extending outward therefrom, of frames slidably and rotatably mounted on said guide-rails, substantially as described.

3. In a device for displaying photographs and the like, the combination with a frame-support having upper and lower parallel curved guide-rails extending outward and upward therefrom, of frames slidably mounted on said guide-rails, substantially as described.

4. In a device for displaying photographs and the like, the combination with a frame-support having upper and lower parallel and approximately semicircular guide-rails extending outward therefrom and provided at their outer central portions with recesses, of frames slidably and rotatably mounted on said rails, substantially as described.

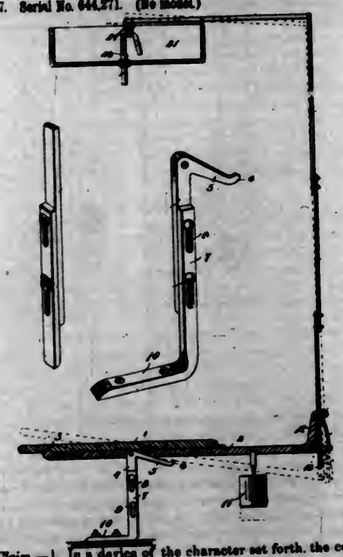


5. In a device for displaying photographs and the like, the combination with a frame-support having upper and lower parallel guide-rails extending outward therefrom and provided on their inner surfaces with guide-grooves, of frames slidably and rotatably mounted on said guide-rails and having centrally of their upper and lower ends headed projections adapted to work in said guide-grooves, substantially as described.

6. In a device for displaying photographs and the like, the combination with a frame-support having upper and lower parallel and approximately semicircular guide-rails extending outward and upward therefrom, and having in their outer central portions recesses and on their inner surfaces guide-grooves, of frames slidably and rotatably mounted on said guide-rails and having headed projections adapted to work in said guide-grooves, substantially as described.

7. In a device for displaying photographs and the like, the combination with a frame-support having upper and lower parallel and approximately semicircular guide-rails extending outward therefrom, of frames slidably mounted on said guide-rails and a cover for locking and protecting all of the frames at one side of the frame-support, substantially as described.

8. The combination with a frame-support having upper and lower parallel guide-rails extending outward therefrom, of frames slidably and rotatably mounted on said rails, comprising side and end frame-pieces, cross-strips extending between said side frame-pieces, apertured clips formed on the end frame-pieces and cross-strips, and means for attaching a photograph to said clips, substantially as described.

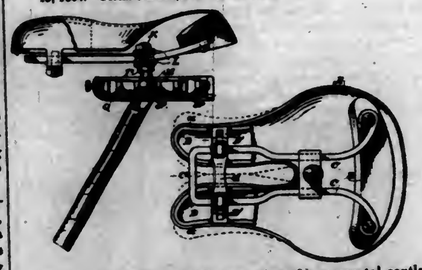


605,149. CORNISH BOILER. HERMANUS THOMASSEN and JACOBUS KROP, Amsterdam, Netherlands. Filed Oct. 9, 1897. Serial No. 654,632. (No model.)

Claim.—1. In a Cornish steam-boiler, the combination with the flame-tube, of the fire-bridge, a sectional disk, wedge-pieces for arranging the same centrally in the flame-tube, a suitable space being left between said disk and said tube, and a ring arranged behind the disk, substantially as set forth.

2. In a Cornish steam-boiler, the combination with the flame-tube, of the fire-bridge, a disk arranged centrally in the flame-tube, an annular space being left between said disk and said tube, and a ring arranged behind the disk the free space over the fire-bridge, the annular space around said disk and the central aperture of said ring being of substantially equal areas, all as set forth.

605,150. SEAT TRIP MECHANISM FOR FLUSHING-TANKS OF WATER-CLOSETS. ELVIN E. TOWNSEND, Captain, Cal. Filed July 12, 1897. Serial No. 644,271. (No model.)



Claim.—1. In a device of the character set forth, the combination of a seat trip-lever, an adjustable fulcrum-support having a stop-arm, a weight attached to said seat trip-lever, a connecting-rod with a slot therein arranged to engage said trip-lever, a spring bearing against said rod, a siphon, and a siphon trip-lever attached to said siphon and adapted to be operated by the said connecting-rod, substantially as described.

2. In a device of the character set forth, the combination of a seat trip-lever to which a seat is attached, a weight connected to said seat trip-lever, a clasp and lug extending rearwardly from the said seat trip-lever, a connecting-rod having a slot therein engaged by the said lug, a spring attached to the said clasp and bearing upon the said connecting-rod, a siphon, and a siphon trip-lever adapted to be operated by the upper end of said connecting-rod, substantially as described.

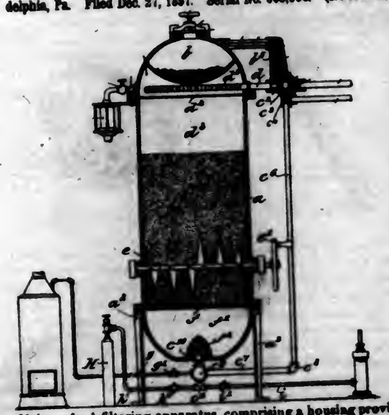
3. In a device of the character set forth, the combination of a seat trip-lever adapted to support a seat and having a rear clasp a lug and an upwardly-projecting extension also provided with a clasp, a weight pivotally connected to said trip-lever, a connecting-rod having a slot therein adapted to be engaged by the said lug, a spring attached to the clasp on the trip-lever and bearing against the said connecting-rod within the clasp on the extension of said lever, a siphon, and a siphon trip-lever connected to said siphon and adapted to be operated by the upper end of said connecting-rod, substantially as described.

605,151. BICYCLE-SADDLE. JOSEPH F. TWIST, San Francisco, Cal., assignor of one-half to Lewis D. Radgesky, same place. Filed Jan. 15, 1897. Serial No. 619,320. (No model.)

Claim.—1. A bicycle-saddle consisting of a segmental cantle, a leather covering, the rear portion of which coincides in shape with the cantle and is fixed thereto, said covering converging from the outer edges of the cantle to the front end, and divided forwardly from the front of the cantle to form independently-adjustable pommels, hollow concave supports for said pommels, having yokes connecting their side edges and slotted transversely, a spring consisting of a continuous piece united at the front end and having arms extending rearwardly from said end and passing through said yokes and united, at their rear, to the cantle, a transverse bar extending from one yoke to the other and bolts passing through the bar and slotted yokes and provided with nuts whereby the pommels may be moved to and from each other and locked, substantially as herein described.

2. A saddle consisting of a continuous rear portion, separated pommels having concavo-convex rigid shaping-pieces fitted into and substantially conforming to the cross-sectional shape of the front ends of the pommels, transversely-slotted yokes joining the free edges of the shaping-pieces at the bottom thereof, a bar extending from one of said yokes to the other having screw-threaded bolts passing through its ends and through the slots in the yokes, a spring consisting of two parallel bars united transversely beneath the front end of the saddle-pommels, extending rearwardly and having its rear ends fixed to the saddle-cantle, yokes through which the bars of the spring pass, formed upon the holding-bolts of the pommel-adjusting device, and adapted to clamp upon the saddle-spring when the nuts are tightened whereby the tension of the saddle may be simultaneously regulated.

3. In a bicycle-saddle, a concavo-convex leather surface with divided front and mechanism for adjusting and fixing the two parts with relation to each other, a spring having essentially parallel bars united at the front extending rearwardly and connected with the cantle of the saddle, means for securing the saddle to the saddle-post consisting of a shank with clamping-bars to grip the spring sides and a holding-nut therefor, a channeled casing formed with or fixed upon the top of the saddle-post, independent blocks slidable therein having concaved ends, a ball formed upon the lower end of the saddle-supporting shank adapted to be fitted between either of the pairs of blocks, and a device whereby the blocks are forced together so as to clamp the ball in position between them.



4. A clamping and adjusting device for bicycle-saddles consisting

of a channeled casing fixed to the upper end of the vertically-adjustable saddle-post in an approximately horizontal position, longitudinally-movable blocks fitting in said casing having the ends made concave, a screw-bolt with means for clamping the saddle upon the upper end, a ball formed upon the lower end adapted to be fitted between either pair of the sliding blocks whereby an adjustment may be made forward or back, and an inclined plane and locking-nuts whereby the blocks are caused to clamp the ball and hold it in any position of adjustment.

5. A clamping and adjusting device for bicycle-saddles consisting of a channeled casing fixed to the upper end of the vertically-adjustable saddle-post in an approximately horizontal position, longitudinally-movable blocks fitting in said casing having the ends made concave, a screw-bolt with means for clamping the saddle upon the upper end, a ball formed upon the lower end adapted to be fitted between either pair of the sliding blocks whereby an adjustment may be made forward or back and an inclined plane and locking-nuts whereby the blocks are caused to clamp the ball and hold it in any position of adjustment, and set-screws passing into the casing to engage and lock the ball after it is clamped in place.

6. In a bicycle, a saddle, a vertically-adjustable saddle-post, a channeled casing at the upper end of the post, longitudinally-movable blocks within the casing and having their ends made concave, a spherical part carried by the saddle and adapted to fit the concave ends of the blocks and means for securing the blocks in position.

605,152. FILTERING APPARATUS. SELDEN TWITCHELL, Philadelphia, Pa. Filed Dec. 27, 1897. Serial No. 663,806. (No model.)

Claim.—1. A filtering apparatus, comprising a housing provided with a coagulant-chamber, a perforated inlet-pipe, a filtering-media chamber having a perforated roof and bottom, a filtered-fluid receptacle beneath said filtering-media chamber, an outlet from said chamber, a valve provided with an operating-lever and a series of ports and connections from said valve with said coagulant and filtering-media chambers and the outlet of the latter chamber, substantially as and for the purposes described.

2. A filtering apparatus provided with a valve having a series of ports and an operating-lever, said valve adapted to be connected with the supply and discharge from the apparatus, sterilizing, carbonating and aerating appliances connected with the apparatus and outlet for the filtered fluid, substantially as and for the purposes described.

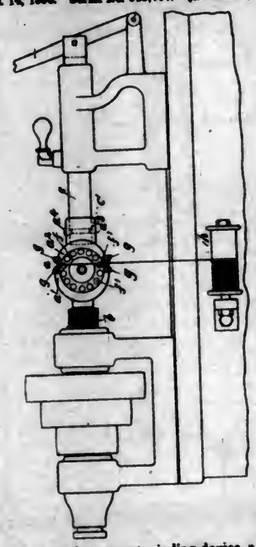
3. A filtering apparatus, comprising a housing provided with a coagulant-chamber having a removable clamp-plate, a perforated pipe located beneath said chamber, a filtering-media chamber provided with a removable perforated roof and bottom, a filtered-fluid-receiving chamber located beneath the same, and a valve with internal ports and an operating-lever connected with said chambers and with the fluid-supply and filtered-fluid discharge of said receiving-chamber, substantially as and for the purposes described.

4. A filtering apparatus, comprising a housing provided with a coagulant chamber, means for presenting a fluid to a filtering media through a chamber provided with a perforated roof and bottom, a filtered fluid or water receiving chamber provided with a rose, and a combined inlet and outlet therefrom, a valve provided with a series of ports leading by pipe connections to and connected with said apparatus, and means for carbonating, sterilizing or aerating said filtering media, substantially as and for the purposes described.

5. A filtering apparatus, comprising a housing provided with a coagulant-chamber, a valve provided with ports and an operating-lever and said coagulant-chamber connected with said valve-casting and with the supply for the fluid to a filtering-media chamber having a perforated roof and bottom, a rotatable agitating device mounted therein, a filtered-water-receiving chamber located beneath said filtering-media chamber having an outlet to and from said valve-casting, and a waste-outlet above said filtering-media chamber provided with a stop-cock and sight-gage, substantially as and for the purposes described.

605,153. SUSPENSION-BRIDGE. JOHN A. L. WADDELL and IRA G. HENDRICK, Kansas City, Mo. Filed Oct. 14, 1897. Serial No. 655,138. (No model.)

Claim.—1. In a suspension-bridge, the combination of one or more towers, pivoted at their lower ends so as to tilt lengthwise of the bridge, with cables connecting the upper ends, and cables connecting the lower ends of the towers, and suspenders holding the upper and lower cables in inverted curves as to each other, as shown.



2. In a suspension-bridge, the combination of one or more towers, pivoted at their lower ends so as to tilt lengthwise of the bridge, cables connecting the upper ends and cables connecting the lower ends of the towers, and suspenders holding the upper and lower cables in inverted curves as to each other, with weights at the lower connection of the cables, to take up the slack and distribute the load over the whole bridge, substantially as shown.

3. In a suspension-bridge of the construction substantially as set forth, the rockers *g g*, the weights *w w*, the beam *h*, and the guides *i*.

4. In a suspension-bridge having lower cables, a connection between spans, which is above the bearing of a pivoted anchorage, so as to permit an adjustment of those cables lengthwise of the bridge, substantially as shown.

5. The combination of the lower cables *b b*, the rocker-beats *d d*, the small rockers *g g*, and the automatic adjustment composed of the weights *w w*, the beam *h*, and the guides *i i*, in a suspension-bridge as herein described.

605,154. INSTRUMENT-WINDING DEVICE. HENRY H. WAIT, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Dec. 14, 1896. Serial No. 615,707. (No model.)

Claim.—1. In an instrument-winding device, a chuck formed in two parts or sections which are adapted to engage a core, each of said parts being provided with a lip, said lips being oppositely placed, the opposing surfaces of the lips diverging outwardly from the core-receiving surfaces of the chuck, substantially as described.

2. The combination of a chuck formed in two parts or sections which are adapted to engage a core, with two diametrically opposite lips provided upon each section, the lips upon one section being opposed to the lips upon the other section, while the opposing surfaces of said lips diverge outwardly from the core-receiving surfaces of the chuck, substantially as and for the purpose set forth.

3. The combination of a chuck formed in two parts or sections which are adapted to engage a core, with two diametrically opposite lips provided upon each section, the ends whereof are rounded, the lips upon one section being opposed to the lips upon the other section while the opposing surfaces of said lips diverge outwardly from the core-receiving surfaces of the chuck, substantially as and for the purposes specified.

4. In an instrument-winding device, a chuck formed in two parts which may be closed together to secure a core between them and separated to remove said core, the members of said chuck being provided with opposing lips constructed to direct wire upon said core, substantially as described.

5. In an instrument-winding device, the combination with a chuck, of means for causing the rotation thereof with relation to the material that is to be wound upon the core in a plane substantially parallel with the plane of the winding, and diametrically-opposed lips provided upon said chuck at the places where the material is to be wound upon the core, said lips being constructed to direct the material upon the core as the core is relatively rotated, substantially as described.

605,155. VELOCIPEDE. JOHN I. WARMAN, Chicago, Ill. Filed Oct. 26, 1896. Serial No. 610,283. (No model.)

Claim.—1. In a velocipede, the combination of two parallel, laterally opposite, upright frames and rear driving-wheels mounted therein a saddle above each of said wheels, pedal mechanism for driving each wheel independently of the other, horizontal transversely-arranged supporting-bars extending between and rigidly connecting said upright frames at points between the driving-wheels and at their front ends respectively, a steering-truck connected with the central part of the foremost one of said transverse members, steering-wheels connected with said steering-truck at each side thereof, steering-handles in front of each saddle and interconnecting means between said handles and the steering-wheels whereby the latter may be turned by either rider, the arrangement of the transverse supporting-bars, and the steering-truck being such that an open space is provided between the pairs of wheels adapted to receive a stretcher arranged horizontally at full length with the head and foot ends of the same projecting beyond the axes of the front and rear pairs of wheels respectively.

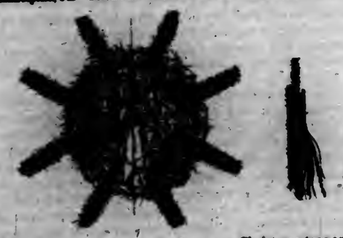
2. In a velocipede, the combination of two parallel, laterally opposite, upright frames and rear driving-wheels mounted therein a saddle above each of said wheels, pedal mechanism for driving each wheel independently of the other, horizontal transversely-arranged supporting-bars extending between and rigidly connecting said upright frames at points between the driving-wheels and at their front ends respectively, a steering-truck connected with the central part of the foremost one of said transverse members, vertically-arranged steering-wheel spindles revolubly mounted one at each side of said steering-truck, steering-wheels mounted upon said spindles so as to oscillate about the latter, steering-handles in front of each saddle and interconnecting means between said handle and the steering-wheel whereby the latter may be turned by either rider, the arrangement of the transverse supporting-bars and steering-truck being such that an open space is provided between the pairs of wheels adapted to receive a stretcher arranged horizontally to rest at full length upon said members with the head and foot ends of the same projecting beyond the axes of the front and rear ends of wheels respectively.

3. A carrier-velocipede comprising two laterally-supported transversely opposite upright driver-supporting frames, each embracing wheel-forks, steering-spindle, handle-bars and pedals, a driving-wheel mounted in the forks of each upright supporting-frame and driving connections between the pedals thereof and said driving-wheel, a horizontal supporting-frame suspended between said upright frames and supported at its front by means of a pair of transversely opposite steering-wheels arranged to oscillate upon separate vertically-arranged steering-spindles located at each side of and in rear of the front end of the horizontal frame and interconnections between the individual steering mechanism of the upright frame and said steering-spindles whereby the steering-wheels are caused to move in unison.

4. The combination of the upright frames A A', provided with the driving-wheels and driving mechanism, the transverse rear and front frame members B B², respectively, the truck-frame member B³ rigidly connected with the transverse frame member B²; the vertical oscillatory spindles B⁵ connected with the opposite sides of said truck-frame member and the interconnected steering mechanism, whereby the vehicle may be steered by either driver, substantially as described.

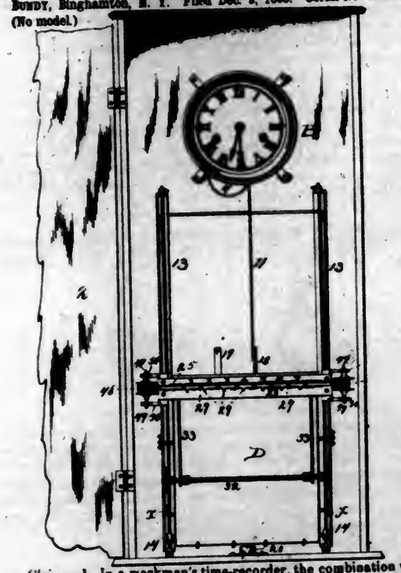
605,156. COUPLING FOR PNEUMATIC TIRES. FRANK WARNOCK, Elyria, Ohio. Filed Feb. 3, 1897. Serial No. 621,822. (No model.)

Claim.—The herein-described coupling for the purposes set forth, comprising a casing having a tapering opening and a longitudinally-bored stem, a pin rotatably mounted in the tapering opening and having its end portions exterior to the casing and its intermediate portion of a corresponding taper to snugly fit the tapering opening, exteriorly grooved, and formed with a transverse opening, and having a projecting end portion exteriorly threaded and longitudinally bored, and a nut mounted upon the threaded end portion to hold the pin in place and provide for taking up wear, substantially as set forth.



605,157. VOCAL AND INSTRUMENTAL NOTE-READING DEVICE. ROSS G. WINKELMAN, Grover Hill, Ohio. Filed May 17, 1897. Serial No. 637,013. (No model.)

Claim.—1. The combination with a musical chart having perforated notes as a musical staff through which notes may be read of a slide or card beneath provided with characters indicating the names of notes, fingering, or chords, substantially as set forth.



2. The combination, in a musical chart, of the slide *i*, having the different signatures in sharps and flats and their corresponding scales and lettering of the instrument; with the face-card A, having scales with perforated notes, through which the various scales may be viewed, substantially as described, and for the purpose specified.

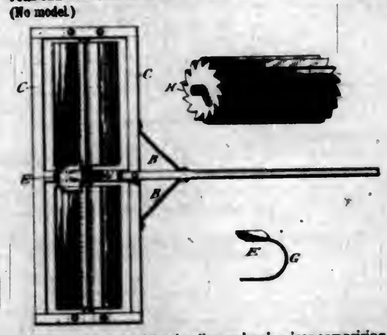
605,158. CHRISTMAS-TREE ORNAMENT. BERNHARD WILMSEN, Philadelphia, Pa. Filed June 18, 1897. Serial No. 641,310. (No model.)

Claim.—As an article of manufacture, a Christmas-tree ornament consisting of a foundation, a supporting-block therefor to which it is secured and beyond which it extends, garlands secured to the inner face of said foundation and extending radially beyond the same, a facing ornament attached to said block opposite said foundation, and a backing ornament secured on said foundation.

605,159. WORKMAN'S TIME-RECORDER. WILLARD LE GRAND BUNDY, Binghamton, N. Y. Filed Dec. 9, 1895. Serial No. 571,455. (No model.)

Claim.—1. In a workman's time-recorder, the combination with a case, a horizontal bar across it provided with a multiple series of separate keyholes, a clock mechanism, a flat record-sheet suspended therefrom and raised by it, an ink-ribbon in the plane of said keyholes and in front of said sheet, of an impression-frame consisting of a rock-shaft transverse to said case, arms thereon, an impression-platen upon said arms, in rear of said record-sheet, and common to all of said keyholes whereby it is actuated to strike an impression-blow by the insertion of a workman's designating-key into any keyhole and print the numeral of the key onto that part of the moving record-strip, which is opposite the keyhole used.

2. In a workman's time-recorder, a record-sheet and a rectangular frame having a series of spring-hooks upon its cross-bars whereby said sheet is mounted upon said frame and held taut, flat and smooth by the spring tension of said hooks in combination with a suitable drum to which said frame is connected and means to rotate said drum and thereby raise said frame and sheet.



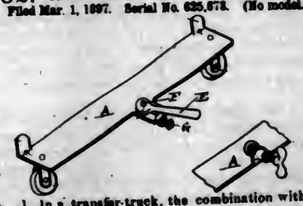
3. In a workman's time-recorder, a vertically-movable frame, a record-sheet removably mounted thereon, a clock-movement, a drum rotated thereby, a cord connecting said drum to said frame, and means to trip said drum at a predetermined time and permit said frame to return to its starting-point, in combination with a vibratory platen of a length equal to the width of the sheet, actuated by the manual thrust of a key inserted into a keyhole in alinement with said platen to strike a blow upon and print the workman's designating-numeral of said key onto said sheet.

4. In a workman's time-recorder, a flat record-sheet vertically movable, and parallel bars and connecting-partitions creating a series of keyholes extending the entire width of the sheet, in combination with a bell-hammer actuated to strike a blow by the insertion of a key into any one of said keyholes, and a bell normally out of the path of said hammer and mounted upon a swinging frame by which it is brought into position to receive the hammer-blow, by the insertion of said key.

5. In a workman's time-recorder, the combination with a rock-shaft having crank-arms upon its ends and an impression-platen mounted upon said shaft, of a parallel rock-shaft, bell-cranks upon its ends, the rearward arms of which are suitably connected to said crank-arms and having their vertical arms connected by a key-bar parallel with the face of the platen, whereby when a key is inserted into a keyhole it swings said key-bar and platen in parallelism.

6. In a workman's time-recorder, a flat record-sheet, an ink-ribbon transverse thereto, a horizontal key bar across the front of said sheet and ribbon and parallel therewith, combined with an impression-platen across the rear of said sheet and ribbon, and parallel with them and with said key-bar, and means to connect said key-bar, and platen whereby the insertion of a key into a keyhole will actuate said key-bar to vibrate said platen to strike an impression-blow against said sheet to imprint the numeral of the inserted key upon said sheet.

605,160. COMBINED DIRT ROLLER AND PULVERIZER. LAFFORD CHAMBERS, Bartlett, Iowa. Filed May 23, 1896. Serial No. 592,893. (No model.)



Claim.—A combined land roller and pulverizer comprising a cylindrical body or bodies, the surface of which is fluted, thereby forming longitudinal crushing blades or bars arranged tangentially mounted in a suitable supporting-frame provided with a draft device whereby when the roller is drawn in one direction the soil is cut and pulverized, and in the reverse direction the soil is smoothed, substantially as described.

605,161. NIPPLE FOR NURSING-BOTTLES. ARCHIE CLEMENT and WILLIAM R. WILKINSON, Chicago, Ill. Filed May 22, 1897. Serial No. 637,774. (No model.)

Claim.—A rubber nipple having a flange *d* at the base, and three ribs placed on the interior walls, extending from the orifice to the neck of the nipple, each rib recessed at C, the point of contact with the gums of the infant, as and for the purpose specified.

605,162. TRANSFER-TRUCK. HERBERT C. DEANE, Fitchburg, Mass. Filed Mar. 1, 1897. Serial No. 625,678. (No model.)

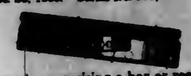
Claim.—1. In a transfer-truck, the combination with the body of the same, of ears or lugs formed upon one side thereof, an adjustable pintle upon the other side, and a cam swiveled upon said pintle to clamp the truck to the article desired.

2. In a transfer-truck, the combination with the body portion thereof, of ears or lugs formed upon one side of the same, an extension upon the other side formed with a longitudinal slot, a bolt having a pintle passing through said slot, a screw passing through a hole tapped through the end of said extension and engaging said bolt to adjust the pintle in the slot, a cam swiveled upon said pintle, and a lever to operate the cam.

605,163. ERASER. BYRON R. GOLDSMITH, New York, N. Y. Filed May 16, 1895. Serial No. 549,763. (No model.)

Claim.—1. A pencil or ink eraser composed of a holder having a tapering, contracted nozzle and a block of erasing material with a body portion of such size as to pass freely through the mouth of the nozzle, and a head or enlargement conforming in shape to the tapered nozzle and too large to pass through the mouth thereof, substantially as described.

2. A pencil or ink eraser composed of a holder having a contracted nozzle and an inwardly-projecting ledge behind the same, and a block of erasing material having a body portion of such size as to pass freely through the mouth of the nozzle and formed with a head conforming to the nozzle and too large to pass through the mouth thereof, and engaging the ledge, substantially as described.



3. A pencil or ink eraser composed of a holder consisting of two pieces of such shape that, when secured together, they conspire to form a contracted nozzle, and a block of erasing material formed with a body portion free to pass through the nozzle and a head or enlargement conforming to the nozzle too large to pass through the mouth thereof, substantially as described.

4. A pencil or ink eraser composed of a holder consisting of two pieces of such shape that, when placed together, they conspire to form a number of contracted nozzles, and blocks of erasing material, one for each nozzle, each block being formed with a body portion of such size as to freely pass through the nozzle and a head or enlargement conforming to the nozzle and too large to pass through the mouth thereof, substantially as described.

5. A pencil or ink eraser, composed of a holder consisting of two pieces of such shape that, when placed together, they conspire to form a number of contracted nozzles each with an inwardly-projecting ledge behind it, and blocks of erasing material, one for each nozzle, each block being formed with a body portion of such size as to freely pass through the nozzle and a head or enlargement conforming to the nozzle, too large to pass through the mouth thereof, and engaging the ledge, substantially as described.

6. A pencil or ink eraser composed of a holder having a contracted nozzle, a block of erasive material having a body portion of such size as to pass freely through the mouth of the nozzle and a head conforming to the nozzle and too large to pass through the mouth thereof, and means for preventing rearward movement of the erasive block in the nozzle, substantially as described.

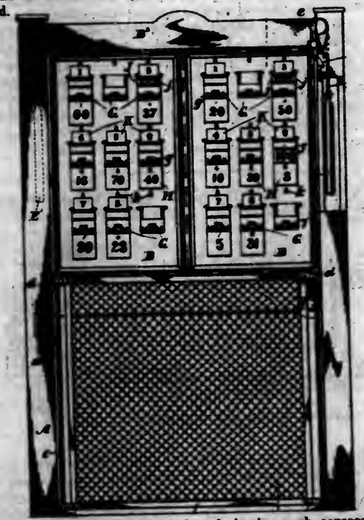
605,164. GAME OR PUZZLE. BYRON R. GOLDSMITH, New York, N. Y. Filed Sept. 26, 1895. Serial No. 563,968. (No model.)

Claim.—1. A puzzle, comprising a box or receptacle, a cage universally supported within the receptacle, and one or more easily-movable bodies also within the receptacle, substantially as described.

2. A puzzle, comprising a box or receptacle with a transparent cover, a cage universally supported within the receptacle, and one or more easily-movable bodies also within the receptacle, substantially as described.

3. A puzzle, comprising a box or receptacle, a universally-hung cage within the same, provided with seats in its periphery, and one or more movable bodies also within the receptacle, substantially as described.

4. A puzzle, comprising a box or receptacle with a transparent cover, a cage universally supported within the same and having seats in its periphery, and spherical or other easily-movable bodies within the box, substantially as described.

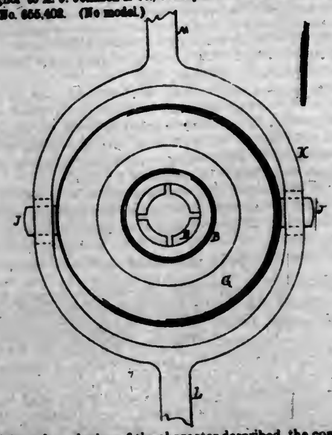


5. A puzzle, comprising a box or receptacle, containing a cage supported in a manner to be capable of universal movement in all vertical planes passing through the point of support, and one or more spherical or other easily-movable bodies of greater height than the mean distance of the edge of the cage from the bottom of the box, substantially as described.

6. A puzzle, comprising a box or receptacle containing a cage, loosely supported upon a pin at a point above its center of gravity, and a number of spherical or other easily-movable bodies of greater height than the mean distance of the edge of the cage from the bottom of the box, substantially as described.

7. A puzzle comprising a box or receptacle, a cage, supported within the receptacle, free to swing in vertical planes and to rotate in a horizontal plane and one or more easily-movable bodies also within the receptacle, substantially as described.

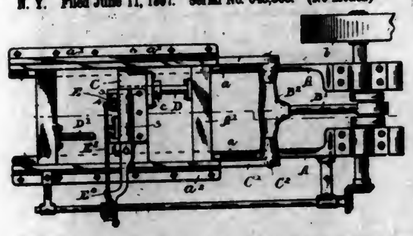
605,165. TICKET RACK AND REGISTER. EDWARD C. HOPPER, Covington, Ky., and CHARLES P. McLEAN, Cincinnati, Ohio. Filed June 30, 1897. Serial No. 643,870. (No model.)



Claim.—1. In a ticket and registering rack the combination of the board, the ticket-clips secured thereon, the name-plate holders above each clip, and the hinged shutters having numerals to indicate the number of the clip when thrown up and closed over the plate when no tickets are held by the clip, substantially as shown and described.

2. The combination of the boards having each consecutively-numbered ticket-clips secured thereon, the swinging member of the clip having a leg projecting therefrom to open the clip and form a hook to suspend the last ticket and block when a new block of tickets is to be inserted, the name-plate holders above said clips, and the hinged shutters having numbers on their faces corresponding to the number of the clip when thrown up, but adapted to be thrown down over the name-plate holders when no tickets of the kind or class are for sale.

3. The combination of the uprights, the cross-piece bracing the uprights in position, the board between the uprights above said cross-piece, the ticket-clips secured upon said board, the guide-rods secured to said uprights, the screen fitted to slide between said guide-rods to cover or uncover the board, the fixed electromagnet, the armature secured to the screen-frame to hold it in its lower position, the sheaves in the top of said uprights, cords secured to the screen and passing over the sheaves, weights to overbalance the weight of the frame and carry it to its upper position in front of the board, and catches to retain it in the upper position, substantially as shown and described.



605,166. LATHE-CHUCK. ANDREW J. JOHNSON, Cleveland, Ohio, assignor to A. J. Johnson & Co., same place. Filed Oct. 16, 1897. Serial No. 655,402. (No model.)

Claim.—In a device of the character described, the combination of the chuck-body A, adapted to be removably secured to the spindle of a lathe, a sleeve C slidingly engaging the bore of said body A

and adapted to receive a grip-jaw D, the periphery of which is tapered or wedge shape at its outer end, a removable cap B, upon the outer end of the chuck-body A and slidingly engaging said tapered jaws D, oscillating or rocking tumblers E, pivotally secured in the body A with their inner ends engaging the sleeve C, a ring G encircling the body A and in close proximity to the outer ends of the tumblers E, and a non-rotatable ring H, engaging said ring G and provided with trunnions J for engagement with an actuating spanner-lever K, the parts being constructed, arranged and operating in the manner, and for the purpose, substantially as described.

605,167. REDUCING-PRESS. LEWIS J. KINGSLEY, Binghamton, N. Y. Filed June 11, 1897. Serial No. 640,308. (No model.)

Claim.—1. The combination, in a press, of two male and two female dies, mechanism whereby they are caused to approach and recede from each other alternately, one pair of dies being arranged to operate at one end of the stroke, and the other pair at the other end of the stroke, and means whereby the device being operated upon as it emerges from one set of dies will be transferred to the other set of dies for further operation, whereby the same press is caused to perform work while moving in both directions.

2. The combination, in a press, of a reciprocating and two stationary die-supports, the reciprocating support carrying two dies, and each of the stationary supports carrying a single die and arranged upon opposite sides of the reciprocating die-support, and means whereby the article being operated upon as it emerges from one die shall be transferred to the other die.

3. The combination, in a press, of a framework having two heavy transverse bars, one at each end, a male die fixed upon the inner surface of each of said transverse bars, one upon one side and the other upon the other side of a central line drawn through the machine, a reciprocating structure carrying two female dies arranged respectively to operate with said male dies, and mechanism whereby the article being operated upon will as it emerges from the orifice behind one of the female dies be transferred to in front of the other female die ready to be operated by the other male die, substantially as set forth.

4. The combination, in a press, with two stationary dies and a reciprocating die-carrier carrying the dies forming the other members of the press, of a mechanism for transferring the article being operated upon from one pair of dies to the other consisting of a transversely-moving carriage mounted on said reciprocating structure and containing a rock-shaft bearing the gripping-fingers, an arm for preventing said rock-shaft from revolving beyond ninety degrees, and mechanism for operating said carriage.

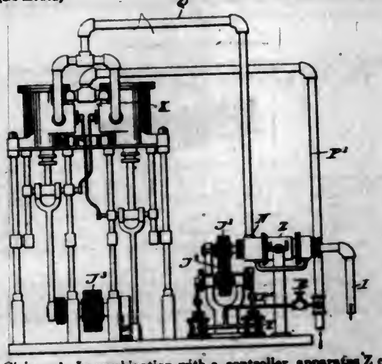
5. The combination, in a press, of three die-carriers one of which has two die parts and the other two one die part each the dies whereof are adapted to operate successively upon the same article, mechanism for driving two of said die parts toward the other two, and a mechanism for automatically transferring the article being operated upon from the first to the second set of dies.

6. The combination, in a double-die press, with the two sets of dies, of a gripper-carriage E, a revoluble shaft mounted in said carriage and carrying the gripper-fingers, a revolution-stopping arm on said shaft whereby its capability of rotary movement is limited, a frictionally-mounted pinion on said shaft, a rack-bar engaging with said pinion, whereby said shaft is revolved during that portion of the travel of said carriage while said revolution-stopping device is free from contact with any adjacent part and is permitted to travel with said carriage without revolving when the revolution-stopping devices are in engagement, and said revolution-stopping devices.

7. The combination, with a double-die press, of mechanism for transferring the article being made from one die to the other consisting of a reciprocating gripper-carriage, a gripper-shaft revolubly mounted therein, a revolution-stopping arm or projection thereon, overhanging projections adapted to engage with said revolution-stopping projection, a loosely-mounted pinion also on said shaft, and a fixed rack-bar alongside said pinion whereby it is caused to revolve, said pinion being thus adapted to revolve said shaft when free from the revolution-stopping devices but to revolve on said shaft when said revolution-stopping devices are in engagement.

8. The combination, in a press, of the framework, the crank-shaft, the fixed die-carriers, the reciprocating die-carrier, the shaft F, the gripper-carriage mounted on the reciprocating die-carrier, a cam on the shaft F for operating said gripper-carriage, and connections from said cam to said carriage, substantially as set forth.

605,168. GAS-REGULATOR. ADOLPH KUEBLER, New York, N. Y., assignor of one-half to James C. Meeks, same place. Filed July 15, 1897. Serial No. 644,627. (No model.)



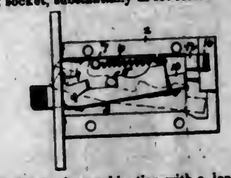
Claim.—1. In a gas-regulator, the combination with a tubular shell, of a hollow, perforated ball freely movable both rotarily and lengthwise therein, substantially as specified.

2. In a gas-regulator, the combination of an outer shell, an inner concentric perforated shell, and a ball movable freely in the former shell, substantially as specified.

3. In a gas-regulator, the combination of an outer shell, an inner concentric perforated shell, and a hollow perforated ball, substantially as specified.

4. In a gas-regulator, the combination of an outer shell, an inner concentric perforated shell, a hollow perforated ball, and a valve situated at the bottom of said inner shell, substantially as specified.

605,169. HYDRAULIC-MOTOR-REGULATING DEVICE. ARTHUR J. L. LORETZ, Brooklyn, N. Y. Filed Apr. 14, 1898. Serial No. 677,567. (No model.)



Claim.—1. In combination with a controller apparatus Z composed of a central chamber B divided into compartments, and arranged with inlet and outlet ports; a double revolving valve, consisting of an inlet disk valve D' and outlet disk valve D², all provided with their respective inlet and outlet ports, and located in their respective balancing-chambers A and C, when all constructed for the purpose herein described.

2. The combination with a hydraulic motor, of a controller which regulates the discharge therefrom at a uniform rate, and means for operating said controller independent of said motor or of the fluid passing therethrough, as herein described.

3. The combination with a hydraulic motor and controller which regulates the discharge therefrom at a uniform rate, and the means for operating said controller independent of said motor or of the fluid passing therethrough; of a valve R whereby the speed of the controller with its operating means is regulated, as herein set forth.

605,170. LATCH. NATHAN J. MEIGS, West Haven, Conn., assignor of one-half to Elmer L. Knowles, New Haven, Conn. Filed July 15, 1897. Serial No. 644,598. (No model.)

Claim.—1. In a door-latch, the combination with a latch-bolt adapted for both longitudinal and a rocking movement, of a knob-spindle adapted for a limited longitudinal movement in a plane at a right angle to that of the movement of said latch-bolt and having means for engaging the latch bolt at one end of its movement to lock the latter against movement, and a striker-plate having a socket to receive the outer end of said latch-bolt and inclined surfaces for causing both an upward and an inward movement of the latch-bolt as it approaches said socket, substantially as set forth.

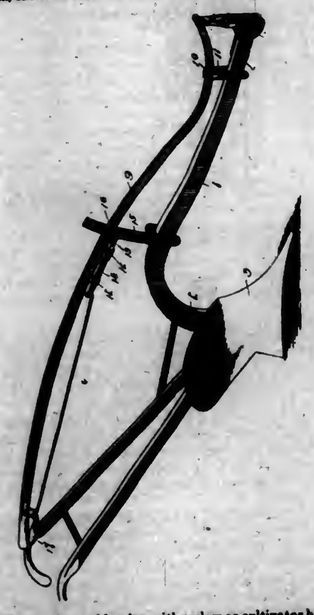
2. In a door-latch, the combination with a longitudinally-movable and pivotally-supported latch-bolt and a spring for imparting outward movement thereto, of a non-revoluble knob-spindle adapted for a limited endwise movement and carrying a lug or projection which, at one extremity of its movement engages the end of said latch-bolt and locks it against inward movement, and a striker-plate having a socket to receive the end of said latch-bolt, an incline for raising the outer end of the latter, and inclined surfaces for forcing the latch-bolt inwardly as it approaches and leaves said socket, substantially as set forth.

3. The combination with the casing 1 having stud 5, of latch-bolt 3 having the recess 4 and ear 9, spring 6, and knob-spindle 12 having the lug 13, substantially as set forth.

4. The combination with the latch-bolt 3 having a V-shaped outer end and provided with the incline 8, of knob-spindle 12 having lug 13, spring 6, and striker-plate 17 having socket 19, incline 21, and inclined surfaces 20 and 22, substantially as set forth.

605,171. DENTAL PLUGGER. FRANCIS S. AVIL, Philadelphia, Pa. Filed Nov. 10, 1897. Serial No. 657,982. (No model.)

Claim.—1. In a dental mallet, a casing, a perforated rotatable collar mounted in the outer end thereof, a nose-piece secured to said collar and rotatable therewith, a point or tool fitted to slide in said nose-piece, a sliding pin in said collar, means for freely connecting said collar with said casing, a plunger, and means for transmitting a blow from said plunger to said pin and consequently to said point.



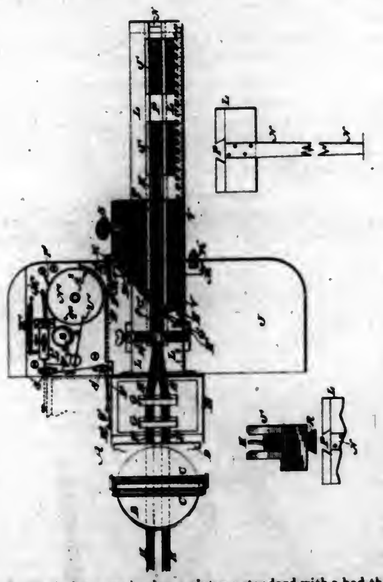
2. In a dental mallet, a casing, a perforated rotatable collar mounted in the outer end thereof, a nose-piece secured to said collar and rotatable therewith, a point or tool fitted to slide in said nose-piece, a sliding pin in said collar, swinging plates at opposite ends of said pin in said nose and casing respectively, and a plunger, the latter being adapted to strike the plate in the casing.

3. In a dental mallet, a casing, a perforated rotatable collar mounted in the outer end thereof, a nose-piece secured to said collar and rotatable therewith, a point or tool fitted to slide in said nose, a sliding pin in said collar, a flanged rim secured to said casing, a plunger, and means for transmitting a blow from said plunger to said pin and from said pin to said point, said collar having a peripheral flange which is freely engaged by said flanged rim.

4. In a dental mallet, having a casing, a nose rotatably mounted thereon, and a movable pin fitted in said casing, swinging plates at opposite ends of said pin, one plate being mounted on said casing and the other plate being mounted on said nose, the plate on the casing being adapted to be engaged by the blow-delivery mechanism of the device, and furthermore adapted to be removed from the action of said mechanism.

5. In a dental mallet, a swinging plate mounted in the casing, adapted to be engaged by the blow-delivery mechanism, and to transmit the blow to the plugger-point or mallet proper, said plate having a finger-piece thereon, which may be engaged from outside of the casing to remove said plate from the action of said mechanism and avoid the impartation of a blow or blows to said point.

605,172. ATTACHMENT FOR PLOWS. JESSE H. BALL, Kendrick, Idaho. Filed June 21, 1897. Serial No. 641,679. (No model.)



Claim.—In combination with a plow or cultivator having a beam, of a clevis pivotally mounted on the front end of the said beam and consisting of opposite side plates connected to each other at their outer ends by a bifurcated bar extended upwardly to form a connection, a bracket supported by the said beam, a lever pivotally mounted in the said bracket and having its forward end attached to the said bifurcated bar of the clevis, a toothed segment over which the rear part of the said lever extends, and a sliding dog mounted on the rear portion of the lever and adapted to engage the toothed segment, the said lever being operated to elevate or depress the clevis and hold the latter in a predetermined adjusted position to regulate the depth of cut of the plowshare in its movement upwardly or downwardly over a hill by changing the draft.

605,178. PRINTING-PRESS FOR CUTTING RIBBONS AND COUNTING SAME. FERDINAND BERKEMEYER, Bellerville, Pa., assignor of one-half to Charles H. Crossman, same place. Filed June 10, 1897. Serial No. 640,148. (No model.)

Claim.—1. In an attachment for a printing-press having a platen, a bed suitably supported on said press, a body portion carried by said bed, a cutter mounted on said body portion, connections from said platen to said cutter, whereby the latter is operated by the movement of the said platen, and means for returning said cutter to its normal position.

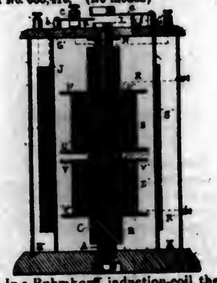
2. In an attachment to a printing-press having a platen, a bed suitably supported on said press, a groove in said bed, a body por-

tion having a tongue entering said groove and carried by said bed, a cutter mounted on said body portion, connections between said cutter and platen, whereby the latter is operated by the movement of said platen and means for returning said cutter to its first position.

3. A printing-press having a platen a standard with a bed thereon, a block having a tongue movable in a groove in said bed, guides on said block forming a passage-way, a cutting device on said block, and a flexible connection from the movable member of said cutting device to the movable platen of a printing-press.

4. In an attachment to a printing-press having a platen, a bed suitably supported on said press, a body portion carried by said bed, means for adjusting said body portion thereon, a cutter mounted on said body portion, means for operating said cutter means for returning said cutter to its normal position, and an adjustable guide mounted on said body portion.

5. In an attachment to a printing-press, having a platen, guides thereon, a bed suitably supported on said press, a groove in said bed, a body portion having a tongue entering said groove, had carried by said bed, means for adjusting said body portion thereon, a cutter mounted on said body portion, means for operating said cutter means for returning said cutter to its first position, and an adjustable guide mounted on said body portion.



6. In an attachment to a printing-press having a platen, a bed suitably supported on said press, a groove in said bed, a body portion having a tongue entering said groove and carried by said bed, means for adjusting said body portion thereon, a cutter mounted on said body portion means for operating said cutter, means for returning said cutter to its first position, an adjustable guide mounted on said body portion, and a registering device operated by the movement of the platen.

7. An attachment to a printing-press for the purpose set forth, consisting of a block having a body with a tongue thereon and provided with guides in its upper face forming an adjustable passage-way, one end of said body being at an oblique angle to its sides, and provided with a cutting device having connections with the movable platen of the press for operating the same.

8. A printing-press having a movable platen, a standard with a bed thereon, a block having a tongue adjustable in a groove in said bed, guides on said block forming a passage-way, a cutting device on a slanting end of said block, a movable member provided with a flexible connection adapted to be secured to the said platen.

9. The swinging platen E with guides G having openings therein, the bed L with the groove N therein, the block Q having the tongue R in said groove and provided with the clamping-screw S, a cutting device having a movable member C' with flexible connection D' secured to said platen E, the returning-spring G', for said member, the guide K' movably secured to said bed L, and the fixed guide T and adjustable guide U forming the passage-way W.

605,174. INDUCTION-COIL. ADRIAN L. BOGART, Jamaica, N. Y., assignor to William R. M. Jordan, New York, N. Y. Filed Apr. 22, 1897. Serial No. 633,416. (No model.)

Claim.—1. In a Ruhmkorff induction-coil, the combination with the primary and secondary coils, of a condenser arranged in the same plane therewith and partially inclosing the same, substantially as set forth.

2. In an induction-coil, the combination of a primary and secondary, with a condenser and an interrupter comprising an armature mounted upon a relatively light spring, a second and heavier spring carrying a movable contact-point and arranged in the path of movement of the first spring, and a fixed contact-point normally making contact with said movable contact-point, substantially as set forth.

3. In an induction-coil, the combination with a base and head, of a bolt securing the same and surrounded by the primary and secondary, a casing of insulating material inclosing the said primary and secondary, and a condenser located upon said casing, substantially as set forth.

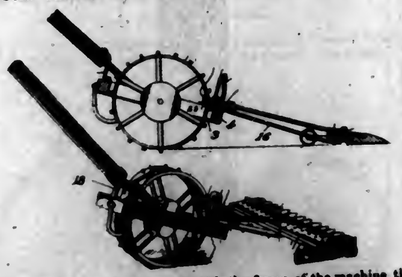
4. In an induction-coil, the combination with the primary coil, of a secondary coil in sections, each section comprising an insulating-spool with its conductor wound thereon, several sections being properly connected, and a condenser partially inclosing said primary and secondary coils, substantially as set forth.

5. In an induction-coil, the combination with the primary and secondary, of a casing inclosing the same, a condenser adjacent to said casing, and an outer casing surrounding the whole, with a base and top inclosing the ends of said casing, to which said casings are secured, substantially as set forth.

6. In an induction-coil, the combination with the working parts of a head and base, a bolt or bolts connecting the same, a condenser partly inclosing the coils and a casing inclosing the condenser and coils and held in place by the head and base, substantially as set forth.

7. An interrupter for induction-coils, comprising an armature mounted upon a relatively light spring, a second and heavier spring carrying a movable contact-point and arranged in the path of movement of the first spring, and a fixed contact-point normally making contact with said movable contact-point, substantially as set forth.

605,175. PORTABLE COAL-SIFTER. LUDIE BUCHTEL, New York, N. Y. Filed Mar. 11, 1897. Serial No. 626,963. (No model.)



Claim.—1. A portable coal-sifter comprising a casing provided with a cylindrical body having an upper section formed with a horizontal peripheral lower flange, and a lower section formed with a horizontal peripheral upper flange, the perforated diaphragm located between the peripheral flanges, secured thereto and projecting beyond the flanges to provide a peripheral collar whereby the casing is lifted for removing and replacing the sifter; the removable cover, and a stirrer journaled in the diaphragm and in the cover, substantially as described.

2. A portable coal-sifter comprising a casing provided with a cylindrical body, and a perforated diaphragm, the conical covering having a circular opening at its apex, the bushing having a beveled socket at its lower end and secured in the circular opening, the stirrer-stem formed with an upwardly-tapering enlargement fitting in the beveled socket, a bearing-bar for the lower end of the stirrer-stem, and a stirrer-head secured to the stirrer-stem; substantially as described.

3. A portable coal-sifter comprising a stirrer having a stem formed with side recesses near its lower end, and a head consisting of three twisted radial arms, each having a gathering-lip at its outer end, two of the arms being formed in one piece and fitted in one of the side recesses, and the other arm having an angular extension fitting in the other recess and also against one of the other arms, a bolt extending through the angular extension through the stirrer-stem and through the integral arms, and a bolt extending through the extension and through one of the integral arms; substantially as described.

605,176. LAWN-MOWER. WILLIAM W. CROCKETT, Falls City, Nebr. Filed Sept. 14, 1897. Serial No. 651,630. (No model.)

Claim.—1. The combination with the frame of the machine, the operating-wheel journaled in suitable bearings in said frame and provided with a sinuous groove, and the reciprocating cutter, of means for giving the motion to the cutter when the operating-wheel is rotated, and an arm or finger secured to the frame and extending into the groove to keep the same clear, substantially as and for the purpose set forth.

2. In a mower, a movable cutter, a sway-bar pivoted to the mower-frame and having its front end connected to the cutter, means for vibrating the sway-bar, a support above the sway-bar, a link pivoted to the said support having at its lower end a foot pressing upon the sway-bar, for the purpose set forth.

605,177. INKSTAND. EBEN DAVIS, New York, N. Y. Filed June 19, 1897. Serial No. 641,057. (No model.)

Claim.—1. An inkstand comprising the combination of an exteriorly-cylindrical air-filled funnel-float centrally tubular, and an interiorly-cylindrical reservoir provided with a base, and in which the float closely fits to slidably engage the interior walls thereof, the said float being of a form and adapted to substantially wholly occupy the interior of said reservoir whereby air is excluded from said fluid other than through the center of the float, substantially as shown and described.

2. An inkstand formed of a cylindrical body or reservoir provided with a base 6, and an annular flange 8, at top in combination with an exteriorly-cylindrical float substantially occupying the interior of the reservoir and fitting wholly within the same, the said float being provided with an annular flange 14 at top adapted to rest upon and project above the flange 8 of the reservoir, and the said float being vertically movable in and freely removable from the said reservoir, substantially as shown and described.

3. In an inkstand, a reservoir consisting of a cylinder open at the top and provided with a closed lower end supported by a base, in combination with a funnel-float having exteriorly longitudinal and lateral dimensions and form approximately corresponding to those of the interior of the reservoir, substantially as shown and described.

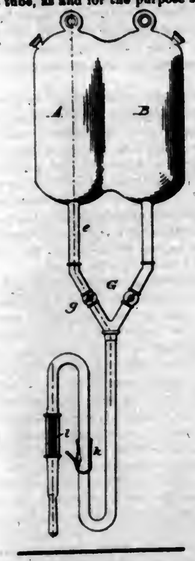
4. In an inkstand, the combination with a reservoir having a uniform width at and upward from the bottom thereof, and open at the top throughout its width, of a centrally-tubular air-filled float having exterior longitudinal and lateral dimensions and form approximately corresponding to those of the interior of the reservoir, whereby the whole of said reservoir is occupied by the float, the said float normally resting upon the bottom of said reservoir and projecting above the top of the same, whereby it is adapted to deliver the ink from its lowest level, without the top of said float being movable below the top of the reservoir or below the ink at its highest level, and the delivery of said float being wholly from the center thereof, said float fitting closely in the reservoir whereby the walls of the same engage therewith.

5. An inkstand consisting of an interiorly-cylindrical vertical reservoir, and a hollow cylindrical air-filled float mounted therein and closely fitting said reservoir, and adapted to move vertically therein, and consisting of an outer tube, the upper end of which is closed by a conical cap, the base of which extends upwardly, and the apex of which extends downwardly and inwardly and is provided with a tubular extension which projects downwardly and centrally through said outer tube, said outer and inner tubes being each open at the bottom, the longitudinal and lateral dimensions of the float being substantially equal to the corresponding dimensions of the interior of the reservoir, substantially as shown and described.

6. An inkstand consisting of an interiorly-cylindrical vertical reservoir, and a hollow cylindrical air-filled float mounted therein and closely fitting said reservoir, and adapted to move vertically therein, and consisting of an outer tube, the upper end of which is closed by a conical cap, the base of which extends upwardly, and the apex of which extends downwardly and inwardly and is provided with a tubular extension which projects downwardly and centrally through said outer tube, said outer and inner tubes being each open at the bottom, the longitudinal and lateral dimensions of the float being substantially equal to the corresponding dimensions of the interior of the reservoir, and said reservoir being provided at the top thereof with an annular overflow-chamber, the inner wall of which is formed by said float, substantially as shown and described.

7. In an inkstand the combination with a reservoir wholly open at the top, and interiorly cylindrical, of an exteriorly-cylindrical hollow air-filled float, having a central vertical delivery, said float laterally fitting the walls of the reservoir, and longitudinally formed so that when resting upon the bottom of the reservoir it will project above the top of the same, the upper end of said float being provided with an annular flange whereby the upper portion of said float and said flange conjunctively form the closure of the open top of the reservoir.

8. An inkstand consisting of two parts one adapted to receive the other within it, the same being wholly open at one end and closed at the other, said part forming the ink-reservoir, and the other part of the device being formed to telescope within said first part or reservoir, and closely fit the wall thereof, said part being of a length corresponding with the depth of the reservoir and being provided with a flange to limit the telescoping of the parts and permit their mutual detachment, said inner part being adapted to deliver or supply the ink, and being formed into a funnel at the top, into a float throughout its length, and into a tube throughout its center.



9. In an inkstand the combination with a float of the character described, of a reservoir formed to receive the said float within it, and to closely surround the same, said reservoir being provided with a base on which said float is adapted to rest, and extending approximately to the top of said float, said reservoir being of a uniform width throughout the major portion of its interior, and being of an increased width at the top thereof to form a vertical annular groove or recess itself of uniform width, said upper recessed portion of the reservoir being wholly open at the top to permit the free insertion and removal of the float.

605,178. FOUNTAIN-SYRINGE. FRANK C. FERGUSON, Indianapolis, Ind. Filed Feb. 2, 1897. Serial No. 621,654. (No model.)

Claim.—1. A fountain-syringe consisting of a chambered bag, each chamber having at its upper portion an induction-opening and at its lower portion an eduction or discharge tube, a branched, or Y-shaped discharge-tube coupled to the eduction-tubes depending from the bag, a pair of turn-valves, one of each located in the upper branched portion of the Y-shaped tube, a transparent cylinder or tube connected with and depending from the discharge end of said tube, a thermometer located in said transparent tube or cylinder and a discharge-nozzle connected with the lower end of said cylinder, as and for the purpose set forth.

2. A fountain-syringe consisting of a divisional or chambered receptacle having induction and eduction nozzles or posts connected with the respective divisions or chambers, a discharge-tube having a Y-shaped branched portion connected with said eduction-nozzles and having a valve in each branch, a transparent tube or cylinder connected at its inner end with the lower, or outer, end of said discharge-tube, a pair of transversely-bored soft-rubber disks contained and frictionally held within said transparent tube, a thermometer passed through and flexibly supported by said rubber disks within said transparent

tube, and a discharge-nozzle connected with the lower, or outer, end of said transparent tube, as and for the purpose set forth.

605,179. BOTTLE-WASHER. CHARLES H. FISCHER and HENRY R. FISCHER, Cincinnati, Ohio. Filed Mar. 6, 1897. Serial No. 626,205. (No model.)

Claim.—1. In a bottle-scouring device, the combination of a vessel containing the scouring medium, a continuous water-pipe entering and passing through said vessel, terminating above it in a discharge-nozzle, having lateral openings in its wall at such height as to be within that part of the vessel occupied by the scouring medium, so that when water is permitted to pass through said pipe, portions of the scouring medium are drawn in through said lateral openings and a bottle-support for sustaining the bottle in an inverted position above the discharge end of said pipe.

2. In a bottle scouring and rinsing device the combination of a vessel 8, pipes 9 and 12, the former having openings 11 in its wall for communication with vessel 8, the two pipes ending in a single discharge spout or nozzle, a support for sustaining a bottle in an inverted position above the latter, a spreader 19 secured to pipe 9 below this support, a pipe 13 supplying pipes 9 and 12, and a cut-off device for admitting the supply to either one of these pipes.

3. In a bottle scouring and rinsing device, the combination of a vessel 8 to receive the scouring medium, two continuous pipes 9 and 12 passing through the former, pipe 9 having openings 11 in its wall at such height as to be in communication with vessel 8 to admit the scouring medium, the two pipes connected above holes 11 to form a single discharge spout or nozzle, a support for sustaining a bottle in an inverted position above the latter, a pipe 13 supplying pipes 9 and 12 and a cut-off device for admitting the supply to either one of the pipes.

4. In a bottle scouring and rinsing device, the combination of a vessel 8, pipes 9 and 12, the former having openings 11 in its wall for communication with vessel 8, the two pipes ending in a single discharge spout or nozzle, a support for sustaining a bottle in an inverted position above the latter, overflow-openings in vessel 8, a shield 21 in front of them, a pipe 13 supplying pipes 9 and 12 and a cut-off device for admitting the supply to either one of the pipes.

605,180. BOTTLE-WASHER. HENRY R. FISCHER and CHARLES H. FISCHER, Cincinnati, Ohio. Filed Nov. 15, 1897. Serial No. 658,590. (No model.)

Claim.—1. In a bottle-cleaning device, the combination of a vessel to contain the scouring medium, a water-pipe passing through the same, having lateral openings which communicate with the lower part of the vessel, means to open and close these openings and supporting means for holding an inverted bottle above the discharge end of the water-pipe.

2. In a bottle-cleaning device the combination of a vessel 13 a water-pipe 8, lateral openings 14 therein, lids 16 for these openings means to open and close them and a support for holding an inverted bottle above the water-pipe.

3. In a bottle-cleaning device, the combination of a vessel 13 a water-pipe 8, lateral openings 14 therein, lids 16 for these openings levers 28 which carry these lids, means to swing the levers for closing or uncovering openings 14 and a support for holding an inverted bottle above the water-pipe.

4. In a bottle-cleaning device, the combination of a vessel 13 a water-pipe 8, lateral openings 14 therein, lids 16 for these openings, levers 28 which carry these lids, a cam-plate 32 with an accessible handle for operating these levers to open or close openings 14 and a support for holding an inverted bottle above the water-pipe.

5. In a bottle-cleaning device the combination of a vessel 13, a water-pipe 8, lateral openings 14 therein, lids 16 for these openings means to open and close them, a spreader 22 supported on pipe 8 and a support for holding an inverted bottle above the water-pipe.

6. In a bottle-cleaning device, the combination of a vessel 13 a water-pipe 8 having lateral openings 14, a member 17 superposed upon vessel 13 to add to the height of the latter and provided with overflow-openings 18 and a support for holding an inverted bottle above the water-pipe.

7. In a bottle-cleaning device, the combination of a vessel 13, the height of which is increased by the superposition of additional members fitted thereto, a water-pipe 8 having lateral openings 14, and the curved spring-wire bottle-supports 26 projecting upwardly and turned over the uppermost member and extending downwardly within the same.

8. In a bottle-cleaning device, the combination of a vessel 13, a water-pipe 8 having lateral openings 14, a member 17 superposed upon vessel 13 to add to the height of the latter and provided with overflow-openings 18 an annular drain-gutter 19 with waste-pipe 21 below them and a support for holding an inverted bottle above the water-pipe.

9. In a bottle-cleaning device, the combination of a series of vessels 13, a water-pipe 8 for each, a supply-pipe 11 for all these water-pipes, lateral openings in these latter, means to open and close them, a connecting-rod attached to these means in a manner to cause all of them to operate together, and bottle-supports above each vessel.

10. In a bottle-cleaning device, the combination of a series of vessels 13, a water-pipe for each, a supply-pipe 11 for all these water-pipes, lateral openings 14 in these latter, bottle-supports above each vessel, a superposed member 17 on each of the latter to increase their height overflow-openings in them and a drainage-gutter with waste-pipe surrounding the whole series of vessels below the overflow-openings in the latter.

11. In a bottle-cleaning device the combination of a vessel adapted to contain the scouring medium, a water-pipe communicating with the same, supporting means for holding an inverted bottle above the discharge end of the water-pipe and a tip on this latter so mounted as to be capable of being rotated by the force of the discharging current.

12. In a bottle-cleaning device, the combination of a vessel 13, a water-pipe 8 having lateral openings 14, a member 17 superposed upon vessel 13, to add to the height of the latter and provided with overflow-openings 18, a guard 23 interposed in front of them and a support for holding an inverted bottle above the water-pipe.

605,181. BICYCLE-WHEEL BELT. WILLIAM F. GLIDDEN, Ingersoll, Canada. Filed Jan. 23, 1896. Serial No. 576,618. (No model.)

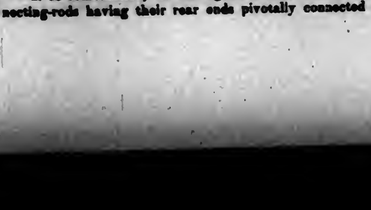
Claim.—1. In a bicycle-wheel belt, a flexible shield which fits snugly over the tire of the wheel, and two series of straps secured to the shield, and extending laterally thereto, combined with cords which connect the outer ends of the extensions at a suitable distance from the edge of the shield, substantially as shown.

2. A belt composed of the shield, A, straps, B, provided with the loops or eyes, B', and the cords, C, in combination with and extending around a wheel-tire and over an antifriction roller or pulley, and means for supporting the latter, the periphery or outer face of the antifriction roller or pulley being wider than the periphery or outer face of the wheel-tire for the purpose of spreading the belt as it passes from and on to the wheel-tire to prevent the latter from being rubbed or injured, substantially as set forth.

3. In a bicycle, a belt, the front wheel around which the belt extends, and an antifriction-roller arranged over the wheel, and over which roller the belt passes, combined with a supporting-spring for the roller, and which spring extends over the top of the wheel; an eccentrically-pivoted bearing which supports the spring at a point in between its two ends, and by which the tension of the roller upon the belt is regulated; and means connected to the inner end of the spring for securing it in position, substantially as shown.

4. A belt consisting of a shield, A, straps, B, provided with the loops or eyes, B', and cords, C, extending around the tread of the wheel-tire and over the antifriction roller or pulley, in combination with a spring, and an eccentrically-pivoted bearing and means for supporting and operating the latter, substantially as and for the purpose set forth.

5. In a bicycle, the front forks D, D, the standards E, E, secured thereto at their lower ends and projecting upwardly, and the braces 1, 1, connected both to the forks at one end, and to the standards at the other, combined with a shaft G which passes through both the braces and the forks, a spring, means for securing it to the bicycle-frame, a roller supported by its front end, a belt, the front wheel of the bicycle around which and pulley, the belt passes; an eccentric bearing placed upon the shaft, a suitable support for the front of the eccentric bearing, and a support for the forks I, which is attached at its upper end to the support for the bearing, substantially as shown.



6. The front forks D, D, the standards E, E, secured thereto at their lower ends, the braces I, I, secured to the forks at their rear ends, and to the upper ends of the braces at their front ones, the rod G which connects the front ends of the braces and the front ends of the standards, combined with an eccentric bearing that is pivoted upon the rod at its rear end, a support for the front edge of the bearing, a support which is secured to the forks at its lower end, and connects at its upper end with the support for the front edge of the bearing, a spring that rests upon the eccentric bearing and has its rear end secured to the forks by means of the vertical support, a pulley attached to the outer end of the spring, and a belt which passes around the front wheel of the bicycle, and pulley, substantially as shown.

7. In a bicycle-frame, the standards E secured thereto at their lower ends, the braces I secured to the frame at their rear ends, and the rod G which connects the front ends of the braces and the upper ends of the standards, combined with an eccentrically-pivoted bearing placed on the rod; a spring resting upon the bearing, the pulley secured to the outer end of the spring, a support which rises from the braces and serves to connect the inner end of the spring to the braces, substantially as described.

8. The bicycle frame, the standards E, the braces I, and clasps for securing the standards and the braces to the frame, and the rod G for rigidly connecting the ends of the standards and the braces, combined with an eccentrically-pivoted bearing, means for regulating the position of the bearing, a spring resting upon the bearing, means for connecting the spring to the bicycle-frame, a roller secured to the outer end of the spring, and a belt which passes around the roller and the wheel of the bicycle, substantially as described.

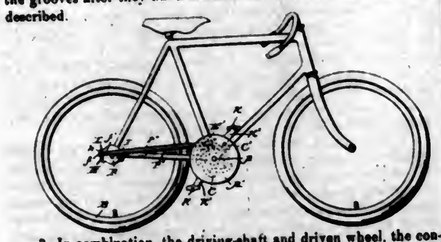
9. In a bicycle, the standards E, the crossed braces I, suitable clasps for connecting the standards and braces to the bicycle-frame, the rod G for connecting the ends of the standards and braces, and the eccentrically-pivoted bearing, having a rounded top and end flanges, combined with a flat spring that has its rear end secured to the braces, a roller secured to its outer end, a belt which passes around the roller, the rod d which passes through the spring and secures it to the braces, and the rod d^3 connected to the bearing and provided with means at its upper end for holding the bearing in any desired position, substantially as shown.

605,182. BICYCLE. AMBER JOHNSTON, Jersey City, N. J., assignor of five-eighths to George B. Fielder, same place, and E. Guy Foster, New York, N. Y. Filed Apr. 8, 1897. Serial No. 631,908. (No model.)

Claim.—1. In a bicycle, the front wheel having its hub provided with a slot which extends from the center, radially toward one edge thereof, combined with the front axle, which passes through the slot, and is adjustable therein, and means for rigidly securing the axle in any desired position in the slot, whereby the front end of the frame is given a rising-and-falling movement when the bicycle is in motion, substantially as shown.

2. In a bicycle, a hub of a wheel having slots made therein, and which slots have notches along their edges, combined with an axle-bearing which passes through the slots, and supporting devices for said bearing, provided with means for catching in the notches and supporting the axle-bearing in any desired position, whereby the position of the axle with relation to the center of the wheels is changed, substantially as described.

3. In a bicycle the combination of the frame, the hub of the front wheel composed of end plates having openings 10 and 11, an axle-bearing having flange 13 to rest against the inner side of said plates, and having a projection extending out of said plate to hold the washer 16 having lugs 17 which enter corresponding openings 11 in said plate, an axle passing through said axle-bearing, as and for purposes set forth.



4. In a bicycle the combination of the frame, the hub of the front wheel composed of plates 5 and 6 having an opening 10 through which the axle-bearing passes, a washer 16 having lugs 17 on the inner side to correspond with and enter the openings 11 on said plate, nuts to hold said washer and axle-bearing in place, an axle 23 passing through said axle-shell and secured to front fork of said frame, substantially as set forth.

605,188. DRIVING CONNECTION FOR BICYCLES. HUGH W. JOHNSTON, Atlanta, Ga., assignor of one-half to Paul H. Johnstone, Idylwild, Ga. Filed Mar. 12, 1897. Serial No. 627,191. (No model.)

Claim.—1. In combination with the driving-shaft and driven wheel, the connecting-rods having their rear ends pivotally connected to the driven wheel, disks upon the driving-shaft having continuous ways in their faces provided with approximately radial portions forming shoulders, the forward ends of said connecting-rods having a sliding connection with the ways and being arranged to alternately engage with said shoulders to exert a longitudinal pull upon the rods during the entire forward movement thereof, and to be released therefrom to permit the rods to move freely backward to their initial position, substantially as described.

2. In combination, the driving-shaft and driven wheel, the connecting-rods having their rear ends pivotally connected with the

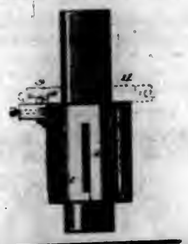
driven wheel, the disks upon the driving-shaft having grooves in their faces with angular portions forming shoulders, extensions or offsets upon the forward ends of the rods adapted to alternately engage said shoulders and slide in the intermediate portions of the grooves, and means for holding the ends of the rods against reverse movement in the grooves after they have reached the shoulders, substantially as described.

3. In combination, the driving-shaft and driven wheel, the connecting-rods having their rear ends pivotally connected with the driven wheel, the disks upon the crank-shaft having continuous grooves in their faces with approximately radial portions forming shoulders, extensions or offsets upon the forward ends of the rods traveling in the grooves adapted to alternately engage the shoulders to exert a pull upon the rods and to disengage the shoulders to permit the rods to move rearwardly, and means for preventing the disengagement of each rod from the shoulders until the rear wheel has made a semirevolution, substantially as described.

4. In combination, the driving-shaft and driven wheel, the disks or crank-arms carried by the driven wheel, the disks on the crank-shaft, having continuous grooves in their faces provided at intervals with shoulders, connecting-rods pivotally connected to the disks on the driven wheel and having extensions or offsets at their front ends adapted to travel in the grooves and alternately engage the shoulders, and slide in the intermediate portions of the grooves, and springs carried by the disks of the rear wheel adapted to engage the end of the rod in rear of its pivot and prevent the front end from disengaging the shoulders until the driven wheel has made a semirevolution, substantially as described.

5. In combination, the driving-shaft and driven wheel, disks carried by said parts, continuous grooves in the faces of the driving-shaft disks having shoulders at intervals, connecting-rods pivotally connected at their rear ends to the driven-wheel disks or crank-arms and having offsets at their front ends adapted to travel in the grooves and to engage the shoulders, and springs carried by the driven-wheel disks and adapted to engage the rods in rear of their pivots, said rods having recessed portions to permit the passage of said springs in front of the said pivots, substantially as described.

6. In combination, the driving-shaft and driven wheel, disks carried by said parts, continuous grooves in the faces of the driving-shaft disks having shoulders at intervals, connecting-rods pivotally connected at their rear ends to the driven-wheel disks or crank-arms and having offsets or extensions traveling in the grooves of the driving-disks and adapted to alternately engage the shoulders and to disengage the same and slide in the intermediate portions, and pawls located in proximity to the shoulders adapted to engage the rods and hold them against reverse movement until the rear wheel has made a semirevolution, substantially as described.



7. In combination, the driving-shaft, the driven wheel, the disks carried by the driving-shaft having grooves in their faces provided at intervals with approximately radial shoulders, the connecting-rods having their rear ends pivotally connected to the rear wheel, and having offsets traveling in the grooves and adapted to abut against the shoulders to exert a longitudinal pull upon the rods, said grooves having overhanging edges adapted to retain the offset ends in the grooves, substantially as described.

605,184. RECESSING-TOOL FOR LATHES. GEORGE R. MILLER, Middletown, Pa., assignor of one-half to John W. Allright, same place. Filed Dec. 18, 1896. Serial No. 616,180. (No model.)

Claim.—1. In a recessing-tool, the combination with a tap having a recess or pocket, of a tool-holder carried thereby provided with a tenon engaging said recess or pocket and with a tool slot or opening, independently-adjustable recessing and facing tools superposed one in relation to the other and in diametrical relation to the tap in said opening, and a clamping-screw passing through the tool-holder and binding on said tools.

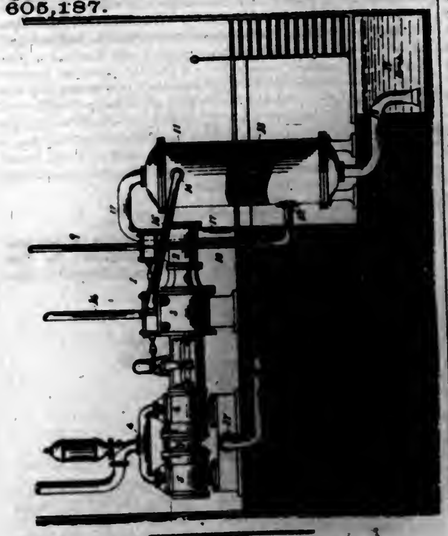
2. In a recessing-tool, the combination with a tap, of a tool holder or post having a portion received in said tap, a screw whose shank passes through the tap and into the post and is adapted for holding the latter in position, and a tool secured in said tool-holder.

3. In a recessing-tool, the combination with a tap provided with a recess, of a tool holder or post having a reduced portion which fits in said recess and said post extending diametrically in relation to the tap and provided with an opening, an inclined screw whose shank passes through the tap and into the reduced portion of the post, independent recessing and facing tools located in the holder, and a clamping-screw threaded into the said post or holder and binding on the tools.

605,185. BRUSH. HORACE R. MILLER, Newark, N. J., assignor to The Celluloid Company, New York, N. Y., a Corporation of New Jersey. Filed Feb. 12, 1897. Serial No. 623,063. (No model.)

Claim.—A back for brushes, consisting of (1) an upper half-shell which has sufficient raised portions to support a metal covering on its exterior surface, and (2) a lower half-shell into which the bristles are drawn or attached: both half-shells being composed of a pyroxylin compound and secured together at their meeting edges; in combination with an upper thin sheet of metal which approximately fits over the raised portions of the surface of the upper half-shell and has its edges folded over upon the edges of the lower half-shell and is secured thereto, substantially as described.

605,186. WICK-LIFTING DEVICE. WILLIAM A. PENFIELD, Meriden, Conn., assignor to the Bradley & Hubbard Mfg. Co., New Haven, Conn. Filed Oct. 25, 1897. Serial No. 656,269. (No model.)



Claim.—In a wick-lifting device for central-draft lamps, the combination with a pair of horizontally-arranged cast-metal jaws, each of which has a transversely-arranged spring-recess formed in its upper face, and with an outwardly-projecting extension located in line with the said recess, a transversely-arranged spiral spring located in the said recesses of the jaws, and connected at its outer ends with the outer ends of the said extensions, and a vertically-arranged drawbar with the lower ends of which one or both of the said jaws is pivotally connected.

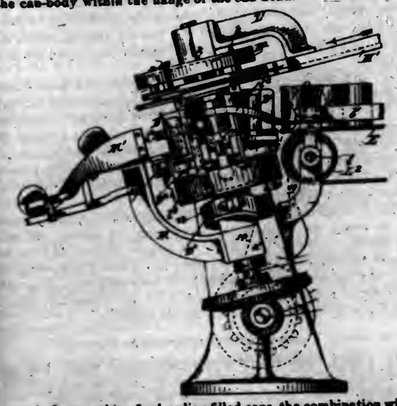
605,187. PNEUMATIC PUMPING-ENGINE. EDWARD A. REX, San Francisco, Cal. Filed July 16, 1897. Serial No. 644,812. (No model.)

Claim.—In combination with the high and low pressure cylinders of a pneumatic engine, a water-pump driven thereby, and a chamber or vessel provided with two sets of adjacent passages, through one set of which passes the water being pumped, the other set being connected on one side with the exhaust of the high-pressure air-cylinder, and on the other side with the inlet of the low-pressure air-cylinder, whereby the temperature of the high-pressure exhaust-air is raised by that of the water being pumped, substantially as specified.

605,187.

605,188. BUNDLE-CARRIER FOR BICYCLES. CARL ROSDELL, Minneapolis, Minn. Filed Mar. 18, 1897. Serial No. 628,102. (No model.)

Claim.—1. A bundle-carrying attachment for cycles, comprising a fixed bed or bottom section, a pair of spring-closed leaves or wings, hinged to the opposite sides of said bed-section and folding toward each other, and means for securing said bed-section to the cycle, substantially as described.



2. A bundle-carrying attachment for cycles, comprising a fixed bed-section, a pair of leaves or wings hinged to the opposite sides of said bed-section and folding toward each other, means for simultaneously opening both of said wings, and means for securing the bundle-carrier to the cycle, substantially as described.

3. A bundle-carrying attachment for cycles, comprising a bed or bottom section, a pair of clamping-leaves hinged to said bottom-section and under spring tension to close, a handpiece with link-and-lever connections to said leaves, for simultaneously opening the same, said connections involving slot-and-pin joints, which permit the said leaves to be opened independently when force is applied thereto, substantially as described.

4. An attachment for cycles, comprising the pair of parallel pronged brackets, the prongs of which are securable to the prongs of the front fork of the cycle, the bed or bottom section secured to the upper prongs of said brackets, and the pair of spring-closed leaves or wings hinged to said bed-section, substantially as described.

605,189. CAN ENDING OR HEADING MACHINE. HENRY SCHAAER, New Westminster, Canada. Filed Oct. 27, 1897. Serial No. 656,541. (No model.)

Claim.—1. In a machine for heading or ending filled cans, the combination with the rotating shaft, of the hub fastened thereon, the vertical can-holders, the can-head holders, of mechanism for placing the filled cans in the holders in a vertical position and of devices for moving the can-holders toward the can-head holders in order to place the inner edge of the can within the inner portion of the flange of the retained can-head and throwing the can-holders from an inclined position into a vertical position, so as to force the entire circumference of the can-body within the flange of the can-head.

2. In a machine for heading filled cans, the combination with the rotary shaft, of the hub fastened thereto, the vertical slide-plates working within guide-channels in the hub, the can-holders fulcrumed at one end to the slide-plates, the can-head holders connected to the rotary shaft, of devices for imparting a vertical reciprocating movement to the slide-plates so as to move the can-holders toward and from the can-head holders, and of devices for throwing the can-holders from an inclined to a vertical position so as to force the entire circumference of the can within the flange of the retained can-head.

3. In a machine for heading cans, the combination with the rotary shaft, of the can-head holders connected therewith, the vertically-movable slide-plates carried by the rotary shaft, the can-holders fulcrumed to the slide-plates, devices for imparting a vertical movement to the slide-plates to raise and lower the can-holders, and of the device for forcing the headed or ended can from within the can-holders.

4. In a machine for heading cans, the combination with the rotary shaft, of the can-head holders connected to and carried by said shaft, the movable face-plate hinged to the stationary section of the can-head holder, devices for throwing the movable face-plate inward and outward in order to lock and release the can-head, and of the plunger-rod for forcing the headed can-body from within the can-head holder.

5. In a machine for heading cans, the combination with the vertically-movable slide-plates, of the can-holders fulcrumed thereto, the can-head holders, of mechanism for moving the slide-plates toward and from the can-head holders, and of devices for throwing the can-holders from an inclined to a vertical position.

6. In a machine for heading cans, the combination with the vertically-movable slide-plates, of the can-holders fulcrumed at one end to the slide-plates, the can-head holders, mechanism for moving the slide-plates toward and from the can-head holders and moving the can-holders from an inclined to a vertical position, and of devices for forcing the headed can from within the can-holder.

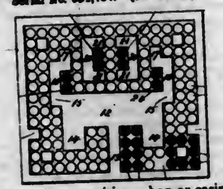
7. In a heading-machine for cans, the combination with the rotary shaft, of a series of cam-rings, each having an eccentric groove therein, the hub fastened upon the rotatig shaft, vertically-movable slide-plates working within a guide-channel formed in the hub of the rotating shaft, a roll connected to the slide-plates, the can-holder fulcrumed at one end to the slide-plates, a roll secured to an arm projecting from the can-holder, the roll of the can-holder and slide-plate working in eccentric grooves, the can-head holder connected to the rotating shaft, the movable face-plate secured thereto, the roll secured to an arm projecting from the movable face-plate, a cam-ring having an eccentric groove therein within which the said roll works, and of devices for forcing the headed end of the can from within the can-head holder and the can from within the can-holder.

8. The combination with the fulcrumed can-holders, of mechanism for throwing the can-holders from an inclined to a vertical position, of the can-extracting device working within the can-holders and of devices for moving the extracting device in and out of the said can-holder.

9. The combination with the rotating shaft, of the can-head holders carried thereby, the movable can-holders, mechanism for imparting rotary motion to the said shaft, the can-conveyer or feed-belt which delivers filled cans to the holders, mechanism for driving the conveyer or feed-belt at a higher speed than the rotating shaft, and of devices for moving the can-holder toward and from the can-head holders.

10. The combination with the rotating shaft, of the can-head holders secured thereto, the fulcrumed can-holders, devices for imparting vertical movement to the can-holders, mechanism for delivering filled cans to the can-holders in a vertical position, and of devices for retaining the cans in the can-holders during the heading operation.

11. In a machine for ending or heading cans, the combination with the rotating shaft, of the vertical can-holders secured to and carried thereby, the can-head holders carried by the shaft, devices for moving the can-holders toward and from the can-head holders, the can-conveyer or feed-belt which delivers cans to the can-holders during the rotary travel thereof, and of mechanism for imparting greater speed to the conveyer or feed-belt than to the rotary shaft carrying the can and can-head holders.



12. In a machine for ending or heading cans, the combination with the rotary traveling mechanism carrying can-holders, and can-head holders, of devices for moving can-holders toward and from the can-head holders, during the travel of the rotary traveling mechanism, and of the can-conveyer or feed-belt for delivering the cans to the can-holders in a vertical position, said conveyer or feed-belt traveling at a greater speed than that of the can-holders.

605,190. PROCESS OF PREPARING LIQUID FOOD. WILLIAM BELLHAM, Darking, England. Filed Dec. 27, 1897. Serial No. 663,778. (No specimens.) Patented in England Feb. 5, 1897, No. 3,095.

Claim.—1. The process or method herein described of manufacturing a food product which consists in placing new-laid eggs in their shells in a receptacle, covering said eggs with lemon peel and juice, placing more eggs in their shells in the receptacle and covering with orange-juice and salt, to assist in dissolving the egg-shells; hermetically sealing the receptacle for seven days; adding to this mass castor sugar, extract of beef, mutton, rabbit and chicken, crushed cereals, cream, boiling milk, honey and cognac, thoroughly mixing and filtering the mass and placing it in an old sherry-cask to mellow, as described.

2. The process or method herein described of manufacturing a liquid food (say five gallons) which consists in placing thirty-six new-laid eggs in their shells in a receptacle and covering said eggs with the peel of thirty-six lemons and the juice of seventy-two lemons, placing on the lemon peel thirty-six more new-laid eggs and spreading over same the juice of twelve oranges and two ounces of salt to assist in dissolving the egg-shells, hermetically sealing the receptacle and keeping same closed for about seven days to allow the mass to become gelatinized by the action of the fruit and salt; adding to this mass two and one-half pounds of castor sugar; boiling twenty-five pounds each of beef, mutton, rabbit and chicken until reduced to about two ounces per pound and then well admixing same with the gelatinous body; adding thereto one pint of crushed cereals, three pints of cream, three pints of boiling milk, one-half pound of honey and one-half gallon of cognac; filtering the mass and placing same in an old sherry-cask to mellow for about four weeks, substantially as set forth.

605,191. PUZZLE. EDGAR A. SHIELDS, New York, N. Y. Filed Sept. 15, 1897. Serial No. 651,737. (No model.)

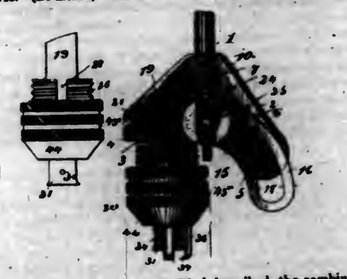
Claim.—1. A puzzle, comprising a box or casing composed of a bottom and vertical side walls, said box or casing being provided interiorly with an angular raised body portion having upon one side angular extensions which project first toward the end walls of the box or casing, and then toward one of the side walls, and an extension upon the other side which is connected with the other side wall, the interior of said box or casing being also provided with detached angular vertical walls partially inclosed by said angular extensions between which is a rectangular space having side openings, and with four sets of bodies or figures, three sets of which are equal in number and each designated from the other by coloring or otherwise, and the other set being also designated from the first three by coloring or otherwise, said box or casing being also provided with one vacant space, substantially as described.

2. A puzzle, comprising a box or casing composed of a bottom and vertical side walls, said box or casing being provided interiorly with an angular raised body portion having upon one side angular extensions which project first toward the end walls of the box or casing, and then toward one of the side walls, and an extension upon the other side which is connected with the other side wall, the interior of said box or casing being also provided with detached angular vertical walls partially inclosed by said angular extensions between which is a rectangular space having side openings, and with four sets of bodies or figures, three sets of which are equal in number and each designated from the other by coloring or otherwise, and the other set being also designated from the first three by coloring or otherwise, said box or casing being also provided with one vacant space, and in each corner thereof with angular detached raised bodies or portions, substantially as described.

605,192. TALKING WATCH OR CLOCK. CASIMIR BYAR, Geneva, Switzerland, assignor to Joseph A. Vincent, Philadelphia, Pa. Filed Aug. 24, 1897. Serial No. 649,288. (No model.) Patented in Switzerland Feb. 21, 1892, No. 4,918.

Claim.—1. In combination with the mechanism of a watch or clock, a sound-reproducing machine comprising a record-disk, means for rotating the same, a diaphragm, a stylus-lever provided with a stylus adapted to the record and to said diaphragm, a cam driven by the watch mechanism adapted to move the stylus and stylus-lever across the record, and means as shown for moving the record-disk into and out of engagement with the stylus.

2. In combination with the watch or clock mechanism, a record-disk, means as shown for rotating the same, a stylus-lever provided with a stylus adapted to the record-disk, a diaphragm acted upon by the stylus-lever, a cam driven by suitable gearing from the minute-hand shaft, said cam being arranged to move the stylus and its lever across the face of the record-disk, and means as shown and described for moving the record-disk into and out of engagement with the stylus.



3. In combination with a clock or watch, a record-disk mounted upon a central shaft rotated by spring means through a train of gearing, a stylus-lever provided with a stylus adapted to traverse concentric rings upon the record-disk, a diaphragm adapted to be acted upon by the stylus-lever, means as shown and described to move the record-disk into and out of engagement with the stylus, a cam controlled by the minute-hand shaft through the medium of gearing for conveying the stylus across the face of the record-disk; means as shown to convey the stylus into and out of engagement with said cam, and a pawl adapted to a spur-wheel carrying said cam to determine the position of the stylus with respect to the record.

4. In combination with the clock or watch mechanism a record-disk mounted upon a central shaft, spring mechanism for rotating said shaft, a stylus-lever as shown, provided with a stylus adapted to the record, a diaphragm adapted to be vibrated by the stylus-lever, a cam controlled by the clock or watch mechanism through the medium of the minute-hand shaft, said cam being arranged to carry the stylus-lever and stylus across the face of the record-disk, a spring-actuated lever adapted to move the record-disk into and out of engagement with the stylus and simultaneously move the stylus-lever into and out of engagement with said cam, and a pawl to engage the spur-wheel carrying said cam, for the purpose specified.

5. In combination with the clock or watch mechanism, a record-disk mounted upon a shaft, spring mechanism for rotating said shaft, a stylus-lever as shown, provided with a stylus adapted to the record, a vibrating diaphragm adapted to be acted upon by the stylus-lever, a cam for operating the stylus-lever controlled by the watch mechanism, through the medium of the minute-hand shaft and gearing, and a lever adapted to move the record-disk into and out of engagement with the stylus and simultaneously move the stylus into and out of engagement with said cam.

6. In combination with the clock or watch mechanism, a record-disk mounted upon a central shaft, spring mechanism for rotating said shaft, a stylus-lever as shown, provided with a stylus adapted to the record, a diaphragm in contact with the stylus-lever, a cam for operating the stylus-lever controlled by the watch mechanism through the medium of the minute-hand shaft and gearing; a lever adapted to move the record-disk into and out of engagement with the stylus and simultaneously move the stylus-lever into and out of engagement with said cam, and a winding-stem provided with mechanism as shown so as to be capable of winding the spring of the watch mechanism when turned in one direction, and the spring controlling the record-disk when turned in the opposite direction.

605,193. MACHINE FOR GRINDING AND POLISHING DIAMONDS. LEOPOLD H. STERN and THOMAS W. G. COOK, New York, N. Y.; said Cook assignor to said Stern. Filed Aug. 27, 1897. Serial No. 649,713. (No model.) Patented in Belgium Nov. 30, 1897, No. 131,964.

Claim.—1. In a device of the kind described, the combination of the supporting-rod 1, the stationary dop-section secured thereto, and having a segmental recess in its lower edge, a movable dop-section, a segmental plate provided with a segmental slot forming part of the movable dop section, means for securing the plate and stationary dop-section together, and a chuck having a plurality of independently-movable gripping-fingers movable in the direction of their length, extending radially from said plate, substantially as described.

2. In a device of the class described, the combination with the rod 1, the dop-section 2 secured to the rod, a segmental recess formed in the lower edge of said section, a plate having an upper edge coincident with said recess, a concentric slot, and a solid projection opposite the slot, a set-screw passing through the slot and into said section, and a chuck with movable holding-fingers extending from said projection, substantially as described.

3. The combination, in a clutch, of a threaded stem, longitudinal grooves formed in said stem, the cap movable on the stem, a plurality of movable gripping-fingers maintained in said grooves and moved by said cap, said fingers projecting outwardly from said cap, each being independently movable in the groove in the direction of their lengths, and a spring held by the stem and bearing against each of the fingers, substantially as described.

4. The combination, in a clutch, of a threaded stem, a plug having a seat rotatably secured in the end of the stem, a cap on the stem and longitudinally-movable gripping-fingers adapted to be moved toward said seat by said cap, substantially as described.

5. The combination, in a clutch, of a threaded stem, longitudinal grooves formed in said stem, a plug rotatably secured in a recess in the end of the stem, said plug having a seat formed in its outer end, a cap on the stem, and longitudinally-movable gripping-fingers in the grooves having ends extending beyond the end of the plug, and adapted to be bodily moved in said grooves in the direction of their length by said cap, substantially as described.

6. The combination, in a clutch, of a threaded stem, longitudinal grooves formed in said stem, a cap movable on the stem, a plurality of gripping-fingers, each being independently movable in said grooves in the direction of their lengths, and springs interposed between one side of the groove and the opposing side of the finger for pressing said fingers against the cap, substantially as described.

7. The combination in a clutch, of the grooved stem, a cap movable thereon, of a plurality of gripping-fingers held between the cap and stem and each capable of an independent sliding movement in the grooves in the direction of their lengths, the stem being interposed between each of said fingers and separating them from each other, and a spring held by the stem and bearing against each of said fingers, substantially as described.

8. The combination, in a chuck, of a grooved stem, a cap movable thereon, the stem extending through the cap, of one or more gripping-fingers held in said groove between the stem and cap, said finger being movable in the direction of its length independent of the cap and bearing against the cap at two points, and a seat secured to the stem exterior of the cap, the point of the finger being adapted to bear against said seat, substantially as described.

9. The combination in a chuck, of a stem having solid center and a longitudinal groove formed between the exterior of the stem and said center a cap movable on the stem over the groove, of a sliding gripping-finger maintained in said groove between the stem and cap, and a spring secured to the stem, loosely engaging the inner side of the finger, and adapted to press it against said cap, substantially as described.

10. The combination with the grooved and threaded stem, of the threaded cap movable on the exterior of said stem, a gripping-finger in said groove, a spring secured to the stem and interposed between the stem and inner side of the finger, a seat formed on the stem and projecting out beyond the cap, the finger extending beyond said seat, a contracted head on the cap, and a shoulder on the outer side of the finger between its ends engaging said head, substantially as described.

11. The combination with the grooved stem, of the cap movable on said stem, a gripping-finger in said stem-groove, said finger having a longitudinal groove facing the stem and an exterior shoulder engaging the cap, and a spring secured to the stem and resting in the groove in the finger between it and the stem, substantially as described.

12. In a clutch, the combination with the stem, of the cap movable on the stem, a groove formed in said stem, a gripping-finger having a groove adjacent said stem and a shoulder on the opposite edge, a rounded shoulder on the end of the cap engaging the shoulder on the finger, and a spring on the stem lying in the groove in the finger, substantially as described.

13. The combination with the grooved stem, of the cap movable on the stem over the groove, a spring secured to the stem at one end within the groove, its free end projecting outwardly therefrom, a grooved gripping-finger engaging the said spring and movable lengthwise thereon, a shoulder on the finger engaging a shoulder on the cap, and an inclined shoulder at the inner end of the finger adjacent the stem, substantially as described.

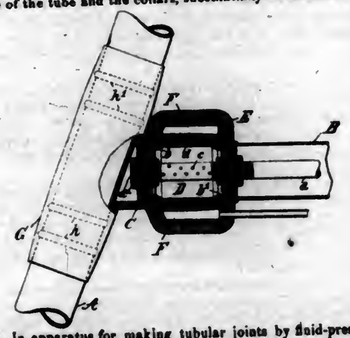
14. The combination with the dop-section 2 having the head 10, of a transverse aperture 9 formed in the head and extending partially therethrough, a threaded aperture 11 formed in the head alining with the aperture 9, a screw having a threaded stem 12 movable in the aperture 11 and adapted to enter the aperture 9, a plug movable in the aperture 9, said plug having a transverse aperture 8, said head 10 having a roof 14 and a crown-piece 6, alining apertures 1^a, 2^a in the crown-piece and roof, and a rod 1 passing through the apertures 1^a, 2^a and 8, the stem 12 abutting against the plug 7, substantially as described.

605,194. ELECTRIC TRANSFORMER. JOHN J. BELLHAM and CHARLES T. RITTENHOUSE, New York, N. Y. Filed June 30, 1897. Serial No. 642,573. (No model.)

Claim.—1. The combination in a transformer, of a ferromagnetic field built up of integral plates so mortised that when the plates are properly assembled the core of the magnetic field will be approximately circular in cross-section, substantially as set forth.

2. The combination in a transformer, of a ferromagnetic field, composed of mortised plates, a divided spool or spools interlinking with the magnetic field, and means for causing the spool or spools to revolve, substantially as set forth.

3. The combination in a transformer, of a ferromagnetic field, a spool or spools interlinking with such field and rollers for supporting the said spool or spools and for causing them to revolve about the core or cores of the magnetic field, substantially as set forth.

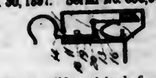


4. The combination in a transformer, of a ferromagnetic field of integral plates each having a mortise through it and a sectional or divided spool or spools interlinking with the ferromagnetic field and primary and secondary wires wound upon said spool or spools by rotating said spool or spools around the core or cores of said ferromagnetic field, substantially as set forth.

5. The combination in a transformer, of a ferromagnetic field built up of plates, and a sectional or divided spool or spools interlinking with the ferromagnetic field and the winding of wire around the core or cores of said ferromagnetic field by the turning of said spool or spools on the core or cores, substantially as set forth.

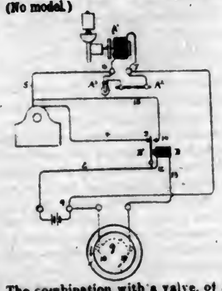
6. The combination in a transformer of a ferromagnetic field built up of plates, a sectional or divided spool or spools interlinking with the core and rollers for supporting the spool while being rotated, substantially as set forth.

605,195. TOOL FOR MAKING JOINTS. JOHN BIRTWELL, Manchester, England. Filed Aug. 20, 1897. Serial No. 649,644. (No model.) Patented in England Mar. 20, 1897, No. 7,067.



Claim.—1. In apparatus for making tubular joints by fluid-pressure, a tool for applying such pressure to a short portion of a tube, comprising a pipe having a perforated portion, a collar at each end of said perforated portion, said collars being smaller in diameter than the tube, and means for making fluid-tight joints between the inner surface of the tube and the collars, substantially as described.

2. In apparatus for making tubular joints by fluid-pressure, a tool for applying such pressure to a short section of a tube, comprising a pipe having a perforated portion, and a flexible water-tight tube, surrounding said portion and adapted to enter the joint, substantially as described.



3. An apparatus for making tubular joints, consisting of an internal tool D comprising a perforated pipe *a* carrying two packed collars and closed at one end *a'*, and an external tool E comprising an annular shell containing the closed annular pipe F of flexible material, and means for conveying fluid-pressure into the pipes *a* and F.

605,196. COMBINATION SASH LOCK AND LIFT. IRA W. BROWN, New York, N. Y., assignor of one-half to Robert Latta, same place. Filed Oct. 30, 1897. Serial No. 656,947. (No model.)

Claim.—A combination lift and lock for a window-sash consisting of a case adapted to be secured to the sash-stile, a bell-crank lever fulcrumed in said case and having one of its arms depending from the fulcruming-point, the free end of said arm being hooked and projecting from said case, a detachable V-shaped spring arranged between said arm of the lever and the wall of the case, a vertically-movable lift arranged in said case and projecting therefrom, the inner end of said lift being hooked and operatively engaging the other of said lever-arms, lugs 18 and 20 situated on the side walls of said case in contiguity to said lift and upon opposite sides thereof, the under faces of said lugs 18 being beveled, beveled lugs 19 arranged on said lift and adapted to wipe on the lugs 18, and a keeper adapted to be engaged by said hooked arm of the lever and secured to the stile of the window-frame, substantially as described.

605,197. ELECTRICAL VALVE-CONTROLLING DEVICE. ARTHUR E. COLGATE, New York, N. Y., assignor to George J. Schoeffel, Brooklyn, N. Y. Filed May 28, 1896. Renewed Apr. 1, 1898. Serial No. 676,136. (No model.)

Claim.—1. The combination with a valve, of a magnet for controlling the same, a circuit extending thereto, an automatic circuit-controller for periodically opening and closing said circuit, and a single hand-operated switch for controlling the operation of the valve at will and also for controlling the connection of the automatic controller with the valve-magnet circuit, substantially as set forth.

2. The combination with a valve, of a magnet for controlling the same, a circuit extending thereto, an automatic circuit-controller for periodically opening and closing said circuit, a magnet for cutting said automatic controller out of circuit, and a single hand-operated switch for controlling the operation of the valve at will and also for controlling the operation of said last-named magnet to connect or disconnect the automatic controller in circuit, substantially as set forth.

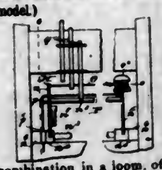
3. The combination with a valve, of a magnet for controlling the same, a circuit extending thereto, an automatic circuit-controller for periodically closing said circuit, and a hand-switch having three contacts and a contact-plate adapted to bridge one pair of said contacts to place said automatic controller in the magnet-circuit to periodically open and close said circuit and to bridge another pair of said contacts to close the magnet-circuit at will, and which contact-plate assumes intermediate positions at which both the automatic controller is cut out of circuit and the magnet-circuit is opened, substantially as set forth.

4. In a weatherproof electrical switch, the combination with a cylindrical and practically water-tight casing, of a set of contacts within the casing carried by a base of insulation, a rotating switch-plate adapted to make contact with said set of contacts, a spindle projecting through the casing for rotating said switch-plate, said plate and set of contacts being adapted to move relatively to each other in a direction lengthwise of the spindle, a hood on said spindle extending over the top of the switch-casing, and a handle for rotating the spindle, substantially as set forth.

5. In a weatherproof electrical switch, the combination with a cylindrical and practically water-tight casing, of a set of contacts within the casing carried by a base of insulation, a rotating switch-plate adapted to make contact with said set of contacts, a spindle projecting through the casing for rotating said switch-plate, said plate and set of contacts being adapted to move relatively to each other in a direction lengthwise of the spindle, a hood on said spindle extending over the top of the switch-casing, a handle for rotating the spindle, and means cooperating with said hood for holding the spindle in its various positions, substantially as set forth.

6. In a weatherproof electrical switch, the combination with a practically water-tight casing, of a series of contacts within said casing carried by a stationary base of insulation, a rotating switch-plate adapted to make contact with said series of contacts, a spindle projecting through the casing for rotating said switch-plate, said switch-plate and said series of contacts being adapted to move relatively to each other in a direction lengthwise of the spindle in addition to the relative movement of rotation, and an operating-handle for said spindle, substantially as set forth.

7. In an electrical switch, the combination with a stationary base of insulation carrying a series of spring-seated contacts, of a rotating switch-plate adapted to make contact with said series of contacts, a spindle for rotating said switch-plate, said series of contacts being held in intimate contact with said switch-plate by the springs upon which they are seated, sockets carried by said stationary base of insulation, contact-posts adapted to enter said sockets, said sockets and contact-posts being arranged to permit slight movement toward and away from each other without breaking contact, and an operating-handle for said spindle, substantially as set forth.



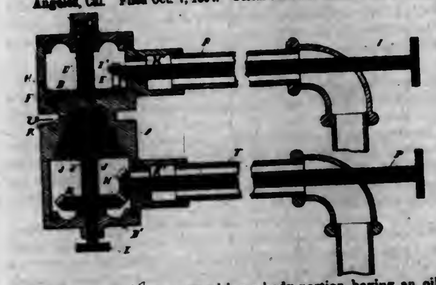
605,198. SAND-BOARD. LILIAN M. ELLIOT, New York, N. Y. Filed May 27, 1897. Serial No. 638,344. (No model.)

Claim.—As an educational device, a sand-board A, adapted to contain sand and provided with a backing *a*, a surrounding flange *a'* extended from the backing, straps B secured to the rear edge, straps B adapted to be looped into straps C and attached to the wall, a recep-

tacle a^2, a flexible binding E on said flange, adapted to prevent the escape of the sand, a cover, F, hinged to said board and means for supporting the board, comprising swinging brackets, H, attached to a support and adapted to permit the device to rest between them against the wall, substantially as shown and described.

605,199. SLACK-ALARM AND STOP-MOTION FOR LOOMS. JOSIAH HARRIMAN and JOHN HARRIMAN, Lowell, Mass.; said John Harriman assignor to said Josiah Harriman. Filed Feb. 7, 1896. Serial No. 578,354. (No model.)

Claim.—1. The combination in a loom, of a vibrator operated by a moving part of the loom, drops, each adapted to be supported by a warp of normal tension, and an audible signal supported on said vibrator, and a cord carried by said vibrator and connected to said signal and arranged to strike and to be pulled by a fallen drop, as and for the purpose specified.



2. The combination in a loom, of the lay, a vibrator, operated by the movement of said lay, drops, each adapted to be supported by a warp of normal tension, and an audible signal supported on said vibrator, and a cord carried by said vibrator and connected to said signal and arranged to strike and to be pulled by a fallen drop, as and for the purpose specified.

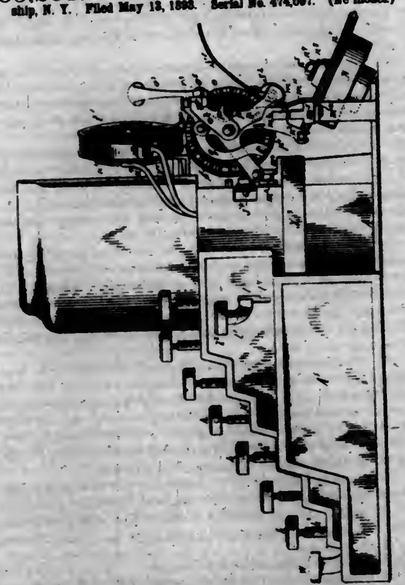
3. The combination in a loom, of a vibrator operated by a moving part of the loom, a cord, stretched across said vibrator, a mechanical buzz-bell, supported on said vibrator and adapted to be operated by the pulling of said cord, and drops, each normally supported by a warp-thread and adapted upon the slacking of said warp-thread, to fall in the path of said cord and to pull the same, as and for the purpose specified.

4. The combination in a loom, of a vibrator, operated by a moving part of said loom, a cord carried thereby, an audible signal operated by the pulling of said cord, another cord carried by said vibrator, below said first-named cord, the shipping-lever, intermediate mechanism connected to said second-named cord and engaging said shipping-lever and operated by the pulling of said second-named cord, to disengage said shipping-lever, and drop-wires, each adapted to be supported by a warp of normal tension and to fall and engage said first-named cord upon the slacking of such warp and to engage said second-named cord upon the breaking of such warp, as and for the purpose specified.

5. The combination of a main shaft, a loose pulley, a fast pulley, a shipping-lever, a shipping-rod, to move said shipping-lever, a spring, to operate said rod in one direction, to move the belt from said fast pulley to said loose pulley, a collar fast on said shipping-rod, a bolt, normally engaging said collar, a lever, engaging said bolt to draw the same out of engagement with said collar, the lay, another lever, pivoted on said lay, a vibrator, operated by the movement of said lay, a cord connecting said vibrator and said last-named lever, and drops, each adapted to be supported by a warp-thread of normal tension and when unsupported to engage said cord and to raise said last-named lever into a position to strike said bolt-engaging lever and disengage said bolt from said collar, as and for the purpose specified.

605,200. HYDROCARBON-BURNER. CHARLES B. KITTLE, Los Angeles, Cal. Filed Oct. 7, 1897. Serial No. 654,484. (No model.)

Claim.—1. A burner comprising a body portion having an oil-chamber in its upper part, a steam-chamber in its lower part, a vertical oil-discharge port, and a horizontal steam-discharge port, the steam-discharge port discharging across the axis of the oil-discharge port, in combination with a valve having a spiral at its top and arranged to govern the steam-discharge port, substantially as described.



2. In a hydrocarbon-burner, the combination with the frame, A, having main discharge-port, U, a horizontal steam-discharge port, K, and vertical oil-discharge port, F, leading to discharge-port, U, and arranged to cause the steam and oil discharged therefrom to intermingle at the main discharge-port, the frame having a chamber in the upper part thereof adapted to receive an oil-valve, and a chamber in the lower part adapted to receive a steam-valve; a rotary oil-valve, D, having oil-passages, H, located in the upper chamber; and rotary steam-valve, J, having steam-passages, J', and having spiral top, located in the lower chamber, the said valves rotatively operated by stems, I, and P, respectively having means therefor substantially as shown and described.

3. A burner, comprising a body portion having an oil-chamber in its upper part; a steam-chamber in its lower part; a vertical oil-discharge port and a horizontal steam-discharge port, the oil-discharge port discharging across the axis of the steam-discharge port, in combination with the rotary valve D, being in the form of a disk having passages therethrough adapted to register with the oil-discharge port and thereby govern the discharge of oil, substantially as shown and described.

4. A burner, comprising a body portion having an oil-chamber in its upper part; a steam-chamber in its lower part; a vertical oil-discharge port; and a horizontal steam-discharge port, both discharging into a main discharge-port, adapted to mingle the oil and steam at the mouth of the main discharge-port, in combination with a conical-shaped valve being spiral at the top and having passages therethrough and arranged to govern the steam-discharge port, substantially as shown and described.

5. In a burner, comprising a body portion having oil and steam chambers; oil and steam discharge ports, the cone-shaped valve, J, having a spiral top, and having passages, J' J', therethrough for the passage of steam and arranged to govern the steam-discharge port, substantially as shown and described.

605,201. TYPE-WRITING MACHINE. HENRY C. LATTA, Friendship, N. Y. Filed May 13, 1893. Serial No. 474,097. (No model.)

Claim.—1. The combination with the platen, of two sets of alternating type-bars having thin body portions and thickened pivot portions, and a supporting-segment having guide-slots, the inner portions of which are narrow and receive the body portions of the type-bars and the outer portions of which are wider and receive the thick pivot portions of the bars, substantially as set forth.

2. The combination with the platen, and a supporting-segment provided with radial guide-slots, having narrow inner portions and

wide outer portions, of separate pivot-wires arranged one in advance of the other and intersecting said guide-slots, and independent groups of type-bars mounted on said pivot-wires respectively, each type-bar having a thin body portion and a thickened pivot portion and the bars of one group alternating with those of the other group, substantially as set forth.

3. The combination with the type-bars and their support, of a pivot-wire passing through openings in the hubs of the type-bars and in said support, capable of being shifted lengthwise in said support for bringing different portions thereof within the pivot-holes of the type-bars, and having screw-threaded ends, and adjusting-nuts applied to the threaded ends of said wire and bearing against said support, substantially as set forth.

4. The combination with the platen and the slotted supporting-segment, of independent pivot-wires arranged one in advance of the other and intersecting said slots, and independent sets of type-bars pivoted in said slots and having crank-arms, the form as one set of type-bars having notches which engage over the pivot-wire of the adjacent set, substantially as set forth.

5. The combination with the frame of the machine and a type-bar, of a key-lever having angular end portions which are pivoted to the frame, the intermediate body portion of the lever being offset with reference to said end portions throughout its length and a connection extending from said type-bar to the body portion of the key-lever, substantially as set forth.

6. The combination with the frame of the machine and a type-bar, of a key-lever having angular or offset end portions which are pivoted to the frame, the intermediate body portion of the lever being offset with reference to said end portions throughout its length, a key connected with the offset body portion of said lever and a connection extending from the body portion of said lever to said type-bar, substantially as set forth.

7. In a type-writing machine, the combination with the key-lever, of a split tubular shank attached to the lever and having an internal screw-thread and a key having a screw-threaded stem engaging with the internal thread of said split shank, substantially as set forth.

8. The combination with the platen and the type-bars, of a rebounder normally intercepting the type-bars but allowing the type on the bars to strike the platen, a normally rigid support carrying said rebounder and capable of vertical movement, whereby the rebounder may be raised above its normal position, and a retaining device whereby the rebounder is held in said abnormal position, substantially as set forth.

9. The combination with the platen and its carriage, the type-bars and the key-levers, of a vertically-movable rebounder intercepting the type-bars and a lifting device whereby the rebounder is automatically elevated when the carriage reaches the end of its movement, substantially as set forth.

10. The combination with the platen and its carriage, the type-bars and the key-levers, of a vertically-movable rebounder intercepting the type-bars, a spring tending to raise the rebounder above its normal height, a catch for holding the rebounder in its normal position, and a releasing device connected with the carriage, whereby said catch is released, substantially as set forth.

11. The combination with the platen and its carriage, the type-bars and their operating-levers, of a horizontal rebounder intecepting the type-bars and having a notched guide-rod, a spring tending to elevate said rebounder, a detent engaging with the notched guide-rod for holding the rebounder in its lowered position, and a trip device arranged on the carriage and adapted to release said detent, substantially as set forth.

12. The combination with the platen and its carriage, the type-bars and the key-levers, of a vertically-movable rebounder intercepting the type bars, an elevating device whereby the rebounder is raised above its normal height when the carriage reaches the end of its movement, and a return device connected with the carriage, whereby the rebounder is automatically depressed upon returning the carriage to its initial position, substantially as set forth.

13. The combination with the platen and its carriage, the type-bars and their operating-levers, of a rebounder intercepting the type-bars and capable of rising above its normal height, means for elevating the rebounder to such abnormal height when the carriage reaches the end of its movement, and a lever for lowering the rebounder to its normal position, substantially as set forth.

14. The combination with the platen-carriage, the type-bars and their operating-levers, of an intercepting device for preventing the type-bars from reaching the platen when the carriage reaches the end of its movement, and a stop connected with said intercepting device, adapted to engage against the carriage and arrest its movement, substantially as set forth.

15. The combination with the platen and its carriage, the type-bars and their operating-levers, of a movable intercepting device arranged in the path of the type-bars and having a guide-rod, and a stop-rod extending rearwardly from said guide-rod, and adapted to arrest the movement of the carriage, means for elevating said intercepting device, a depressing-lever engaging with said guide-rod, and a key-lever connected with said depressing-lever, substantially as set forth.

16. The combination with the platen and its carriage, the type-bars and the key-levers, of a vertically-movable rebounder intercepting the type-bars, an elevating device whereby the rebounder is raised above its normal height when the carriage reaches the end of its forward movement, a locking device for holding the rebounder in its depressed position, a trip device arranged on the carriage, and a pivoted inclined tooth connected with the rebounder and arranged in the path of said trip device when the rebounder is elevated, said tooth yielding in one direction but being rigid in the opposite direction, substantially as set forth.

17. In a type-writing machine, the combination with the platen, of an elastic rebounding device, and type-bars adapted to strike said rebounding device and having impact faces of different areas, whereby the latter offers a correspondingly greater or less resistance to the type-bars, substantially as set forth.

18. In a type-writing machine, the combination with the carriage having a step-by-step feed movement, of a device for shifting the carriage backward, a lever connected with said shifting device for operating the same, and stops which limit the movement of the lever when the carriage is set back either a whole space or half a space, substantially as set forth.

19. In a type-writing machine, the combination with the carriage having a step-by-step feed movement, of a device for shifting the carriage backward, a lever for operating said shifting device and a guide for said lever having a stop for limiting the movement of the carriage when the carriage is set back half a letter-space, and a second stop for limiting the movement of said lever when the carriage is set back a whole space, substantially as set forth.

20. The combination with the carriage having a ratchet-bar, of a set back pawl adapted to engage with said ratchet-bar, and capable of moving lengthwise of said bar, and a shifting-lever interlocking with said pawl, substantially as set forth.

21. The combination with the carriage having a ratchet-bar, of a set-back pawl adapted to engage with said ratchet-bar, and capable of moving lengthwise of said bar, a shifting-lever interlocking with said pawl, and a key-lever connected with said shifting-lever, substantially as set forth.

22. The combination with the carriage having a ratchet-bar, of a set-back pawl adapted to engage with said bar and capable of sliding lengthwise thereof, a shifting-lever interlocking with said pawl for moving it backward, and a spring for retracting the pawl, substantially as set forth.

23. The combination with the carriage having a ratchet-bar, of a set-back pawl adapted to engage with said bar and capable of sliding lengthwise thereof, a shifting-lever having a spur interlocking with said pawl and a cam whereby the pawl is moved into engagement with said rack-bar, a spring for retracting the pawl, and a key-lever connected with said shifting-lever, substantially as set forth.

24. In a type-writing machine, the combination with the platen and the ribbon-spools and their intermittent feed mechanism, of a reversing-bar for alternating the feed of the ribbon from one spool to the other and a ribbon-guide mounted upon said bar opposite the printing-point, over which the ribbon passes, whereby both edge portions of the ribbon are brought over the printing-poiat by the movement of the reversing-bar, substantially as set forth.

25. In a type-writing machine, the combination with the platen, the type-bars and the universal bar or frame, of ribbon-spools arranged on opposite sides of the printing-point, actuating-pawls connected with the universal bar or frame and adapted to engage alternately with the ribbon-spools, a sliding reversing-bar controlling said pawls and having loops or apertures, and shifting-arms adapted to bear against the periphery of the ribbon-coils upon said spools and passing through the loops of the reversing-bar, substantially as set forth.

26. In a type-writing machine, the combination with the platen, the type-bars and the universal bar or frame, of ribbon-spools arranged on opposite sides of the printing-point, actuating-pawls connected with the universal bar or frame and adapted to engage alternately with the ribbon-spools, a sliding reversing-bar controlling said pawls and having loops or apertures, and flexible shifting-arms adapted to bear with their free portions against the ribbon-coils on said spools and passing through the loops or apertures of the reversing-bar, substantially as set forth.

27. In a type-writing machine, the combination with the platen, the type-bars and the universal bar or frame, of ribbon-spools arranged on opposite sides of the printing-point, actuating-pawls connected with the universal bar or frame and adapted to engage alternately with the ribbon spools, a sliding reversing-bar controlling said pawls and operated by the enlargement of the ribbon-coils of the spools,

and a yielding catch for holding said reversing-bar in place, substantially as set forth.

28. In a type-writing machine, the combination with the carriage and the rotary platen, of a shaft passing axially through the platen and capable of turning in the same, a device for turning said shaft, arranged at one end thereof and a shifting device arranged at the opposite end of said shaft and engaging with the platen, substantially as set forth.

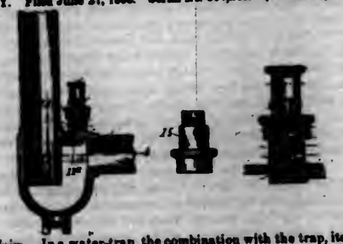
29. In a type-writing machine, the combination with the carriage and the platen, of an axle for the platen passing loosely through the latter, journaled on the carriage, and provided at both ends with cranks or levers for turning it, and a connection whereby the movement of the axle is transmitted to the platen, substantially as set forth.

30. In a type-writing machine, the combination with the carriage and the platen provided at one end with a toothed rim, of an axle, passing loosely through the platen and having at one end a device for turning it, and a radial arm attached to the other end of the axle and carrying an actuating-pawl which engages with the toothed rim of the platen, substantially as set forth.

31. In a type-writing machine, the combination with the carriage and the rotary platen, of a shaft passing axially through the platen and capable of turning backwardly in the same, a connection whereby the platen is caused to turn forwardly with the axle, and a spring whereby the axle is returned to its normal position, substantially as set forth.

32. In a type-writing machine, the combination with the carriage and the platen provided at one end with a toothed rim, of an axle passing loosely through the platen and having at one end a device for turning it, a radial arm attached to the other end of the axle and carrying an actuating-pawl which engages with the toothed rim of the platen, and a spiral return-spring secured at one end to the axle of the platen and at its other end to the carriage, substantially as set forth.

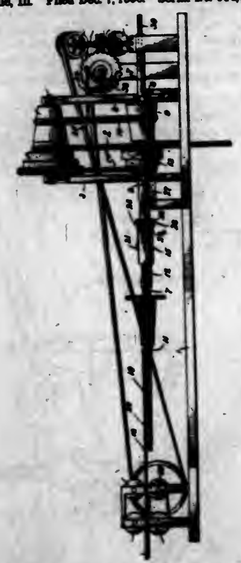
33. The combination with the carriage and the platen, of an axle passing loosely through the platen and journaled on the carriage, a crank arranged at one end of said axle, a shifting device attached to the other end of the axle and engaging with the platen, a detent device for preventing backward movement of the platen and a spring for returning the platen-axle to its normal position, substantially as set forth.



34. The combination with the carriage-frame having a number of locking recesses, of the platen and its shifting device, and an elastic stop-arm pivoted concentrically with the platen and having a projection adapted to engage in one of said locking-recesses, substantially as set forth.

35. The combination with the carriage and the platen, of a rotary scale-bar of round cross-section flattened on one side and having a spiral screw-thread engaging in a threaded bearing on the carriage, and a lever pivoted to the carriage and adapted to bear against one end of said scale-bar, substantially as set forth.

36. The combination with the carriage and the platen, of a rotary scale-bar of round cross-section flattened on one side and having a spiral screw-thread engaging in a threaded bearing on the carriage, a lever pivoted to the carriage and adapted to bear against one end of said scale-bar, and a spring for returning the bar to its normal position, substantially as set forth.



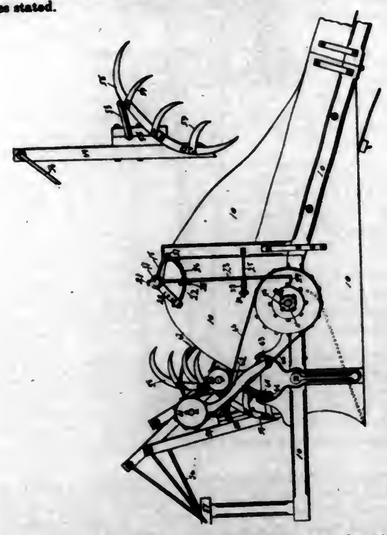
37. The combination with the main frame of the machine provided with a U-shaped slot forming a projecting tongue, of a pair of key-levers, and a duplex elevating-spring having arms bearing against said key-levers respectively and connected at their rear ends by a bar interlocking with said tongue and provided in front of said bar with a stop bearing against the main frame, whereby said connecting-bar is locked in place, substantially as set forth.

605,202. TRAP FOR SINKS, &c. LEOPOLD MULLENHOFF, Buffalo, N. Y. Filed June 27, 1896. Serial No. 597,205. (No model.)

Claim.—In a water-trap, the combination with the trap, its valve and valve-chamber, of a screw-cap for closing the top opening in said valve-chamber, and having a reduced portion extending vertically from the top thereof, tubular portions adapted to seat and be seated upon the reduced portion, and provided with a transverse slot, and a circular opening and a cap provided with a pin fitting in said slot and an opening adapted to register with the opening in the tubular portion, when the cap is rotated to the proper position upon said tubular portion, as set forth.

605,208. WOOL-SPINNING MACHINE. WILLIAM W. HEW, Morrellville, Ill. Filed Dec. 7, 1896. Serial No. 614,903. (No model.)

Claim.—1. The bobbin-shaft having provision at one end for the attachment of a bobbin and provided at or near its opposite end with a worm-wheel, in combination with a flier having a feather-and-spline engagement with a hollow shaft which surrounds the bobbin-shaft and is driven independently thereof, a spur gear-wheel meshing with and driven by said worm-wheel, and connections between said spur-gear and the flier, whereby said flier is reciprocated as the bobbin-shaft is rotated, substantially as described.



2. The bobbin-shaft having provision at one end for the attachment of a bobbin and provided at or near its opposite end with a worm-wheel, means for actuating said bobbin-shaft, a hollow shaft surrounding said bobbin-shaft, actuating means therefor, a flier revolving around the bobbin and having a feather-and-spline connection with said hollow shaft, a spur gear-wheel meshing with and driven by said worm-wheel, a shipping-fork engaging said flier, and a pitman or connecting-rod interposed between said spur gear-wheel and shipping-fork, whereby the flier is reciprocated as the bobbin is rotated, substantially as described.

3. The bobbin-shaft having provision at one end for the attachment of the bobbin, and provided with a worm-wheel in combination with means for actuating said shaft, a hollow shaft surrounding said bobbin-shaft, a flier having a feather-and-spline connection with said hollow shaft, means for actuating said shaft, a shipping-fork engaging said flier at one end and connected at its opposite end to a slide-block, a longitudinally-grooved guide in which said block reciprocates, a spur gear-wheel meshing with and actuated by said worm-wheel, and a connecting-rod interposed between said slide-block and spur gear-wheel, substantially as described.

605,204. SELF-FEEDER FOR THRESHING-MACHINES. GEORGE W. FARNESS, Newton, Iowa, assignor of one-third to Fred Sims Rich, same place. Filed May 7, 1897. Serial No. 635,490. (No model.)

Claim.—1. In a self-feeder for threshing-machines, a device for automatically stopping the motion of the endless conveyer when an excessive quantity of grain is found thereon, comprising in combination, a self-feeder frame, an endless conveyer thereon, trip-bars arranged above the conveyer to be engaged by an excessive quantity of grain upon the conveyer, a detent-arm connected with the said trip-bars to be moved in unison therewith, yielding pressure devices

for returning the said detent-arm to its normal position after it has been moved rearwardly by the motion imparted to the trip-bars, a sprocket-wheel loosely mounted on the shaft of the endless conveyer, a series of rollers on one side of said sprocket-wheel arranged at points equidistant from its center, a wheel keyed to the same shaft of the endless conveyer, peripheral teeth thereon to be engaged by said detent-arm when the detent-arm is moved rearwardly, a trip device pivoted to the face of the said keyed wheel and capable of moving outwardly in the path of the aforesaid rollers on the loosely-mounted wheel or of moving inwardly so as not to engage said rollers, a spring for normally holding said trip device outwardly to intercept the path of the said rollers, and means whereby the said trip device may be thrown inwardly so as to not enter the path of the said rollers when the said detent-arm engages the teeth on the periphery of the said keyed wheel, substantially as and for the purposes stated.

2. In a self-feeder for threshing-machines, a device for automatically throwing the endless conveyer thereof in and out of gear, comprising in combination, a self-feeder frame, an endless conveyer thereon, trip-bars pivotally mounted above the endless conveyer to be engaged by an excessive quantity of grain on the conveyer and moved upwardly, a detent-bar connected with the said trip-bars, yielding pressure devices for normally holding the said detent-bar to its forward limit, a sprocket-wheel loosely mounted on the shaft of the endless conveyer, a number of rollers on its outer face at points equidistant from its center, a disk keyed to the same conveyer-shaft and having a number of notches in its periphery, a trip device pivoted thereto and having an enlarged head and a pocket, a spring fixed at one end to the said disk and at its other end to the said trip device, a rim rotatably mounted upon the said disk and having peripheral teeth, a series of projections formed on or fixed to the outer surface of the said rim inwardly over the disk and to be capable of entering the said notches in the disk, and a pin on the said rim to enter the pocket of the trip device, all arranged and combined to operate in the manner set forth and for the purposes stated.

3. In a self-feeder for threshing-machines, the combination of a frame, a conveyer, trip-bars positioned above the rear extremity of the conveyer, mechanism connecting with said trip-bars whereby a rearward pressure upon the trip-bars, such as would be caused by an excessive quantity of grain carried by the conveyer, will operate to retard the movement of the conveyer, means for limiting the rearward movement of said trip-bars so that when at the rearward limit of their movement they will engage and positively hold an excessive quantity of grain from passing beyond the conveyer, for the purpose stated.

4. A self-feeder for threshing-machines, comprising in combination, a frame, an endless conveyer thereon, an inclined bottom or pan leading from the rear turn of the conveyer downwardly and rearwardly, a shaft pivotally mounted above the rear turn of the endless conveyer, a series of trip-arms thereon to project downwardly and rearwardly, a detent-bar mounted on the said shaft, an arm fixed to said shaft, a segmental rod fixed to said arm and extended through an opening in the said detent-bar, a yielding pressure device for holding the trip-bars, to their forward limit and for returning them when pressed rearwardly, a sprocket-wheel loosely mounted on the endless conveyer shaft, a disk fixed to the endless conveyer shaft and arranged to be engaged by the said detent-bar, mechanism whereby, when the detent-bar is in engagement with the said disk, the sprocket-wheel and the said disk are disengaged, and when the detent-bar is not in engagement therewith the said disk and sprocket-wheel are connected for rotation, a crank-shaft rotatably mounted in the rear of the said trip-bars, a sprocket-wheel fixed to one end thereof, an adjustable idler pivoted to the machine-frame, a sprocket-chain passed around the idler and around the sprocket on the conveyer-shaft and beneath the sprocket on the crank-shaft, means for adjusting the said idler to take up the slack in the chain, a feed-bar pivoted to each of the cranks of the said crank-shaft, a pair of feed-hooks on each of said feed-bars, and rods pivoted to the upper ends of the said feed-bars and to fixed supports in the rear thereof, all arranged and combined substantially in the manner set forth and for the purposes stated.

605,205. FIFTH-WHEEL FOR RAILWAY-CARS. LEVI R. PERRY and JAMES C. MITCHELL, Lewiston, Me., assignors of three-twentieths to Herbert R. Chase, same place. Filed Sept. 14, 1897. Serial No. 651,613. (No model.)

Claim.—1. A swivel for the purposes set forth, comprising two parts, one having a depending annular flange forming a depressed surface within the same, said surface being provided with a concentric series of concave recesses, and the other part having a central raised portion fitting within the flange; together with balls seated within the recesses of the first-mentioned part to bear upon the raised portion of the last-mentioned part, substantially as shown and described.

2. A swivel for the purposes set forth, comprising two parts having registering central openings to receive a king-bolt or pivot-pin, one of the parts presenting an annular flange forming a depressed surface surrounding the opening, said surface being provided with concave recesses, balls seated within the concave recesses, and a retaining-plate fitting within the flange and having openings through which the balls project slightly beyond said plate; together with the other part having a central raised portion fitting within the flange and presenting a surface provided with a circular groove or runway, substantially as shown and described.

3. A swivel for the purpose set forth, comprising two circular plates, one having a depending annular flange forming a central depressed portion and surrounding web, the depressed portion being provided with a concentric series of concave recesses, bearing-surfaces located in said recesses, balls bearing within the recesses, and a retaining-plate fitting within the flange and having openings through which the balls pass; together with the other plate having a surrounding web and a central raised portion forming a circular shoulder, the upper surface of the raised portion being provided with a circular groove; both of the aforesaid plates having central openings through which passes a king-bolt or pivot-pin, substantially as shown and described.

4. A swivel for the purpose set forth, the combination, of a circular plate having a depending annular shoulder near its outer edge forming a depressed surface surrounding a central opening in the plate, said surface being provided with a concentric series of concave recesses, bearing-posts extending into said recesses centrally, balls seated within the recesses upon the posts, a retaining-plate fitting within the flanges and having openings through which the balls project slightly beyond said plate, and means for holding the retaining-plate in place; together with a circular plate presenting a surrounding web and a central raised portion forming a circular step or shoulder, the upper surface of the raised portion having a circular groove surrounding a central opening in the plate which registers with the central opening in the other plate, the raised portion of the last-mentioned plate fitting within the annular flange of the first-mentioned plate, as herein shown and described.

5. The rub-plates, for the purpose set forth, comprising a member having a series of concave recesses and projecting ears, bearing-posts extending into the center of the concave recesses, a retaining-plate having openings through which the balls project, and means for holding the retaining plate in place; together with a second member having a plain upper surface and projecting ears, as shown and described

605,206. FURNACE. ANDREW PILLATT, Nottingham, England. Filed Aug. 6, 1896. Serial No. 601,912. (No model.) Patented in England July 18, 1896, No. 13,571; in Germany Aug. 20, 1896, No. 87,545; in France Sept. 14, 1896, No. 260,260; in Belgium Nov. 11, 1896, No. 118,268; in Italy Nov. 16, 1896, No. 40,171; in Austria Jan. 11, 1898, No. 46,106, and in Canada Feb. 14, 1898, No. 57,337.

Claim.—1. A grate-bar adapted to be fitted in a furnace with one end communicating with an opening through the bridge-wall leading to the combustion-chamber, and having a longitudinal passage extending to said end and constructed to receive air below the top substantially uniformly throughout its length and deliver it for combustion beyond the fuel-chamber, substantially as specified.

2. The combination of a furnace and a hollow grate-bar with an end bearing adapted to a hollow bearing formed through a bridge-wall and open to receive air from the ash-pit substantially uniformly throughout its length, substantially as specified.

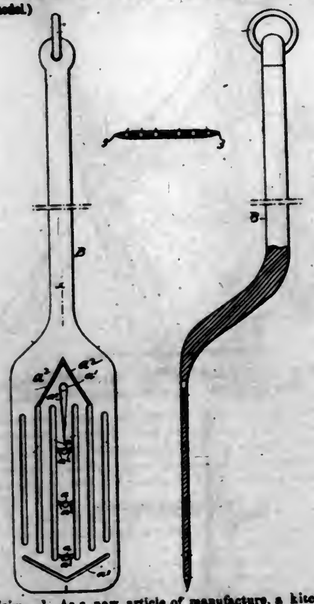
605,207. CLOTHES PIN OR CLAMP. LOGAN B. REESE, Fulton, Ky. Filed Feb. 8, 1897. Serial No. 622,677. (No model.)

Claim.—A metal clothes-pin consisting of a single piece of wire bent into two complete coils each lying in proximity to the other, the free ends of the wire being curved back to points opposite each other and within the plane of the sides of the coils and having their extreme ends formed with loops or eyes lying close to the coils, substantially as described.

605,208. WHEEL-HUB. SOLOMAN A. SEARLS, Buffalo, N. Y. Filed July 16, 1897. Serial No. 644,703. (No model.)

Claim.—1. The combination with the barrel, of a sprocket-wheel mounted on said barrel and provided with an inwardly-projecting annular flange which bears against the end of the barrel, and a bearing-cap connected with the barrel and provided with an outwardly-projecting flange which bears against the outer end of the sprocket-wheel, substantially as set forth.

2. The combination with the barrel provided at one end with serrations, of a sprocket-wheel mounted on said barrel and provided with an internal annular flange having serrations which engage with the serrations of the barrel, and a bearing-cap having a screw connection with the barrel and provided with an external annular flange which bears against the outer end of the sprocket-wheel, substantially as set forth.



3. The combination with the hub-barrel having an opening in its wall, of a locking-washer arranged in the barrel and having an oblong opening which is narrower than said barrel-opening and which coincides therewith, and a spoke-fastening button rotatably seated in said coinciding openings and having an oblong inner portion which is constructed to pass through the oblong opening of the locking-washer when turned in line therewith and which interlocks with the washer when turned out of line with said oblong opening, substantially as set forth.

4. The combination with the hub-barrel provided with openings, of spoke-fastening buttons arranged in said openings and connected with spokes, each of said buttons being provided with a contracted portion forming inwardly and outwardly facing shoulders, and a locking device arranged in said barrel and engaging with said buttons between the shoulders thereof, substantially as set forth.

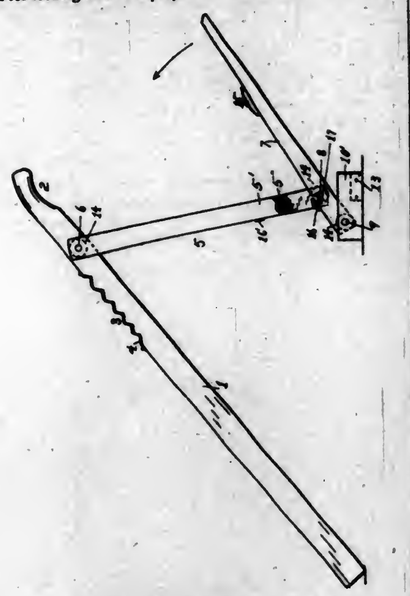
5. The combination with the hub-barrel provided with circular openings, of a locking-ring arranged in said barrel and provided with slots arranged in line with said openings, and spoke-fastening buttons each of which is provided with a circular head which fits into one of said openings, a cross-bar bearing against the inner side of the locking-ring on opposite sides of the adjacent slot and a contracted neck arranged in said slot and connecting the head and cross-piece, substantially as set forth.

6. The combination with the hub-barrel provided with openings, of spoke-fastening buttons arranged in said openings, a locking-ring arranged in the barrel and engaging with the inner ends of the buttons, and a dust-guard consisting of a ring and two outwardly-projecting annular flanges which bear against the inner side of the locking-ring on opposite sides of the buttons, substantially as set forth.

605,209. COMBINED KNIFE AND SCOOP. JAMES A. SWINBURNE, New York, N. Y., assignor of one-half to James A. Cambridge, same place. Filed June 1, 1897. Renewed May 9, 1898. Serial No. 680,232. (No model.)

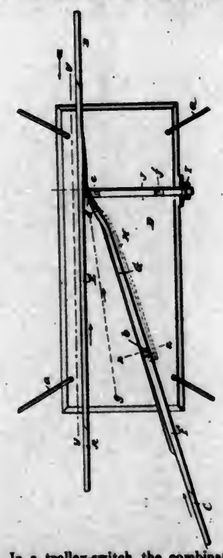
Claim.—1. As a new article of manufacture, a kitchen implement comprising a thin flat metal plate adapted for use as a cutter having parallel longitudinal apertures in the central portion and an angular aperture in one end thereof, grooves on its upper surface leading to the said parallel apertures, a knife-edge surrounding the said plate and a projected handle, substantially as shown and described.

2. As a new article of manufacture, a culinary implement comprising a flat metallic plate having a knife-edge thereon and lateral and longitudinal and central apertures leading therethrough for the escape of drippings, surface grooves on one side communicating with the central and longitudinal apertures and a handle projected from one end, substantially as shown and described.



605,210. LIFTING-JACK. WILLIAM B. TYLER, Aldie, Va., assignor of three-fourths to Hugh B. Hutchison same place, and John A. Hiesl and French E. Randall, Manassas, Va. Filed Dec. 18, 1897. Serial No. 662,500. (No model.)

Claim.—1. In a lifting-jack the combination of levers 1 and 7 and the intermediate prop 5 pivotally connecting the levers, a pivot-pin fixed in the prop, said lever 7 being formed with a slot to receive said pin, and means for removably holding the pin in the slot, substantially as described.

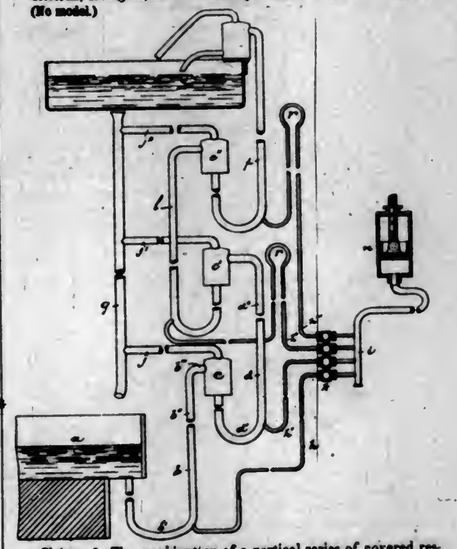


2. In a lifting-jack the combination of base 10, levers 1 and 7 and the intermediate prop 5 pivotally connecting the levers, the lever 7 being adapted to be folded parallel with and contiguous to the prop, and a button carried by lever 7 for securing it in the folded position, substantially as described.

3. In a lifting-jack, base 10, levers 1 and 7, and prop 5 pivotally

connecting the levers, said prop being constructed of two parallel members, said lever 7 being adapted to be turned upward beyond the vertical position and housed between the members of prop 5, and means for locking lever 7 to prop 5.

605,211. TROLLEY-SWITCH. JACOB H. VANAMBLE, Seattle, Wash. Filed Oct. 2, 1897. Serial No. 653,841. (No model.)



Claim.—1. In a trolley-switch, the combination of a suitably-supported switch-plate provided with a keeper, a guide arranged at the under side of the plate, a movable, spring-pressed switch-point arranged at the under side of the switch-plate and normally bearing against the guide, and a latch also arranged at the under side of said plate and connected with the switch-point and adapted to engage the keeper and hold the switch-point away from the guide, substantially as specified.

2. In a trolley-switch, the combination with the main-line and turnout conductors; of a suitably-supported switch-plate having a guide on its under side interposed between the main-line conductors, a guide abutting against the turnout-conductor, and a keeper, a switch-point pivotally connected with and disposed at the under side of the plate, a spring for normally holding said point against the first-named guide of the plate, and a latch-bar loosely connected to the switch-point and resting on the keeper and adapted to engage said keeper, substantially as specified.

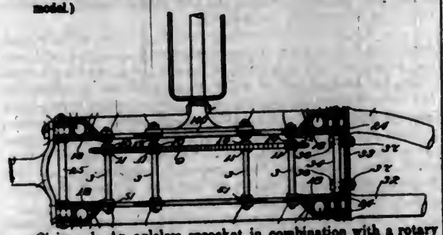
3. In a trolley-switch, the combination with the main-line and turnout conductors; of a suitably-supported switch-plate provided with the slot *e* and having, on its under side, a guide interposed between the main-line conductors, a guide forming the terminal of the turnout-conductor, and a keeper, a switch-point pivotally connected with and disposed at the under side of the plate and having its heel arranged contiguous to the second-named guide of the switch-plate, and a latch also arranged at the under side of said plate and connected with the switch-point and adapted to engage the keeper, and the flat spring H disposed above the switch-plate and connected at one end to the same and having a depending portion at its opposite end loosely arranged in the slot *e* and connected to the switch-point, substantially as specified.

605,212. PNEUMATIC ELEVATING DEVICE FOR LIQUIDS. ANTOINE WARTER, Newark, N. J., assignor of one-half to William L. Glorieux, Irvington, N. J. Filed Sept. 29, 1897. Serial No. 653,432. (No model.)

Claim.—1. The combination of a vertical series of covered reservoirs, connecting-pipes each leading downward from the bottom of a reservoir and being turned upward and entering the reservoir next higher, and compressed-air tubes leading from an air-compressor to each of said connecting-pipes, branch overflow-ducts leading from the tops of the reservoirs and a main overflow-duct connecting with each of said branch ducts, whereby liquid may flow from the filled reservoirs without being elevated, substantially as set forth.

2. The combination of the series of covered tanks or reservoirs *c*, *c'*, *c''*, one elevated above another, the connecting-pipes *b*, *d*, *l*, each leading downward from the bottom of a tank and being turned upward and entering the upper part of the tank next higher, the compressed-air tubes leading into said connecting-pipes at the points where they are turned upward, and escape-ducts leading from the top of each tank to a vertical main duct which communicates at its lower end with the source of supply, the whole forming a closed passage for the liquid from the source of supply to the point of elevation, substantially as set forth.

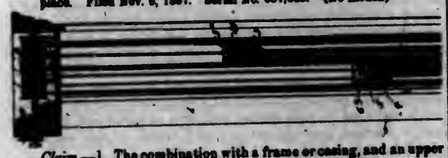
3. In a pneumatic elevating device for liquids, the combination with a series of bent pipes *h*, *d*, *l*, each having long and short arms, the long arm of one communicating with the short arm of the next upper pipe of the series and conducting the liquid thereto, closed enlargements *c*, *c'*, *c''*, being arranged at the connections, the long arms entering at the sides of said enlargements and the short arms extending down from a point at or near the bottom thereof, vent-tubes *j*, *j'*, *j''*



extending from the upper parts of said enlargements to a common vent and drip pipe *g*, extending down to an initial tank or body of fluid to be elevated, and a series of compressed-air pipes *h*, *h'*, *h''*, turned upward at one series of extremities and entering the bases or bottoms of the longer upward extensions of the fluid-elevating pipes *b*, *d*, *l*, and at the other extremities extending into close adjacency where they are provided with cut-off valves, a common compressed-air pipe connecting with each of said pipes *h*, *h'*, *h''*, and with a pump *n*, the upper pipes of the series of compressed-air pipes being bowed or bent double to extend above the points of egress from the fluid-elevating pipe into the said enlargements, substantially as set forth.

605,213. LABEL-HOLDER. JOSEPH B. WELLER, De Graff, Ohio. Filed Sept. 3, 1897. Serial No. 650,454. (No model.)

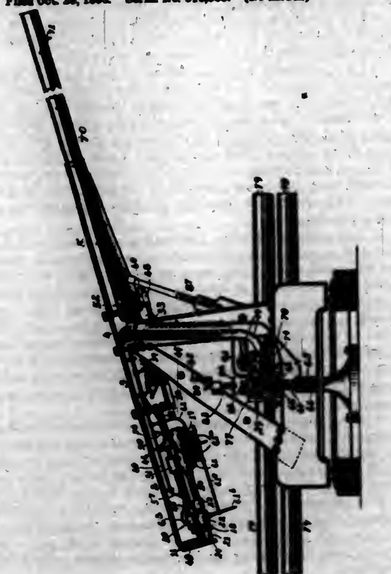
Claim.—As an article of manufacture, a label-holder comprising a base of thin elastic material, a pocket secured to the base and adapted to contain a number of labels, the base forming the rear wall of said pocket, and a tongue cut in the base and projecting into the pocket.



605,214. AXLELESS SPROCKET FOR BICYCLES. JOHN P. ARCHIBALD, Boston, Mass., assignor of one-half to Frank L. Whitcomb, same place. Filed Sept. 23, 1897. Serial No. 652,603. (No model.)

Claim.—1. An axleless sprocket in combination with a rotary member on each side thereof and transverse supports which pass through said sprocket and connect the rotary side members whereby the sprocket is supported and caused to rotate with said members, substantially as described.

2. In a bicycle or velocipede, rotary ring-cones to which the pedal-cranks are attached, fixed ring-boxes combined with the cones to hold the ball-bearings, and bolts which connect the cones, in combination with an axleless sprocket supported on said connecting-bolts, substantially as described.



605,215. SASH-BALANCE. MELVIN BARBER and JOHN P. ASHBY, Oklahoma, Okla., assignors of one-third to Joseph B. Rointer, same place. Filed Nov. 6, 1897. Serial No. 657,695. (No model.)

Claim.—1. The combination with a frame or casing, and an upper sash, of a lower sash having the guide devices, a rotatable, double, spring-controlled drum mounted on the head of said casing, guide-sheaves on the frame-head over the sashes, and a single continuous running cord coiled on the sections of the drum, extending thence around the guides of the lower sash, thence over the guide-sheaves, and attached to the upper sash, substantially as described.

2. In a sash-balance, the combination of a winding drum provided with an extended shaft, a tubular winding-shaft fitted loosely on the drum-shaft to rotate independently thereof and provided with means by which the tubular shaft may be rotated, a coiled spring fitted on the drum-shaft and attached at its ends to the tubular shaft and the drum respectively, and a detent device connected with said winding-shaft to restrain the latter from rotation under the recoil of the spring, substantially as described.

605,216. PNEUMATIC GUN. EDMUND M. T. BOGDAN, Melbourne, Victoria, assignor of one-tenth to George Garibaldi Turri, same place. Filed Oct. 29, 1896. Serial No. 610,505. (No model.)

Claim.—1. A pneumatic gun provided with a plurality of ports for fluid-pressure arranged along and opening into the bore, and increasing in size from the breech toward the muzzle, in combination with a source of fluid-pressure, and means for connecting the said ports *seriatim* to the said source of fluid-pressure, substantially as described.

2. A pneumatic gun provided with a plurality of ports for fluid-pressure arranged along and opening into the bore, and increasing in size from the breech toward the muzzle, in combination with a source of fluid-pressure, and means for connecting the said ports *seriatim* to the said source of fluid-pressure, and for automatically shutting off the fluid-pressure from the gun as the projectile leaves the bore, substantially as described.

3. A pneumatic gun provided with a plurality of ports for fluid-pressure arranged along and opening into the bore and increasing in size from the breech toward the muzzle, in combination with a source of fluid-pressure, means for connecting said ports *seriatim* to the source of fluid-pressure and means operated by the pressure in the bore of the gun in rear of the projectile for automatically shutting off the fluid-pressure from the gun as the projectile leaves the bore, substantially as described.

4. A pneumatic gun provided with a plurality of ports for fluid-pressure arranged along and opening into the bore, and increasing in size from the breech toward the muzzle, in combination with a source of fluid-pressure, and means operated by the pressure in the bore of the gun in rear of the projectile for automatically shutting off the fluid-pressure from the gun as the projectile leaves the bore, substantially as described.

5. In a pneumatic gun, the combination with a central tube provided with a plurality of fluid-pressure inlets therethrough arranged along the said tube, of jackets inclosing the rear portion of said tube, hollow trunnions integral with or secured to one of said jackets, passages connecting said inlets with one or both of said hollow trunnions, a source of fluid-pressure connected to one or both of said hollow trunnions, means for normally closing the connection between said air-inlets and said source of fluid-pressure, firing mechanism for admitting fluid-pressure to the said passages and also to the bore of the gun in rear of said projectile, and means operated by the pressure in the bore in rear of the projectile for opening said inlets *seriatim*, substantially as described.

6. In a pneumatic gun, the combination with a central tube provided with a plurality of fluid-pressure inlets therethrough arranged

along the said tube, of jackets inclosing the rear portion of said tube, hollow trunnions integral with or secured to one of said jackets, passages connecting said inlets with one or both of said hollow trunnions, a source of fluid-pressure connected to one or both of said hollow trunnions, means for normally closing the connection between said air-inlets and said source of fluid pressure, firing mechanism for admitting fluid-pressure to the said passages and also to the bore of the gun in rear of said projectile, and means operated by the pressure in the bore in rear of the projectile for opening said inlets *seriatim*, with means for shutting off the supply of fluid-pressure automatically as the projectile leaves the gun, substantially as described.

7. In a pneumatic gun, the combination with a source of fluid-pressure, of a gun-body provided with hollow trunnions and air-passages leading from one of said trunnions to the interior of the bore, the said passages opening at intervals along the bore, of valves controlling all of said openings, a pipe connecting the said hollow trunnion with the source of fluid-pressure, and a main valve controlling the flow of fluid through said pipe, firing mechanism for operating said main valve, and means operated by the pressure in the gun in rear of the projectile for operating the other valves *seriatim*, substantially as described.

8. In a pneumatic gun, the combination with a source of fluid-pressure, of a gun-body provided with hollow trunnions and air-passages leading from one of said trunnions to the interior of the bore, the said passages opening at intervals along the bore, of valves controlling all of said openings, a pipe connecting the said hollow trunnion with the source of fluid-pressure, and a main valve controlling the flow of fluid through said pipe, firing mechanism for operating said main valve, and means operated by the pressure in the gun in rear of the projectile for operating the other valves *seriatim*, and for closing said main valve as the projectile leaves the gun, substantially as described.

9. In a pneumatic gun, the combination with a source of fluid-pressure, of a gun-body provided with hollow trunnions and air-passages leading from one of said trunnions to the interior of the bore, the said passages opening at intervals along the bore, of valves controlling all of said openings, a pipe connecting the said hollow trunnion with the source of fluid-pressure, and a main valve controlling the flow of fluid through said pipe, a firing-lever for operating said main valve, and means operated by the pressure in the gun in rear of the projectile for operating the other valves *seriatim*, substantially as described.

10. In a pneumatic gun, the combination with a source of fluid-pressure, of a gun-body provided with hollow trunnions and air-passages leading from one of said trunnions to the interior of the bore, the said passages opening at intervals along the bore, of valves controlling all of said openings, a pipe connecting the said hollow trunnion with the source of fluid-pressure, and a main valve controlling the flow of fluid through said pipe, a firing-lever for operating said main valve, and means operated by the pressure in the gun in rear of the projectile for operating the other valves *seriatim* and for closing said main valve as the projectile leaves the gun, substantially as described.

11. In a pneumatic gun, the combination with a source of fluid-pressure, of a gun-body provided with hollow trunnions and air-passages leading from one of said trunnions to the interior of the bore, the said passages opening at intervals along the bore, of valves controlling all of said openings, a pipe connecting the said hollow trunnion with the source of fluid-pressure, and a main valve controlling the flow of fluid through said pipe, firing mechanism for operating said main valve, and means operated by the pressure in the gun in rear of the projectile for operating the other valves *seriatim*, a pipe leading from the bore of the gun near the muzzle, a cylinder connected to said pipe, and a piston in said cylinder moving said firing mechanism in the reverse direction and closing said main valve as the projectile leaves the gun, substantially as described.

12. In a pneumatic gun, the combination with a source of fluid-pressure, of a gun-body provided with hollow trunnions and air-passages leading from one of said trunnions to the interior of the bore, the said passages opening at intervals along the bore, of valves controlling all of said openings, a pipe connecting the said hollow trunnion with the source of fluid-pressure, and a main valve controlling the flow of fluid through said pipe, a firing-lever for operating said main valve, and means operated by the pressure in the gun in rear of the projectile for operating the other valves *seriatim*, a pipe leading from the bore of the gun near the muzzle, a cylinder connected to said pipe, and a piston in said cylinder moving said firing-lever in the reverse direction and closing said main valve as the projectile leaves the gun, substantially as described.

13. A pneumatic gun provided with a plurality of ports for fluid-pressure arranged along and opening into the bore, and increasing in size from the breech toward the muzzle, in combination with a source of fluid-pressure, and means for connecting the said ports *seriatim* to the said source of fluid-pressure, and means for automatically closing said ports before a fresh projectile can be inserted in the breech of the gun, substantially as described.

14. A pneumatic gun provided with a plurality of ports for fluid-pressure arranged along and opening into the bore, and increasing in size from the breech toward the muzzle, in combination with a source of fluid-pressure, and means for connecting the said ports *seriatim* to the said source of fluid-pressure, and for automatically shutting off the fluid-pressure from the gun as the projectile leaves the bore, and means for automatically closing said ports before a fresh projectile can be inserted in the breech of the gun, substantially as described.

15. A pneumatic gun provided with a plurality of ports for fluid-pressure arranged along and opening into the bore and increasing in size from the breech toward the muzzle, in combination with a source of fluid-pressure, and means operated by the pressure in the bore of the gun in rear of the projectile for automatically shutting off the fluid-pressure from the gun as the projectile leaves the bore, and means for automatically closing said ports before a fresh projectile can be inserted in the breech of the gun, substantially as described.

16. A pneumatic gun provided with a plurality of ports for fluid-pressure arranged along and opening into the bore, and increasing in size from the breech toward the muzzle, in combination with a source of fluid-pressure, means for connecting said ports *seriatim* to the source of fluid-pressure and means operated by the pressure in the bore of the gun in rear of the projectile for automatically shutting off the fluid-pressure from the gun as the projectile leaves the bore, and means for automatically closing said ports before a fresh projectile can be inserted in the breech of the gun, substantially as described.

17. In a pneumatic gun with slotted-screw breech mechanism, the combination with a source of fluid-pressure connected both to the bore of the gun and to the breech mechanism, and adapted both to propel the projectile and to operate the breech mechanism, of a pivoted carrier-ring, a slotted-screw breech-block adapted both to slide and to rotate in said ring, a fluid-pressure cylinder and piston operated from the source of fluid-pressure, and means operated by said piston for first rotating said breech-block and moving it rearward in said ring, and then swinging said ring outward about its pivot or vice versa, substantially as described.

18. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure connected both to the bore of the gun and to the breech mechanism, and adapted both to propel the projectile and to operate the breech mechanism, of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, and means operated by said piston operated from the source of fluid-pressure for first partially rotating said breech-block, then drawing said block rearward on said carrier, and then swinging said block and carrier outward about the pivot of said carrier, or vice versa, substantially as described.

19. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure connected both to the bore of the gun and to the breech mechanism, and adapted both to propel the projectile and to operate the breech mechanism of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston operated from the source of fluid-pressure, a valve and operating mechanism therefor for admitting fluid-pressure to said cylinder, and means operated by said piston for first partially rotating said breech-block, then drawing said block rearward on said carrier, and then swinging said block and carrier outward about the pivot of said carrier, or vice versa, substantially as described.

20. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure connected both to the bore of the gun and to the breech mechanism, and adapted both to propel the projectile and to operate the breech mechanism of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston operated from the source of fluid-pressure, a valve for admitting fluid-pressure to said cylinder, and a hand-lever and connecting parts for moving said valve, and means operated by said piston for first partially rotating said breech-block, then drawing said block rearward on said carrier, and then swinging said block and carrier outward about the pivot of said carrier, or vice versa, substantially as described.

21. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a screw fast to said piston, and means operated by said screw for first partially rotating said breech-block, then drawing said block rearward on said carrier, and then swinging said block and carrier outward about the pivot of said carrier, or vice versa, substantially as described.

22. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a screw fast to said piston, means for holding said screw against rotation, a revoluble collar mounted on said screw, and means operated by said screw and by said revoluble collar for first partially rotating said breech-block, then drawing said block rearward on said carrier, and then swinging said block and carrier outward about the pivot of said carrier, or vice versa, substantially as described.

23. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a screw fast to said piston and provided with a transverse notch therein, means for holding said screw against rotation, an arm on the breech-block adapted to engage in said notch when the block is unlocked, and means operated by said screw for turning said breech-block from the locking to the unlocking position, or vice versa, and for swinging said carrier and said block about the pivot of the carrier, substantially as described.

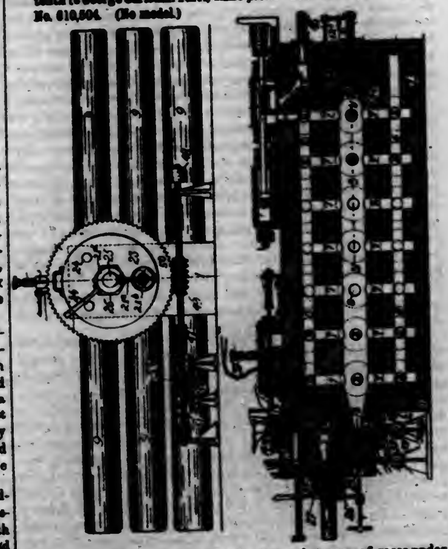
24. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a screw fast to said piston and provided with transverse notch therein, means for holding said screw against rotation, an arm on the breech-block adapted to engage in said notch when the block is unlocked, a revoluble collar on said screw and mechanism operated by said revoluble collar for turning the breech-block from the locking to the unlocking position or vice versa, and for swinging said carrier and said block about the pivot of the carrier, substantially as described.

25. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure, of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a valve and operating mechanism therefor for admitting fluid-pressure to said cylinder, a screw fast to said piston, and provided with a transverse notch therein, means for holding said screw against rotation, an arm on the breech-block adapted to engage in said notch when the block is unlocked, and means operated by said screw for turning said breech-block from the locking to the unlocking position, or vice versa, and for swinging said carrier and said block about the pivot of the carrier, substantially as described.

26. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a valve for admitting fluid-pressure to said cylinder, and a hand-lever and connecting parts for moving said valve, a screw fast to said piston and provided with a transverse notch therein, means for holding said screw against rotation, an arm on the breech-block adapted to engage in said notch when the block is unlocked, and means operated by said screw for turning said breech-block from the locking to the unlocking position, or vice versa, and for swinging said carrier and said block about the pivot of the carrier, substantially as described.

27. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a valve and operating mechanism therefor for admitting fluid-pressure to said cylinder, a screw fast to said piston, and means operated by said screw for first partially rotating said breech-block, then drawing said block rearward on said carrier, and then swinging said block and carrier outward about the pivot of said carrier, or vice versa, substantially as described.

28. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a valve for admitting fluid-pressure to said cylinder, and a hand-lever and connecting parts for moving said valve, a screw fast to said piston, and means operated by said screw for first partially rotating said breech-block, then drawing said block rearward on said carrier, and then swinging said block and carrier outward about the pivot of said carrier, or vice versa, substantially as described.



29. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a valve and operating mechanism therefor admitting fluid-pressure to said cylinder, a screw fast to said piston, means for holding said screw against rotation, a revoluble collar mounted on said screw, and means operated by said screw and by said revoluble collar for first partially rotating said breech-block, then drawing said block rearward on said carrier, and then swinging said block and carrier outward about the pivot of said carrier, or vice versa, substantially as described.

30. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a valve for admitting fluid-pressure to said cylinder, and a hand-lever and connecting parts for moving said valve, a screw fast to said piston, means for holding said screw against rotation, a revoluble collar mounted on said screw, and means operated by said screw and by said revoluble collar for first partially rotating said breech-block, then drawing said block rearward on said carrier, and then swinging said block and carrier outward about the pivot of said carrier, or vice versa, substantially as described.

31. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a valve and operating mechanism therefor for admitting fluid-pressure to said cylinder, a screw fast to said piston and provided with a transverse notch therein, means for holding said screw against rotation, an arm on the breech-block adapted to engage in said notch when the block is unlocked, a revoluble collar on said screw and mechanism operated by said revoluble collar for turning the breech-block from the locking to the unlocking position or vice versa, and for swinging said carrier and said block about the pivot of the carrier, substantially as described.

32. In a gun of the character described, provided with a slotted-screw breech mechanism, the combination with a source of fluid-pressure of a pivoted carrier, a slotted-screw breech-block adapted both to slide and to rotate on said carrier, a fluid-pressure cylinder and piston, a valve for admitting fluid-pressure to said cylinder, and a hand-lever and connecting parts for moving said valve, a screw fast to said piston and provided with a transverse notch therein, means for holding said screw against rotation, an arm on the breech-block adapted to engage in said notch when the block is unlocked, a revoluble collar on said screw and mechanism operated by said revoluble collar for turning the breech-block from the locking to the unlocking position or vice versa, and for swinging said carrier and said block about the pivot of the carrier, substantially as described.

603,217. PRODUCING AND STORING GAS UNDER HIGH PRESSURE. RICHARD M. T. BURBAN, Melbourne, Victoria, assignor of one-tenth to George Garibaldi Turri, same place. Filed Oct. 20, 1896. Serial No. 610,004. (No model.)

Claim.—1. The method of production and storage of gases under pressure which consists in successively firing a number of small charges of a smokeless explosive into a receiver or storage-chamber of sufficient strength, and automatically stopping the further firing of said

charges when the pressure in said receiver exceeds a predetermined limit, substantially as described.

2. The method of production, storage, and distribution of gases under pressure which consists in successively firing a number of small charges of explosive into a main receiver, and in automatically charging from said main receiver one or more secondary receivers whenever the pressure in said secondary receivers falls below a predetermined limit, substantially as described.

3. The method of production, storage, and distribution of gases under pressure which consists in successively firing a number of small charges of explosive into a main receiver, and in automatically charging from said main receiver one or more secondary receivers whenever the pressure in said secondary receivers falls below a predetermined limit, and also automatically stopping the further firing of said charges when the pressure in the main receiver exceeds a predetermined limit, substantially as described.

4. An apparatus for the production and storage of gases under pressure, comprising a plurality of strong hollow cylinders secured to a heavy chambered central piece, the chambers in said cylinders and in said central piece communicating with one another, means for successively firing a plurality of small charges into the said system of chambers, and means for automatically stopping the further firing of said charges when the pressure of the gases exceeds a predetermined limit, substantially as described.

5. An apparatus for the production and storage of gases under pressure, comprising a plurality of strong hollow cylinders secured to a heavy chambered central piece, the chambers in said cylinders and in said central piece communicating with one another, a firing-chamber in said central piece, a chambered disk for holding a plurality of small explosive charges, means for rotating said disk and causing said charges to register *seriatim* with said firing-chamber and means for firing said charges, substantially as described.

6. An apparatus for the production and storage of gases under pressure, comprising a plurality of strong hollow cylinders secured to a heavy chambered central piece, the chambers in said cylinders and in said central piece communicating with one another, a firing-chamber in said central piece, a chambered disk for holding a plurality of small explosive charges, means for rotating said disk and causing said charges to register *seriatim* with said firing-chamber, and means for firing said charges, means for successively firing a plurality of small charges into the said system of chambers, and means for automatically stopping the further firing of said charges when the pressure of the gases exceeds a predetermined limit, substantially as described.

7. An apparatus for the production and storage of gases under pressure, comprising a plurality of strong hollow cylinders secured to a heavy chambered central piece, the chambers in said cylinders and in said central piece communicating with one another, means for successively firing a plurality of small charges into the said system of chambers, and means for automatically stopping the further firing of said charges when the pressure of the gases exceeds a predetermined limit, comprising a piston, heavy springs bearing against the rear face of said piston and resisting the pressure in the central chamber, and stop mechanism operated by said piston and controlling the further movement of said chambered disk, substantially as described.

8. An apparatus for the production and storage of gases under pressure, comprising a plurality of strong hollow cylinders secured to a heavy chambered central piece, the chambers in said cylinders and in said central piece communicating with one another, a firing-chamber in said central piece, a chambered disk for holding a plurality of small explosive charges, means for rotating said disk and causing said charges to register *seriatim* with said firing-chamber, means for firing said charges, and means regulated by the rise of pressure of the gases for stopping the rotation of the chambered disk and the further firing of said charges, and thus automatically regulating the pressure to a predetermined limit, substantially as described.

9. An apparatus for the production and storage of gases under pressure, comprising a plurality of strong hollow cylinders secured to a heavy chambered central piece, the chambers in said cylinders and in said central piece communicating with one another, a firing-chamber in said central piece, a chambered disk for holding a plurality of small explosive charges, means for rotating said disk and causing said charges to register *seriatim* with said firing-chamber, and means for firing said charges, and means for automatically stopping the further firing of said charges when the pressure of the gases exceeds a predetermined limit, comprising a piston, heavy springs bearing against the rear face of said piston and resisting the pressure in the central chamber, and stop mechanism operated by said piston and controlling the further movement of said chambered disk, substantially as described.

10. An apparatus for the production, storage, and distribution of gases under pressure, comprising a main receiver and one or more secondary receivers connected thereto, means for successively firing a plurality of small charges of explosive material into said main receiver, and means for automatically charging and recharging said secondary receiver or receivers from the main receiver when the pressure in the secondary receiver or receivers falls below a predetermined limit, substantially as described.

11. An apparatus for the production, storage and distribution of gases under pressure, comprising a main receiver and one or more secondary receivers connected thereto, means for successively firing a plurality of small charges of explosive material into said main receiver, means for automatically checking the firing of said charges when the pressure in the main receiver exceeds a predetermined limit, and means for automatically charging and recharging said secondary receiver or receivers from the main receiver when the pressure in the secondary receiver or receivers falls below a predetermined limit, substantially as described.

12. An apparatus for the production, storage, and distribution of gases under pressure, comprising a main receiver and one or more secondary receivers connected thereto, each of said receivers comprising a heavy chambered central piece and a plurality of strong hollow cylinders secured thereto, the chambers in said cylinders and in said central piece communicating with one another, means for successively firing a plurality of small charges of explosive material into said main receiver, and means for automatically charging and recharging said secondary receiver or receivers from the main receiver when the pressure in the secondary receiver or receivers falls below a predetermined limit, substantially as described.

13. An apparatus for the production, storage and distribution of gases under pressure, comprising a main receiver and one or more secondary receivers connected thereto, each of said receivers comprising a heavy chambered central piece and a plurality of strong hollow cylinders secured thereto, the chambers in said cylinders and in said central piece communicating with one another, means for successively firing a plurality of small charges of explosive material into said main receiver, means for automatically checking the firing of said charges when the pressure in the main receiver exceeds a predetermined limit, and means for automatically charging and recharging said secondary receiver or receivers from the main receiver when the pressure in the secondary receiver or receivers falls below a predetermined limit, substantially as described.

14. An apparatus for the production, storage, and distribution of gases under pressure, comprising a main receiver and one or more secondary receivers connected thereto, means for successively firing a plurality of small charges of explosive material into said main receiver, and means for automatically charging and recharging said secondary receiver or receivers from the main receiver when the pressure in the secondary receiver or receivers falls below a predetermined limit, comprising a safety-valve on the secondary receiver, a spring-operated valve on the main receiver normally closing the connecting-passage from the main receiver to the secondary receiver, and means operated by the escape of fluid past said safety-valve for closing the former valve against the action of said spring, substantially as described.

15. An apparatus for the production, storage and distribution of gases under pressure, comprising a main receiver and one or more secondary receivers connected thereto, means for successively firing a plurality of small charges of explosive material into said main receiver, means for automatically checking the firing of said charges when the pressure in the main receiver exceeds a predetermined limit, and means for automatically charging and recharging said secondary receiver or receivers from the main receiver when the pressure in the secondary receiver or receivers falls below a predetermined limit, comprising a safety-valve on the secondary receiver, a spring-operated valve on the main receiver normally closing the connecting-passage from the main receiver to the secondary receiver, and means operated by the escape of fluid past said safety-valve for closing the former valve against the action of said spring, substantially as described.

16. An apparatus for the production, storage, and distribution of gases under pressure, comprising a main receiver and one or more secondary receivers connected thereto, means for successively firing a plurality of small charges of explosive material into said main receiver, and means for automatically charging and recharging said secondary receiver or receivers from the main receiver when the pressure in the secondary receiver or receivers falls below a predetermined limit, comprising a perforated safety-valve on the secondary receiver, a spring-operated slide-valve on the main receiver and normally closing the connecting-passage from the main receiver to the secondary receiver, a piston-rod fast to said valve, a piston on said rod, and a cylinder inclosing said piston and connected to the escape-pipe from said safety-valve, substantially as described.

17. An apparatus for the production, storage and distribution of gases under pressure, comprising a main receiver and one or more secondary receivers connected thereto, means for successively firing a plurality of small charges of explosive material into said main receiver, means for automatically checking the firing of said charges when the pressure in the main receiver exceeds a predetermined limit, and means for automatically charging and recharging said secondary receiver or receivers from the main receiver, when the pressure in the secondary receiver or receivers falls below a predetermined limit, comprising a perforated safety-valve on the secondary receiver, a spring-operated slide-valve on the main receiver and normally closing the connecting-passage from the main receiver to the secondary receiver, a piston-rod fast to said valve, a piston on said rod and a cylinder inclosing said piston and connected to the escape-pipe from said safety-valve, substantially as described.

18. In an apparatus of the character described the means for controlling the pressure in the main receiver which consists of a piston, subjected on one side to the pressure of the gases, strong cup-springs bearing on the other side of said piston, a piston-rod projecting from said piston and apparatus regulated by the motion of said piston against said springs for checking the further discharge of pressure-producing charges, substantially as described.

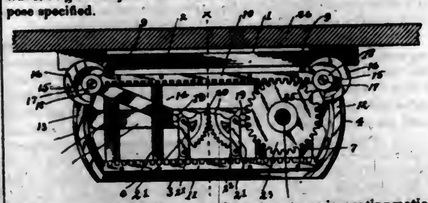
19. In an apparatus of the character described the means for controlling the pressure in the main receiver which consists of a piston subjected on one side to the pressure of the gases, strong cup-springs bearing on the other side of said piston, a piston-rod projecting from said piston and stop mechanism operated by the motion of said piston-rod for stopping the operation of the pressure-producing apparatus, substantially as described.

20. In an apparatus of the character described, the combination with a firing-chamber, of a centrally-pivoted disk provided with a plurality of cartridge-chambers grouped in a circle about said pivot, means for imparting a step-by-step motion to said disk, means for separately supplying primers to the apparatus, and means for firing said primers, substantially as described.

21. In an apparatus of the character described, the combination with a firing-chamber, of a centrally-pivoted disk provided with a plurality of cartridge-chambers grouped in a circle about said pivot, means for imparting a step-by-step motion to said disk, means for separately supplying primers to the apparatus, and means for automatically firing said primers, substantially as described.

22. In an apparatus of the character described, the combination with a firing chamber, of a centrally-pivoted disk provided with a plurality of cartridge-chambers grouped in a circle about said pivot, means for simultaneously imparting a step-by-step motion to said disk, and for separately supplying primers to the apparatus, and means for firing said primers, substantially as described.

23. In an apparatus of the character described, the combination with a firing-chamber, of a centrally-pivoted disk provided with a plurality of cartridge-chambers grouped in a circle about said pivot, means for imparting a step-by-step motion to said disk, means for separately supplying primers to the apparatus, and means for firing said primers with means operated by the pressure of the gases for stopping the motion of said disk when the pressure exceeds a predetermined limit, substantially as described.

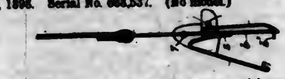


24. In an apparatus of the character described, the combination with a firing-chamber, of a centrally-pivoted disk provided with a plurality of cartridge-chambers grouped in a circle about said pivot, means for imparting a step-by-step motion to said disk, means for separately supplying primers to the apparatus, and means for automatically firing said primers, with means operated by the pressure of the gases for stopping the motion of said disk when the pressure exceeds a predetermined limit, substantially as described.

25. In an apparatus of the character described, the combination with a firing-chamber, of a centrally-pivoted disk provided with a plurality of cartridge-chambers grouped in a circle about said pivot, means for simultaneously imparting a step-by-step motion to said disk, and for separately supplying primers to the apparatus, and means for firing said primers, with means operated by the pressure of the gases for stopping the motion of said disk when the pressure exceeds a predetermined limit, substantially as described.

26. In an apparatus of the character described, the combination with a firing-chamber, of a centrally-pivoted disk provided with a plurality of cartridge-chambers grouped in a circle about said pivot, means for simultaneously imparting a step-by-step motion to said disk, and for separately supplying primers to the apparatus, and means for automatically firing said primers, with means operated by the pressure of the gases for stopping the motion of said disk when the pressure exceeds a predetermined limit, substantially as described.

605,218. MECHANISM FOR CONVERTING ROTARY TO RECIPROCATING MOTION. JOHN W. BUTTERFIELD, Columbus, Ohio. Filed Jan. 19, 1898. Serial No. 667,147. (No model.)



Claim.—1. In a mechanism for converting rotary to reciprocating motion, the combination with a frame 1 having curved end tracks, driving-arms fulcrumed to said frame and having a segmental gear connection at their inner ends, heads on the outer ends of said driving-arms, said heads having a sliding connection with said tracks, and a pin projecting from each of said heads, of a vertically-movable frame 6, an upper and lower rack-bar carried thereon, bars 21 jointedly connecting said frame 6 and driving-arm a power-shaft and a pinion-wheel on said shaft having a peripheral recess, the teeth of said pinion adapted to engage alternately with said rack-bars, the pins of said driving-arm heads adapted to engage as described with said pinion-recesses and a guide projection on said pinion adapted to travel in guideways on said heads, substantially as and for the purpose specified.

2. In a mechanism for converting rotary to reciprocating motion, the combination with a frame 1, a curved track on each end thereof, opposing driving-arms fulcrumed to said frame 1 and having a segmental gear connection at their inner ends, and a head on each of said driving-arms, a guideway on each of said heads said heads having a sliding connection with said end tracks and a projecting pin on each of said heads, of a frame 6 vertically movable in said frame 1, bars 21 jointedly connecting said driving-arms and said movable frame, a rotating shaft 24, a pinion carried thereon, the latter having a peripheral recess and a guide-roller projecting therefrom adapted to travel in the guideways of the arm-heads, substantially as and for the purpose specified.

3. In a mechanism for converting rotary to reciprocating motion, the combination with a frame 1, a curved track on each end thereof, opposing driving-arms fulcrumed to said frame 1, driving-arm heads having a sliding connection with said tracks, a curved flange on each of said heads, and a pin projecting from each of said heads concentric with the curve of said flange, of a vertically-movable frame 6 connected with said frame 1 and having a jointed connection with the driving-arms, a rotary shaft 24, a pinion 23 thereon, a peripheral recess in said pinion adapted to receive as described said head-pins and a roller projecting from said pinion and adapted to travel against said head-flanges, substantially as and for the purpose specified.

605,219. CLASP. JAMES L. CARNEY, New York, N. Y. Filed Jan. 31, 1898. Serial No. 668,537. (No model.)

Claim.—The clasp herein set forth comprising a body-plate having a slot at one end for a webbing or elastic fabric, jaw-teeth at the other end and pivots upon opposite edges, the clamping-plate having jaw-teeth at one end and integral pivot-ears and a spring at the other end, there being holes in the ears receiving the pivots of the body-plate and a lever-plate pivoted to the ears of the clamping-plate and having cams to act on the surface of the body-plate as the lever-plate is swung from one position to the other to open and close the jaws, substantially as set forth.

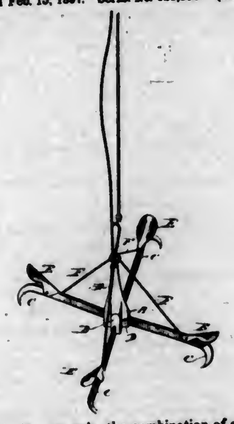
605,220. FODDER-COMPRESSOR. JAMES B. CARTER, Culpeper, Va. Filed Aug. 9, 1897. Serial No. 647,822. (No model.)

Claim.—1. A bundle-compressor comprising two levers, two curved compressing-arms intermediately connected to the inner sides of the levers, the inner ends of the compressing-arms swingingly connected to each other, substantially as described.

2. A bundle-compressor comprising two levers, rectangular in cross-section, curved compressor-arms connected to the inner sides of one end of the levers, the inner ends of the compressor-arms swingingly connected to each other, whereby the levers form a base when the compressor is unfolded for receiving the material to be compressed, substantially as described.

3. A bundle-compressor comprising two levers, curved compressor-arms secured intermediate their ends to the inner sides of the levers, one end of the compressor-arms swingingly connected to each other, substantially as described.

4. A bundle-compressor comprising two levers, curved compressing-arms secured to the inner sides of one end of the levers and having one of their ends swingingly connected to each other, and a holding-loop at the opposite or handle ends of the levers, substantially as described.



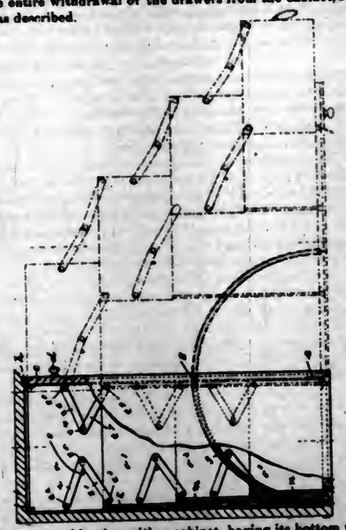
5. A bundle-compressor comprising two levers, curved compressing-arms having at their outer sides two connecting-points attached to the inner sides of the levers to hold the arms rigid therewith, one end of the compressing-arms swingingly connected to each other, and their opposite ends left free to separate, substantially as described.

6. A bundle-compressor comprising two levers, curved compressing-arms secured to the inner sides of the levers at one end thereof, the compressing-arms swingingly connected to each other at one end, one end of the levers having a hook to receive one end of a binding-twine and the other a friction device to receive the other end of the cord, the parts operating in the manner and for the purpose described.

7. A bundle-compressor comprising two levers, curved compressing-arms secured intermediate their ends to the inner sides of the levers, and at one end thereof, one end of the compressing-arms swingingly connected to each other and the other and free ends of the compressing-arms being elongated and curved outward, substantially as described.

8. A bundle-compressor comprising two levers, curved compressing-arms secured to the inner sides of the levers near one end thereof, the inner ends of the compressing-arms swingingly connected to each other, and the adjacent ends of the levers extended to form projections to prevent the rolling of the bundle after being compressed, substantially as described.

605,221. GRAPPLING-HOOK. THEOPHILE DAVID, Corunna, Canada. Filed Feb. 15, 1897. Serial No. 623,533. (No model.)

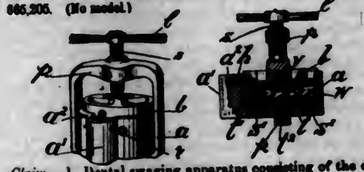


Claim.—1. In a grapple, the combination of a head, hooks pivoted to said head, at angles to each other, and having pivoted spreaders, and means adapted to spread said hooks, substantially as set forth.

2. In a grapple, the combination of a head, hooks pivoted to said head, at angles to each other, and having pivoted spreaders and spreading cords or lines adapted to spread said hooks, substantially as set forth.

605,222. EXHIBITING-CABINET. ALFRED GARTNER, Paterson, N. J., assignor to the Inventor's Novelty Manufacturing Company, same place. Filed Aug. 16, 1897. Serial No. 648,354. (No model.)

Claim.—1. The combination with a cabinet, of a door or front hinged to the front portion of the bottom of said cabinet, a series of drawers in said cabinet, means for pivotally connecting said drawers, a leg downwardly projecting from the rear portion of each drawer, a pin inwardly projecting from the front portion of each side of the cabinet, and a slotted arc-shaped link engaging its respective pin and secured with its forward end to the hinged front or door, substantially as described.

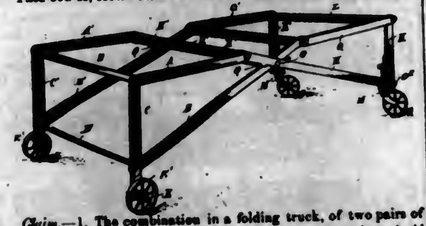


2. The combination with a cabinet, of a door or front hinged to the front portion of the bottom of said cabinet, a series of drawers in said cabinet, means for pivotally connecting said drawers, a leg downwardly projecting from the rear portion of each drawer, a pin inwardly projecting from the front portion of each side of the cabinet, a slotted arc-shaped link engaging its respective pin and secured with its forward end to the hinged front or door, and means carried by one of said drawers and by the cabinet respectively for preventing the entire withdrawal of the drawers from the cabinet, substantially as described.

3. The combination with a cabinet, having its bottom provided with a central groove or recess, of a door or front hinged to the front portion of said bottom and provided with a groove or recess communicating and in alinement with the groove or recess in said bottom, a series of drawers in said cabinet, means for pivotally connecting said drawers, a leg downwardly projecting from the rear portion of each drawer and provided at its lower end with an enlargement engaging the groove or recess in the bottom of the cabinet, a pin inwardly projecting from the front portion of each side of the cabinet, a slotted arc-shaped link engaging its respective pin and secured with its forward end to the hinged front or door, and means carried by one of said drawers and by the cabinet respectively for preventing the entire withdrawal of the drawers from said cabinet, substantially as described.

4. The combination with a cabinet having its bottom provided with a central groove or recess, of a door or front hinged to the front portion of said bottom and provided with a groove or recess communicating and in alinement with the groove or recess in said bottom, a series of drawers in said cabinet, means for pivotally connecting said drawers, a leg downwardly projecting from the rear portion of each drawer and provided at its lower end with an enlargement engaging the groove or recess in the bottom of the cabinet, a pin inwardly projecting from the front portion of each side of the cabinet, and a slotted arc-shaped link engaging its respective pin and secured with its forward end to the hinged front or door, substantially as described.

605,223. APPARATUS FOR SWAGING DENTAL PLATES. JOHN H. GARTRELL, Penzance, England. Filed Dec. 31, 1897. Serial No. 666,205. (No model.)



Claim.—1. Dental swaging apparatus consisting of the cylinder *a* having a recess *a'* closed by a plug a^2 held in position by the rod *r*, the plunger *b* and screw-press *p* as described.

2. A dental swaging apparatus comprising the cylinder *a* having a recess *a'* in one side thereof, the tray in the bottom of the cylinder having a handle projecting into said recess, the plug adapted to close said recess, the plunger, the water-cushion adapted to be placed between the plunger and the article to be pressed and the metal balls adapted to encircle the article to be pressed, substantially as described.

3. A dental swaging apparatus comprising the cylinder *a* having a recess in the side thereof, the plug a^2 having a rounded face and a sustaining-rib *f*, the plunger and the screw, for applying pressure thereto, substantially as described.

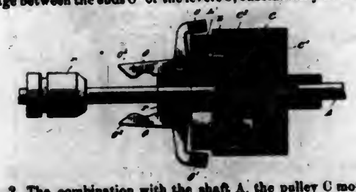
605,224. COLLAPSIBLE TRUCK. CASPER GREEN, Dublin, Ind., assignor of one-half to Ottis Craner and James Hammon, same place. Filed Oct. 15, 1897. Serial No. 655,285. (No model.)

Claim.—1. The combination in a folding truck, of two pairs of end uprights C, C' and K, K', two pairs of horizontal top bars A, A' and G, G', each pair being pivoted at its outer ends to the upper ends of the end uprights, the inclined bars B, B' pivotally connected at their outer lower ends to the end uprights C, C' and at their inner upper ends to the inner ends of the horizontal top bars G, G', and the inclined bars H and H' pivoted at their lower outer ends to the uprights K, K' and at their inner upper ends to the inner ends of the top bars A, A', the two pairs of bars B, B' and H, H' being crossed near their inner upper ends and pivotally connected together at their crossing, substantially as described.

2. The combination in a folding truck, of end uprights and horizontal top bars, with inclined bars pivotally connecting the inner ends of the top bars with the lower ends of the opposite end uprights, said inclined bars being crossed near their inner upper ends and pivoted together, and each of them being provided with a laterally-projecting stop, substantially as described.

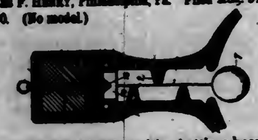
3. The combination in a folding truck, of end uprights C, C' and K, K', top bars A, A' and G, G' and inclined bars B, B' and H, H', cross-bar D' pivotally connecting the outer lower ends of the inclined bars B, B' with the lower ends of the upright bars C, C', the cross-bar D pivotally connecting the outer ends of the top bars A, A' with the upper ends of the end uprights C, C', the cross-bar N' pivotally connecting the inner ends of the top bars A, A' with the upper ends of the inclined bars H and H', the cross-bar O pivotally connecting the two sets of inclined bars B, B' and H, H' at their point of crossing near their inner upper ends, the cross-bar N pivotally connecting the upper ends of the inclined bars B, B' with the inner ends of the top bars G, G', the cross-bar L pivotally connecting the outer ends of the top bars G, G' with the upper ends of the end uprights K, K', the pins O^2 pivotally connecting the lower ends of the inclined bars H, H' with the lower ends of the uprights C, C', and casters M, M' mounted on the lower ends of the uprights K, K', substantially as described.

605,225. GARMENT-SUPPORTER. MYRON B. HARMON, Bridgeport, Conn. Filed Sept. 17, 1897. Serial No. 652,096. (No model.)



Claim.—1. A garment-support comprising a stud and a slotted metal plate carried by a tape, and the flexible non-elastic loop secured in position intermediate of said plate and stud which loop does not extend to the bottom of the slot in said plate, substantially as set forth.

2. In a garment-support comprising a stud and a metal plate carried by a tape, said plate having a slot enlarged at the top and contracted at the bottom, the flexible non-elastic loop secured in position in parallelism with said slot, the lower end wall of the latter extending beyond the lower end of the loop whereby said stud will be suspended wholly by said loop and without contact against said wall, substantially as set forth.



605,226. REVERSING-GEAR. JOHN H. HARE, Noblesville, Ind. Filed Oct. 1, 1896. Serial No. 607,883. (No model.)

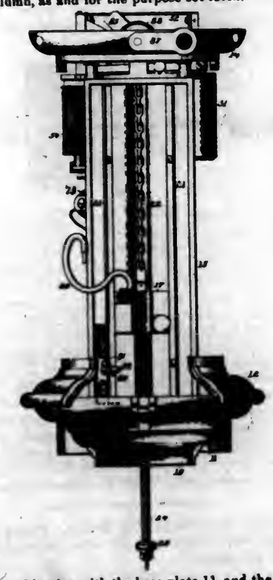
Claim.—1. The combination of the shaft A, the pulley C mounted to rotate thereon having enlarged hub C' on one side and internal gear-teeth C^2 on the other, the sleeve D on the shaft adjacent to the hub C', the elbow brake-levers E having the beveled outer ends, a sliding collar F' having a conical end to pass between said levers, brake-shoes E' on the opposite end of the levers engaging the hub C', the disk L mounted on the shaft, the disk L provided with annular flanges L', the pinions M journaled on the disk L and meshing with the interior gear-teeth C^2 and the pinion N, the sleeve P, the elbow brake-levers O pivoted to sleeve P having their outer ends O^2 beveled and carrying brake-shoes O' to engage the flange L', and the sliding collar R on the shaft provided with tapered or conical end to engage between the ends O^2 of the levers O, substantially as described.

2. The combination with the shaft A, the pulley C mounted to rotate thereon having enlarged hub C' on one side and internal gear-teeth C^2 on the other, the sleeve D on the shaft adjacent to the hub C', the elbow brake-levers E having the beveled outer ends, a sliding collar F' having a conical end to pass between said levers, brake-shoes E' on the opposite end of the levers engaging the hub C', the disk L mounted on the shaft, provided with flanges L', the pinion N rigidly mounted on the shaft, the disk L provided with annular flanges L', the pinions M journaled on the disk L and meshing with the interior gear-teeth C^2 and the pinion N, the sleeve P, the elbow brake-levers O pivoted to sleeve P having their outer ends O^2 beveled and carrying brake-shoes O' to engage the flange L', the sliding collar R on the shaft provided with tapered or conical end to engage between the ends O^2 of the levers O, the shifting rod H parallel with the shaft, the lever I pivoted to the shaft-hanger and attached to the rod H, and the bifurcated arms G and S whose forks operate in annular grooves in the sliding collars F' and R, substantially as described.

605,227. NON-REFILLABLE BOTTLE. GEORGE E. HENRY and CHARLES F. HENRY, Philadelphia, Pa. Filed Aug. 31, 1897. Serial No. 650,100. (No model.)

Claim.—1. In combination with a bottle, a keeper secured in the mouth thereof, said keeper having grooves formed in its sides, wires extending across said grooves, a detector secured to the keeper whereby when said keeper is withdrawn the detector will indicate the fact, a stopper carrying catches adapted to engage the cross-wires of the keeper, as and for the purpose described.

2. In combination, a bottle having a neck in which a circuitous passage is formed, a mouth of larger interior diameter, a keeper located within the mouth and resting upon shoulders, a wire, a detector suspended from the keeper by said wire, a protector adapted to fit upon the keeper, means for attaching said protector to the keeper, and a stopper to which the protector is secured, substantially as shown and described.



3. In combination with a bottle of the character described, a keeper adapted to fit within the mouth thereof and rest upon suitable shoulders, said keeper having grooves formed in its sides, cross-wires extending across said grooves, a protector adapted to fit upon the keeper, catch-hooks carried by said protector for engagement with the cross-wires, a stopper secured to the protector, a wire suspended from the keeper, and a detector secured to the lower end of this wire, substantially as and for the purpose set forth.

4. In combination with a bottle, a keeper secured in the mouth thereof, said keeper having grooves formed in its sides, wires extending across said grooves, a detector secured to the keeper whereby when said keeper is withdrawn the detector will indicate the fact, a protector, a cork secured on said protector, and catches formed of a single piece of sheet metal, said piece of metal being secured between the cork and protector, the ends thereof being bent downwardly and hooked to engage the cross-wires of the keeper, substantially as set forth.

605,228. ELECTRIC-ARC LAMP. WILLIAM HOCHHAUSEN, Brooklyn, N. Y. Filed Jan. 22, 1897. Serial No. 620,222. (No model.)

Claim.—1. In an arc-lamp, the casing containing the operating mechanism in combination with a vertical partition dividing the space inclosed by said casing into two chambers one of them containing the mechanism to which access must be had in trimming, and means for gaining ready access to said chamber from the exterior without opening into the other chamber, substantially as set forth.

2. In the arc-lamp substantially as shown and described, the combination with the upper and lower ends or plates, of the chambered column 13, connecting them and the casing A extending from one plate to the other and provided with the door for closing the chamber in said column, as and for the purpose set forth.

3. The combination with the base-plate 11, and the top plate 14, suitably capped, of the chambered column joining said plates, the ring 12, provided with the door, and the casing extending from the ring 12, to the plate 14, and provided with a door which coöperates with the aforesaid door to close the chamber in said column, as and for the purpose set forth.

4. The combination with the connected carbons, of the longitudinally-movable shaft from which they are suspended, a clutch member fixed upon said shaft, the coöperating clutch member sleeved upon the shaft, means for moving said shaft longitudinally to throw the clutch members together as the arc is struck, and an electric motor operated by the current of the lamp and geared to said sleeve, for the purpose set forth.

5. The combination with the pivoted frame, the longitudinally-movable shaft journaled thereon, the carbons operated from said shaft, a spring resting against one end of the shaft, a triangular lever pivoted to the frame and bearing against the other end of the shaft, means for tilting the frame and thereby causing longitudinal movement of the shaft, feeding mechanism for rotating the shaft, and a clutch device operated by said longitudinal movement to engage the shaft with the feeding mechanism, for the purpose set forth.

6. The combination with the arc-striking magnet 31, the feeding-magnets 54 and their armature, of a supplemental armature located out of the normal field of said feeding-magnets and operated thereby only under an abnormal strength of current through said magnets, a shunt around the feeding-magnets completed by the movement of said supplemental armature, and a magnet in said shunt for holding the armature in circuit-closing position, substantially as set forth.

7. The combination with the feeding-magnets in a shunt from the arc-circuit, of the elbow-armature having one arm opposite the poles of the feeding-magnets to be attracted thereby under an abnormal strength of current through the shunt, a shunt around the feeding-magnet maintained normally open, a fixed contact, and a contact carried by said armature for closing said normally open shunt, and a magnet in circuit with said contacts and acting upon the other arm of said armature for holding them in engagement.

8. In an arc-lamp, the combination with the arc-circuit, of the feeding-magnet shunt, the normally open safety-shunt around the feeding-magnet, a resistance in said shunt so proportioned with relation to the arc-circuit as to insure the resumption of the regular feeding operation, and the automatic cut-out shunt for the lamp around the arc inclosing the feeding-magnet circuit and said resistance, substantially as set forth.

9. A terminal clamp consisting of a plate folded upon itself to receive a terminal wire in the fold, in combination with a triangular lever pivoted at one angle between said folds and bearing at an outer angle against an inserted terminal wire, and a screw mounted between the folds of the plate and bearing against the other outer angle of said lever, substantially as set forth.

605,229. PHOTOGRAPHIC-PRINT WASHER. WILLIAM H. LEIGH, Beaver Falls, Pa. Filed June 9, 1897. Serial No. 640,063. (No model.)

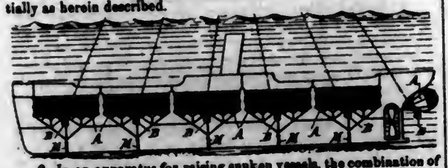
Claim.—1. In a device of the class described, the combination with a rockably-mounted tray, of partitions extending thereacross which have overflow-openings near their upper edges that lead into the pockets formed by said partitions, and valves unseated when the tray is rocked to discharge the fluid from the pocket filled.

2. The herein-described device comprising a tray, a perforated false bottom therefor, partitions in the tray which divide the same into a central tank and end pockets, pipes leading from the space between the main and false bottoms into the pockets and provided with open ends, pockets having outlet or discharge openings, valves adapted to close the openings of the pipes and the outlet-openings aforesaid, said valves having tripping-stems which extend through the outlet-openings, and a fulcrum located intermediate the ends of the tray.

3. The combination with the rockably-mounted tray having transverse partitions near each end with perforations near their upper edges, a perforated false bottom with an outlet between the bottoms, vertical pipes located between the said partitions and ends of the tray and connecting with the space between the two bottoms, outlet-pipes connected with the said pipes and extended downwardly with their lower ends over openings in the bottom of the tray, and valves slidingly mounted on the outlet-pipes and provided each with a perforation, a head and a depending stem, all substantially as shown and described.

4. The combination of a tray having partitions and perforated false bottom, the outlet-pipes and the sleeves surrounding the same and provided each with a perforation in its side wall, a bottom adapted to close the end of the pipe and an opening in the bottom of the tray, and a stem depending from the said bottom and through the opening in the bottom of the tray, substantially as and for the purpose specified.

605,230. BRUSH. LAVINE A. LIGHTENDORF, Olney, Pa. Filed Oct. 18, 1897. Serial No. 655,506. (No model.)



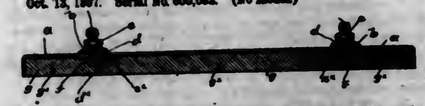
Claim.—1. In a brush, the combination with a cap having a handle, of a tapered ferrule having an abrupt contraction e, at its smaller end, and adapted for engagement with a portion of said cap, bristles having their cemented butts within said ferrule, and a concavo-convex disk interposed between the cap and mass of cemented butts, substantially as herein specified.

2. In a brush, the combination with a cap having a handle and provided with an externally-threaded flange c, of an interiorly-threaded tapered ferrule in engagement with the flange, bristles having their cemented butts within said ferrule, and a concavo-convex disk E, bearing on the flange and exerting a pressure on the mass of cemented bristles, substantially as herein specified.

605,231. MEANS FOR RAISING SUNKEN VESSELS. LAURENT MATHESON, La Garenne-Colombes, France. Filed Nov. 30, 1897. Serial No. 660,308. (No model.)

Claim.—1. In an apparatus for raising sunken vessels, the combination of a float, an acetylene-generator connected and having communication with said float and comprising a cylindrical receiver containing an eccentric compartment with perforated walls and an opening in its bottom, a perforated basket for carbid adapted to be introduced into said compartment through the said opening, a hermetic seal between the said opening and the bottom of said basket, a valve for admitting water to said receiver, and means for operating said valve from a point above the level of the water distant from the vessel and float for the purpose of admitting water to said receiver, substantially as herein described.

2. In an apparatus for raising sunken vessels, the combination of a float, an acetylene-generator attached to and having communication with said float, a valve for admitting water to said generator, a normally open electric circuit in which is an electromagnet the armature of which is attached to said valve, a circuit-closer in said circuit and means for operating said circuit-closer at a point above the level of the water distant from the vessel and float, substantially as herein described.



3. In an apparatus for raising sunken vessels, the combination of a float having rigid walls, an acetylene-gas generator within said float, a water-escape valve in said float, a second valve between said float and generator for the admission to the latter of water from the former, a third valve between said float and generator to admit to the former acetylene gas from the latter, and means for operating the said second and third valves from a point above the level of the water distant from the vessel and float, substantially as herein described.

605,232. ATTACHMENT FOR RUBBER SHOES. CHARLES R. POST, Winfield, Kans. Filed Mar. 23, 1897. Serial No. 628,705. (No model.)

Claim.—An overshoe provided with an attachment mounted in the walls of the overshoe so that the latter will present smooth inner surfaces to the foot of the wearer, and constructed from a single piece of spring sheet metal, and comprising a vertically-disposed stem having its lower end bent to form a step, and curved arms extending laterally from each side of the stem at the upper end thereof and arranged around the upper edge of the heel portion of the overshoe and reinforcing and stiffening such edge and forming a clamp to engage the foot of the wearer, the step being supported on the sole of the overshoe and the stem being arranged midway between the sides of the latter and extending from the sole to the upper edge of the overshoe to prevent the heel from breaking down, substantially as described.

605,233. RAILWAY-TIE. MICHAEL RILEY, London, Ohio. Filed Oct. 13, 1897. Serial No. 655,023. (No model.)

Claim.—1. In a railway-track support, the combination with a metallic tie-plate and a tongue cut therefrom and shaped to conform to the side of a track-rail, of a doubled metallic strip *d* shaped to conform to and bear against the inner side of said track-rail, a key-plate *c* passing through the doubled lower end of said strip *d* beneath said plate *a* and transverse bolts *e* adapted to clamp said tongue and strip end portions against opposite sides of said track-rail web, substantially as and for the purpose specified.

2. In a railway-track support, the combination with a metallic tie-plate or casing and a tongue cut therefrom and shaped to conform to the side of a track-rail, a metallic strip *d* extending through the opening formed by the cutting of said tongue and secured in connection with said plate, a bolt *e* uniting the strip *d*, tongue *b* and a track-rail web, of a filling for said flange plate or casing *a* of concrete or similar material, substantially as and for the purpose specified.

605,234. SMOKE-BELL. TRUMAN C. O. SHERK, Buffalo, N. Y. Filed Dec. 14, 1897. Serial No. 661,810. (No model.)

Claim.—1. A smoke-bell, comprising a bell portion, a suspending medium, an asbestos-supporting device, and devices for detachably securing the suspending medium to the bell portion and the asbestos-supporting device within the bell portion.

2. A smoke-bell, comprising a bell portion provided with a series of draft-openings, a net suspended within said bell portion and a series of asbestos portions loosely suspended from said net.

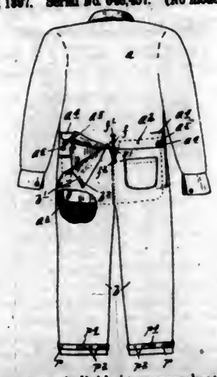
3. A smoke-bell, comprising a bell portion, provided with a series of openings in its top, a net, a series of asbestos portions loosely suspended from said net, a supporting chain or chains, and devices passed through the openings in the top of the bell portion for detachably securing the chain or chains to the bell portion and the net within the interior of the bell portion, as set forth.

605,235. AUTOMATIC WAGON-BRAKE. EDGARD SUNNER, Tipton, Kans. Filed May 19, 1897. Serial No. 637,261. (No model.)

Claim.—1. In a wagon-brake, the combination of the brake-lever loosely supported from the wagon-body and carrying the brake-shoes at its ends, and a suitable connection between the brake-lever and thills, whereby any back draft on them will apply the brake-shoes, substantially as shown and described.

2. In a wagon-brake, the combination of the brake-lever loosely supported from the wagon-body and carrying the brake-shoes at its ends, an arc-shaped piece having a loose connection with the brake-lever, and a connection with the thills substantially as shown and described.

3. In a wagon-brake, the combination with a rock-shaft mounted upon the wagon-body and carrying brake shoes at its ends, a transversely-extending rod having its extremities bent to extend beneath the front axle, and a loose connection between said transverse bar and the rock-shaft, of the thills connected to the extremities of the transverse bar and adapted by their longitudinal movement to actuate the rock-shaft and apply the brake-shoes, substantially as set forth.



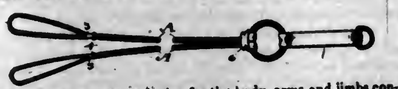
4. In a wagon-brake, the combination with the rock-shaft carrying brake-shoes at its extremities, clips secured upon the front axle and perforated, a transversely-extended rod having its extremities bent to pass beneath the axle, said bent ends passing through the perforated clips and movable therein, and a loose connection between the transverse rod and the rock-shaft, of the thills connected to the extremities of the transverse rod, substantially as set forth.

5. In a wagon-brake, the combination with a rock-shaft having an intermediate crank portion and carrying brake-shoes at its extremities, an arc-shaped piece having its extremities bent to extend forwardly, guides carried by the axle in which said forwardly-extending ends move, and a longitudinally-extending bar secured to the arc-shaped piece and loosely connected to the crank of the rock-shaft, of the thills connected to the extremities of the arc-shaped piece, substantially as set forth.

6. In a wagon-brake, the combination with a rock-shaft mounted upon the body of the wagon and carrying brake-shoes at its extremities, a transversely-extending rod having its forwardly-extending ends bent, guides carried by the axle in which said forwardly-extending ends move, a connection between the transversely-extending rod and the rock-shaft, and springs arranged about the ends of the

transversely-extending rod between the extremities thereof and the guides, of the thills connected to the extremities of said transversely-extending rod, substantially as set forth.

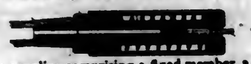
605,236. OVERALLS. CHARLES G. SMITH, Minneapolis, Minn.
Filed July 30, 1897. Serial No. 646,457. (No model.)



Claim.—1. A union-suit divided transversely at the back between the body and leg portions, and having an expansion-fold extending downwardly from the body portion and folded upon itself so as to form the plait a^2, a drop-flap extending from the leg portion and closing upwardly, and fastenings for releasably closing the expansion-fold and drop-flap together at the sides of the garment, the plait a^2 being permanently attached to the body portion at its ends in line with the side fastenings, and being unattached thereto between its ends, whereby the garment is adapted to be opened and closed at the rear as desired, and is rendered vertically expansible at the back, and non-expansible at the sides.

2. A union-suit divided transversely at the back between the body and leg portions, and having an expansion-fold extending downwardly from the body portion below the line of division and folded upon itself so as to form a plait a^2 and the tailpiece a^3, a drop-flap extending from the leg portion and closing upwardly, and fastenings for releasably closing the expansion-fold and drop-flap together at the sides of the garment, the plait a^2 being permanently attached to the body portion at its ends in line with the side fastenings, and being unattached thereto between its ends, whereby the garment is adapted to be opened and closed at the rear as desired, and is rendered vertically expansible at the back, and non-expansible at the sides.

3. A union-suit divided transversely at the back between the body and leg portions, and having an expansion-fold extending downwardly from the body portion below the line of division and folded upon itself so as to form the plait a^2 and the tailpiece a^3, a drop-flap extending from the leg portion and closing upwardly between the plait a^2 and the tailpiece a^3, non-elastic fastenings for releasably closing the expansion-fold and drop-flap together at the sides, and elastic fastenings for releasably securing said plait and flap together at the middle, the plait a^2 being permanently attached to the body portion at its ends in line with the side fastenings, and being unattached thereto between its ends, whereby the garment is adapted to be opened and closed at the rear as desired, and is rendered vertically expansible at the back, and non-expansible at the sides.



605,237. EXERCISING DEVICE. FENTON R. SPINK, Cleveland, Ohio.
Filed Jan. 11, 1896. Serial No. 534,536. (No model.)

Claim.—An exercising device for the body, arms and limbs consisting of an elastic strap or strand, means to engage one end thereof to a fixed object, a ring at the opposite end thereof, an elastic strap or strand provided with elastic handholds and secured by looping to the ring, substantially as set forth.

605,238. AUTOMATIC HOSE-COUPLING. WILLIS A. SUTTER, Marysville, Cal.
Filed Mar. 1, 1897. Serial No. 625,457. (No model.)

Claim.—1. An improved coupling, comprising a uniting and holding device, a socket portion carried thereby open from end to end, a tube longer than the socket and extending therethrough and provided with enlargements on opposite sides of the socket, the space between the enlargements being longer than the socket, and a spring arranged between the forward enlargement and the socket for holding the tube normally extended toward the holding device, the opposite end of the tube being adapted to connect with a hose or other pipe.

2. A pipe-coupling comprising a fixed member, a movable member adapted to move within the fixed member, the fixed member provided with gripping members for holding one section of the piping to be coupled, the other section of the piping to be coupled adapted to be attached to the movable member, and means for holding the movable member in engagement with the section of piping secured by the gripping members substantially as shown and described.

3. A hose-coupling, comprising a gripping member adapted to receive and hold one section of the pipe to be coupled, a section of pipe or tube movable upon the gripping member and adapted to receive the other section of pipe to be coupled, and means for holding the opposite end of the movable pipe pressed against the pipe held by the gripping member, substantially as described.

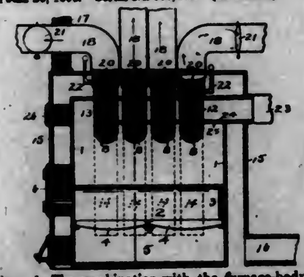
4. The combination of a collar, spring-arms secured to said collar, jaws carried by the opposite end of said arms and adapted to receive one section of the pipe to be coupled, a tube movable in said collar and adapted to receive the other section of the pipe to be coupled, at its outer end and at its inner end adapted to engage the section of pipe held by the jaws, and means for holding said tube pressed against said pipe, substantially as described.

5. The combination of a collar, spring-arms secured thereto, jaws formed on the opposite ends of said arms and adapted to hold one section of the pipe to be coupled, a tube movable through the collar and adapted to receive the other section of the pipe to be coupled, means for holding the opposite end of said tube in engagement with the section of pipe held by the jaws, and a ring movable upon said spring-arms for the purpose of preventing their disengagement from the section of pipe held thereby, substantially as described.

6. A pipe-coupling comprising a collar, gripping members carried thereby and adapted to hold one section of the pipe to be coupled, a tube movable through the collar to which the other section of the pipe to be coupled is adapted to be secured, means for holding said tube normally in engagement with the section of pipe held by the gripping member, a perforated cap upon the opposite end of said tube, a perforated pin movable in the tube and normally pressed outward and a stop upon said pin for limiting its outward movement, substantially as described.

605,239. PNEUMATIC DISPLAY-LAST. WILLIAM J. THILL, Waukon, Iowa.
Filed June 30, 1897. Serial No. 642,980. (No model.)

Claim.—1. A display-last for shoes comprising in its construction an inflatable bag formed to approach in shape the interior of the shoe, when inflated, a wooden supporting-plug within said bag, and a metallic frame secured to said plug within said bag, and means for adjusting the size of the metallic frame, substantially as described.



2. A display-last for shoes comprising in its construction an inflatable bag formed to approach the shape of the interior of the shoe, when inflated, a wooden supporting-block having front notches, and an elastic metallic supporting-frame attached to the supporting-block within said bag and having its upper end inserted in one of said recesses, substantially as described.

3. A display-last for shoes comprising in its construction an inflatable bag formed to approach the shape of the interior of the shoe, when inflated, a wooden supporting-block having a rear recess, an elastic, metallic, supporting-frame attached to the supporting-block within the bag, having its rear end extending up the back part of the bag, and an adjusting-screw projecting from the recess in the block and bearing against said rear end, substantially as described.

4. The combination with the inflatable bag, of the wooden plug

secured therein and provided with a series of recesses in its front end, the flexible metallic frame F having its front end inserted in one of said recesses, an adjusting-screw G projecting rearwardly from the plug and serving to distend the rear end of said metallic frame, and suitable means for connecting a pump for the purpose of inflating the bag, substantially as described.

605,240. FURNACE. CHARLES W. TROTTER, Rochester, N. Y.
Filed Jan. 29, 1898. Serial No. 668,423. (No model.)

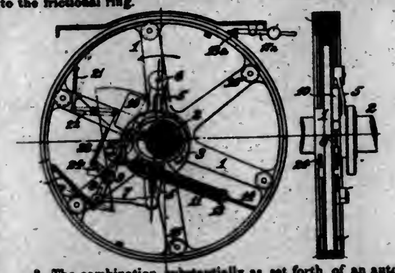
Claim.—1. The combination with the furnace-body having the fire-box and smoke-pipe, of the pipes arranged substantially horizontally over the fire-box provided with the vertical extensions, the partitions therein, and the depending supply pipes at the ends, the outer casing, the conductor-pipe leading therefrom, and means for connecting the extensions directly with the conductors, substantially as described.

2. The combination with the furnace-body having the fire-box and the smoke-pipe, the horizontal air-pipes arranged over the fire-box, and forming a smoke-flue between said pipes and the top of the furnace-body, and a cleaning-aperture arranged in the body in line with the smoke-flue over the pipes, substantially as described.

3. The combination with the furnace-body having the fire-box and smoke-pipe, the substantially horizontal air-pipes having the depending supply-pipes at the ends, and the central discharge extensions, of the outer casing, the air-conductors leading therefrom, and movable pipe collars or sleeves for connecting the discharge extensions of the horizontal pipes with the conductor-pipes, substantially as described.

4. The combination with the furnace-body and the fire-box and smoke-pipe, of the horizontal air-pipes extending over the fire-box and below the smoke-pipe and forming a flue at the top of the body and between it and the pipes, a casing around the furnace-body, conductor-pipes leading from the top thereof, and detachable pipe connections between the horizontal air-pipes and the conductor-pipes, substantially as described.

5. The combination with the furnace-body having the fire-box, the horizontal air-pipes arranged above the fire-box having the vertical extensions passing through the furnace-body, and the partitions therein, of the outer casing, the conductor-pipes connected thereto and having dampers therein, and means for connecting the vertical extensions of the horizontal pipes directly with the conductor-pipes or permitting them to discharge into the casing, substantially as described.



6. The combination with the furnace-body having the fire-box, the horizontal air-pipes arranged above the fire-box, having vertical extensions passing above the furnace-body, of the outer casing, the conductor-pipes leading therefrom, the vertically-adjustable collars cooperating with the pipe extensions and with the conductor-pipes, substantially as described.

7. In a furnace, the combination with the furnace-body, and the fire-box, air-pipes passing over the fire-box and discharging above the furnace-body, of the outer casing, the conductor-pipes connected therewith and adjustable collars for connecting the pipe extensions with the conductor-pipes, substantially as described.

605,241. FLUID-MOTOR GOVERNOR. EDWIN F. WILLIAMS, New York, N. Y.
Filed Mar. 2, 1897. Serial No. 626,662. (No model.)

Claim.—1. The combination, substantially as set forth, of an automatic cut-off governor, an adjustable eccentric controlled thereby, a frictional mechanism for effecting the retardation of speed of a member rotating with the governor and independent thereof, and independently-operable and oppositely-acting connections from said frictional mechanism to the eccentric.

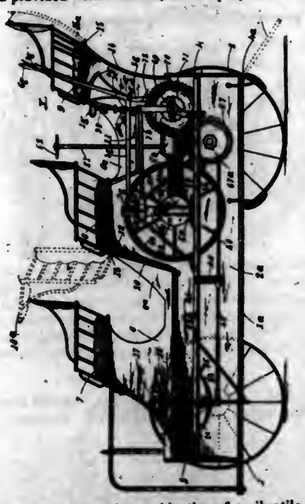
2. The combination, substantially as set forth, of an automatic cut-off governor, an adjustable eccentric controlled thereby, sheaves journaled on the carrier or frame of the governor, a frictional ring mounted freely upon said sheaves, connections coupling said frictional ring with the eccentric, and a brake-lever fitted to apply resistance to the frictional ring.

3. The combination, substantially as set forth, of an automatic cut-off governor, an adjustable eccentric controlled thereby, two frictional rings fitted to rotate with the governor, each having the capacity of independent circumferential movement thereon, connections coupling the frictional rings, in opposite directions, to the eccentric, and means for applying resistance to either of the frictional rings.

605,242. STOVE OR OTHER GRATE. ANTONIO ALITTO, Chicago Ill.
Filed Oct. 18, 1897. Serial No. 655,613. (No model.)

Claim.—1. The combination with grate-sections arranged side by side, bearings located in line with the central longitudinal ends of each section, upon which they rock, and means for rocking said sections simultaneously, of a clearing-rake reciprocable on ways beneath said sections and having teeth extending up between the longitudinal grate-bars, and means whereby said rake is allowed to pass beyond one end of said sections, to permit them to be rocked.

2. The combination with grate-sections arranged side by side, an inclosing fire-box, a journal-plate set out from the rear wall of said fire-box to form a guard-recess, pierced frame-plates for the rear ends of the grate-bars, bearings in the journal-plates and in the front wall of the fire-box in line with the central longitudinal axis of each grate-section for the support of such section, means for rocking the sections simultaneously, and a reciprocable clearing-rake arranged to pass said pierced support and into the guard-recess.



605,243. MOTOR-CARRIAGE. HENRY R. REED, Buffalo, N. Y.
Filed Mar. 8, 1897. Serial No. 626,494. (No model.)

Claim.—1. In a motor-carriage, the combination of the operating-motor, an arm adapted to be vibrated by said motor; a pawl-arm and toothed driving-wheel mounted on the same shaft, a pawl mounted on the pawl-arm and capable of a rotating and a vertical movement and having its upper end pivoted to a slotted bar and its lower end in engagement with the driving-wheel, a vertically-movable bar having its lower end connected by a pin with the slot in the slotted bar and its upper end provided with a handle, and a connection between the vibratile arm and the pawl-arm for operating the pawl-arm, as set forth.

2. In a motor-carriage, the combination of a vibratile arm pivoted to a support on the carriage-frame, a motor for giving it a uniform vibrating movement, a toothed driving-wheel an arm mounted on said driving-wheel shaft and carrying a pawl adapted to engage with the teeth in said driving-wheel, means for keeping the pawl in engagement with a yielding force, a connecting-arm pivotally connected with the pawl-arm and having its opposite end pivoted to a sliding piece adapted to slide up or down on the vibratile arm, and means for moving its pivotal center on the sliding piece in a line with the pivotal center of the vibratile arm, and thereby stopping the vehicle, or moving it from the pivotal center of the vibratile arm, for the purpose of varying the speed of the vehicle, as above set forth.

3. In a motor-carriage, the combination with the motor and mechanism for operating the pawl-arm, of a pawl-arm and toothed driving-wheel mounted on the same shaft, a pawl mounted on the pawl-arm and capable of a rotating and a vertical movement and having its upper end pivoted to a slotted bar and its lower end in

engagement with the driving-wheel, a vertically-movable bar having its lower end connected by a pin with the slot in the slotted bar and its upper end provided with a handle, for the purposes described.

4. In a motor-carriage, the combination of a vibratile arm pivoted to the supporting-frame, a motor and means for operating said arm, a toothed driving-wheel, a pawl-arm mounted on the same shaft with the driving-wheel and carrying a pawl in engagement with the teeth in said driving-wheel, a connecting-arm pivotally connected with the vibratile arm and the pawl-arm, and means within reach of the operator for lifting said pawl out of engagement with the teeth in the driving-wheel and thereby instantly stopping the propelling force of the vehicle.

5. In a motor-carriage, the combination of a vibratile arm pivoted to the support on the supporting-frame, a motor and connecting means for operating said arm, a toothed driving-wheel, a pawl-arm carrying a pawl adapted to engage with the teeth on said driving-wheel and mounted on the same shaft therewith, and an arm pivotally connecting it with the vibratile arm, a rod extending up from said pawl above the pawl-arm and pivoted to a slotted bar, a vertical bar provided with a handle, mounted in bearings so it can be moved easily up or down or turned therein, and connected with the slot in said slotted bar by a pin, and means for securing it when turned and set for either a forward or backward movement of the carriage, as above described.

6. In a motor-carriage, the combination with the supporting-frame, the operating-motor having its shaft provided with a crank device and the rear wheels of the carriage and their shaft, of a vibratile arm pivoted at or near its upper end to the frame and having a longitudinal slot at or near its lower end in which the crank device is supported and travels, a spur gear-wheel rigidly mounted on the rear-wheel shaft, a short supplementary shaft journaled upon the frame, a spur gear-wheel also mounted upon said supplementary shaft, and adapted to gear with the gear-wheel upon the main shaft, a second gear-wheel mounted upon the supplementary shaft, a forked arm adapted to fit over each side of the gear-wheel and pivotally mounted on the supplementary shaft so as to swing thereon, a pawl supported by said forked arm and adapted to engage with the teeth in the gear-wheel, a connecting-rod pivoted at or near the top of the forked arm, a spring to give a slight amount of elasticity to the forward thrusts of said arm, a slideway portion at the opposite end of the connecting-rod adapted to fit the vibratile arm and means for longitudinally moving said slideway upon the vibratile arm, as set forth.

7. In a motor-carriage, the combination with the supporting-frame, the operating-motor, and the wheels of the carriage, of a vibratile arm pivoted at one end to the frame and connected at the other to the motor-crank, a shaft journaled in the frame, a gear-wheel connected with the carriage-wheels, a pawl having a beveled lower end forming a driving edge on one side, a supporting device for said pawl, swinging pivotally from the gear-wheel shaft, means for nominally holding said pawl driving edge in engagement with the gear-wheel, a connecting-rod pivoted to the upper end of the supported device, a slideway on the opposite end of said rod adapted to fit and move longitudinally on the vibratile arm, an arm within reach of the operator for moving said rod and slideway portion upon the vibratile arm to vary the length of the strokes of the connecting-rod and thereby vary the speed of the carriage, and an arm within reach of the operator for disengaging the pawl from the gear-wheel and thereby stopping the transmission of power, or for disengaging and half-rotating the pawl, to reverse the running direction of the carriage, as set forth.

8. In a motor-carriage, the combination of a slotted vibratile arm pivoted to a support on the carriage-frame, an operating-motor having a crank-arm adapted to slide in the slot in the vibratile arm for imparting a uniform vibrating movement to said arm, a driving-wheel, an operating-arm mounted on said driving-wheel shaft and carrying a device adapted to detachably engage with the driving-wheel, means for keeping said device in engagement with a yielding force, a connecting-arm pivotally connected with the operating-arm and having its opposite end pivoted to a sliding piece adapted to slide up or down on the vibratile arm, means for moving its pivotal center on the sliding piece in a line with the pivotal center of the vibratile arm, and thereby stopping the movement of the operating-arm, or moving it from the pivotal center of the vibrating arm, for the purpose of varying the speed of the vehicle, and means for disengaging the operating-arm and its device from or changing its position thereon and thereby stopping the transmission of power or reversing the running direction of the carriage, as set forth.

9. The combination with the supporting-frame, the operating-motor and its shaft, and the driven wheels of the carriage, of a vibratile arm swinging from a pivot on the supporting-frame and having a slot in which the crank of the operating motor-shaft is sustained and travels, a toothed gear-wheel, a pawl-arm provided with a pawl having a beveled lower end forming a driving edge on one side, a rod connecting said pawl-arm to the vibratile arm to vibrate the same and means for rotating the pawl to present its driving edge to one side or the other of the teeth on the gear-wheel, as set forth.

10. In a motor-carriage, the combination with the supporting-frame, the operating-motor, and the wheels of the carriage, of an arm vibrated by the operating-motor, a gear-wheel in connection with the driven wheels of the carriage, a swinging arm having a pawl engaging with the gear-wheel, a connecting-rod between the vibratile arm and an arm within reach of the operator for varying the position of the connecting-rod with respect to the vibrated arm to lengthen or shorten the strokes of the swinging arms and correspondingly increase or decrease the speed of the carriage, as set forth.

11. In a motor-carriage, the combination with the carriage body and frame, of a shaft rotatably supported in the frame, and provided with a steering-wheel at its upper end and a bevel-gear at or near its lower end, a screw-bar unrotatably supported while free to move longitudinally, a bevel-gear held in engagement with the bevel-gear on the shaft and engaging with the screw-thread on the bar to control the longitudinal movement of said bar, and rods connecting said screw-bar with the front wheels to steer the vehicle, as set forth.

12. In a motor-carriage, the combination with the carriage and its frame, of a steering-wheel shaft mounted in suitable bearings near the rear of the carriage and carrying a steering-wheel at its top and a bevel gear-wheel at its foot, a screw-bar mounted in boxes in a substantially horizontal position, provided with a screw-thread on a portion of its surface and adapted to move back and forth in its bearings without turning therein, a bevel gear-wheel in engagement with the bevel gear-wheel at the foot of the steering-wheel shaft, mounted on said screw-bar and in engagement with the screw-thread thereon, means for preventing it from moving longitudinally in its bearings while free to rotate, a connecting-rod having one end pivoted to the screw-bar, and its opposite end pivoted to a transverse bar centrally pivoted to the under side of the carriage-frame, two short axle-bars pivoted to the frame, front wheels rotatably mounted on the outer ends of said axle-bars, and connecting the ends of the transverse bar with the axle-bars for turning them, and thereby steering the vehicle.

13. In a motor-carriage, the combination with the frame of two short axle-bars pivotally sustained by the front portion of said frame, the front wheels rotatably mounted at the outer ends of said bars, a transverse bar centrally pivoted to the frame, rods connecting the ends of said bar with the inner ends of the axle-bars, a bar having a peripheral screw-thread mounted at or near the rear of the frame and having a longitudinal movement only, a rod connecting the front end of said screw-threaded bar with the transverse bar, a gear-wheel engaging with the screw-thread upon said bar, and means within reach of the operator for rotating said gear-wheel and moving the screw-threaded bar longitudinally, as set forth.

14. In a motor-carriage, the combination with the frame, of two short axle-bars pivotally sustained by the front portion of said frame, the front wheels rotatably mounted at the outer ends of said bars, a transverse bar centrally pivoted to the frame, rods connecting the ends of said bar with the inner ends of the axle-bars, a bar having a peripheral screw-thread mounted at or near the rear of the frame and having a longitudinal movement only, a rod connecting the forward end of said screw-threaded bar with the transverse bar, a bevel gear-wheel engaging with the screw-thread upon the bar, and an arm within control of the operator and provided with a bevel gear-wheel meshing with the bevel gear-wheel engaging with the screw-threaded bar, as set forth.

15. In a motor-carriage, the combination with the frame and the steering-wheels, and their supporting-axles, of a peripherally-screw-threaded bar, unrotatably supported by said frame while free to move longitudinally, devices connecting said bar to the axles, a bevel gear-wheel inclosed within the frame portion supporting the screw-threaded bar and having an interiorly-screw-threaded opening encircling the screw-bar and adapted to engage with the screw-thread thereon, and an operating-rod provided at its lower end with a bevel gear-wheel meshing with the gear-wheel encircling the screw-bar, as set forth.

16. In a motor carriage, the combination with the frame, of two short front axles pivotally supported at their ends by said frame, wheels journaled at the outer ends of said axles, a transverse bar pivoted centrally to the frame, rods connecting the bar to the axles, a peripherally-screw-threaded bar, unrotatably supported by said frame while free to move longitudinally, rods connecting said screw-bar to the transverse bar, a bevel gear-wheel inclosed within the frame portion supporting the screw-threaded bar and having an internally-screw-threaded opening encircling the screw-bar, and adapted to engage with the screw-thread thereon and an operating-rod provided with a hand-wheel at its upper end and at its lower end with a bevel gear-wheel meshing with the gear-wheel encircling the screw-bar, whereby the rotation of the hand-wheel upon the operating-rod in either direction will cause its gear-wheel to rotate the gear-wheel encircling the screw-bar, and thereby move the screw-bar backward or forward according to the direction of the rotation, and through the connecting-rod move the transverse bar upon its central pivot and correspondingly the front axles and wheels, thereby steering the carriage, as set forth.

17. In a motor-carriage the combination with the front wheels, of a carriage, of two short axle-bars supporting the said front wheels, a brace extending down from the bolster and laterally each way in which the lower extension portions of the axle-bars are pivoted, two connecting-rods each having one end pivoted to a horizontal axle-bar and their opposite ends pivoted to a transverse bar pivoted centrally to the machinery platform, a connecting-bar pivoted to one end of the transverse centrally-pivoted bar and having its opposite end pivoted to a screw-bar carrying a bevel gear-wheel mounted in a support so that while it cannot move backward or forward it is free to rotate, a vertical steering-bar mounted in suitable bearings and having at its top a hand-wheel and at its foot a bevel gear-wheel in engagement with the bevel gear-wheel on the screw-bar, as set forth.

18. In a motor-carriage, the combination of a steering-wheel shaft mounted in suitable bearings near the rear of the carriage, and carrying a steering-wheel at its top and a bevel gear-wheel at its foot, a screw-bar mounted in boxes in a substantially horizontal position, provided with a screw-thread on a portion of its surface and adapted to move back and forth in its bearings without turning therein, a bevel gear-wheel in engagement with the bevel gear-wheel at the foot of the steering-wheel shaft, mounted on said screw-bar and in engagement with the screw-thread thereon, means for preventing it from moving longitudinally in its bearings while free to rotate, a connecting-rod having one end pivoted to the screw-bar, and its opposite end pivoted to a transverse bar centrally pivoted to the under side of the carriage-frame, and connecting-rods connecting the ends of the transverse bar with the front wheels for turning them and thereby steering the vehicle.

19. In a motor-carriage, the combination with the front wheels of a carriage, of two short axle-bars carrying the front wheels, each provided with an upper and lower pivotal extension, ball-bearings in the upper extensions upon which the ends of the bolster rest and are pivotally secured, a brace extending down from the bolster and laterally each way in which the lower extension portions of the axle-bars are pivoted, and mechanism pivoted to the inner ends of the axle-bars and having pivotal connections with the steering mechanism, for operating the two front wheels simultaneously and thereby steering the carriage.

20. In a motor-carriage, the combination with the front wheels of a carriage, of two short axle-bars carrying the front wheels, each provided with an upper and lower pivotal extension, ball-bearings in the upper extensions upon which the ends of the bolster rest and are pivotally secured, a brace extending down from the bolster and laterally each way in which the lower extension portions of the axle-bars are pivoted, two connecting-rods each having one end pivoted to a horizontal axle-bar and their opposite ends pivoted to a transverse bar pivoted centrally to the machinery platform, a connecting-bar pivoted to one end of the transverse centrally-pivoted bar and having its opposite end pivoted to a screw-bar carrying a bevel gear-wheel mounted in a support so that while it cannot move forward or back it is free to rotate, a vertical steering-bar mounted in suitable bearings and having at its top a hand-wheel and at its foot a bevel gear-wheel in engagement with the bevel-wheel on the screw-bar, as set forth.

21. In a motor-carriage, the combination with the engine and its supporting-platform, of spring mechanism for limiting the upward movement of said engine and platform and means for adjusting said spring mechanism to regulate its limiting movement.

22. In a motor-carriage, the combination of the carriage-body, its supports, springs interposed between said carriage-body and said support, the operating-engine, an independent supplementary support for said engine, springs interposed between said engine-support and the carriage-support, and an india-rubber cushion interposed between the engine and its support to deaden and partially prevent the transmission of the sound and vibration of the engine.

23. In a motor-carriage, the combination with the engine, its supporting-platform and springs interposed between said engine and supporting-platform, of supplementary springs for limiting the upward movement of said engine and supporting-platform, and means to adjust said springs to regulate their limiting movement.

24. In a motor-carriage, the combination of the engine and its supporting-platform, a layer of india-rubber between said engine and its supporting-platform, and springs for limiting the upward movement of said engine and platform.

25. In a motor-carriage, the combination with the engine, its supporting-platform and the rubber cushion interposed between said engine and supporting-platform, of supplementary springs for limiting the upward movement of said engine, and supporting-platform.

26. In a motor-carriage, the combination with the engine, its supporting-platform and the rubber cushion interposed between said engine and supporting-platform, of supplementary springs for limiting the upward movement of said engine and supporting-platform, and means to adjust said springs to regulate their limiting movement.

27. In a motor-carriage, the combination with the semi-elliptic springs, secured below the bolster and supporting-frame, upon which the frame or platform for supporting the engine and operating mechanism rests, of a bolt extending up from the lower spring and bolster and up above the top of the supporting-frame, a spiral spring resting on said supporting-frame and over said bolt, and a nut for readjusting said springs

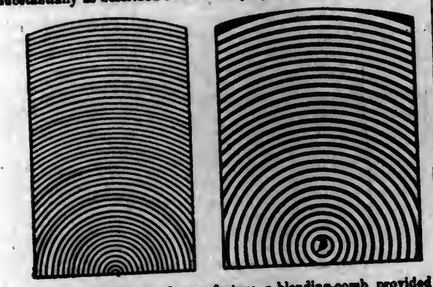
28. In a motor-carriage, the combination with the engine, its supporting-platform and springs interposed between said engine and supporting-platform of supplementary springs for limiting the upward movement of said engine and supporting-platform, and means to adjust said springs to regulate its limiting movement.

29. A motor-carriage, comprising the body provided with removable end, side and top portions, an operating-motor supported upon springs within said body, the carriage-supporting frame and running-gear and springs interposed between said frame and gear and the carriage-body.

30. A motor-carriage, comprising a carriage-body forming an inclosing case, a motor within said case, a motor-supporting frame, springs supporting said supporting-frame and means for allowing a slight backward or forward movement to said springs, as set forth.

31. A motor-carriage, comprising a carriage-body, its support, the operating machinery, an independent support for said machinery, and springs interposed between said independent support and the carriage-support, means for allowing a slight backward or forward movement to said springs and supplemental springs for limiting the upward movement of said independent support.

32. A motor-carriage, comprising the carriage-body, its support, the operating-motor, an independent support for said motor, double-acting springs for restraining said independent support with a spring force in both an upward and downward direction, means for regulating said springs and means for allowing a slight forward or backward movement thereto, as set forth.



33. In a motor-carriage, the combination with the motor, of the body, forming an inclosing case for said motor, and comprising the bottom, sides, front portion, rear portion hinged at its lower edge to the bottom, the side pieces, seats supported upon said side pieces and forming removable portions of said body or inclosing case, and a removable platform, as set forth.

34. In a motor-carriage, the combination with the motor and operating mechanism, of the carriage-body forming an inclosing case for said motor and operating mechanism, and having hinged seats and rear end portion whereby the motor and operating mechanism are exposed when required, as set forth.

605,244. GRAINING. JOHN J. CALLOW, Cleveland, Ohio. Filed Nov. 13, 1896. Serial No. 611,944. (No model.)

Claim.—1. The method of graining in imitation of wood, which consists in coating the surface thereof to be grained, with graining color then drawing over said colored surface, a flexible pad provided with concentric lines on its under side, and at the same time drawing a grainer's comb over the top surface of said pad at a speed different from that at which the pad is moving, substantially as described.

2. The method of graining in imitation of wood, which consists in coating the surface thereof to be grained, with graining color then drawing over said coloring surface a flexible pad provided with concentric lines on its under side, and at the same time drawing a grainer's comb over the top surface of said pad at a speed different from that at which the pad is moving, and finally striking the said grained work against the grain thereof with a flexible bleeding-comb, substantially as described and for the purpose herein set forth.

3. As a new article of manufacture, a bleeding-comb, provided with flexible teeth, a hook on the end of each of said teeth, and a band or web of rubber tightly stretched around said comb and covering said hooked teeth, substantially as described.

605,245. PHOTOGRAPHIC FINDER. HARVEY B. GARLTON, Rochester, N. Y. Filed Mar. 27, 1897. Serial No. 629,509. (No model.)

Claim.—1. A finder for a camera, consisting of a body having a lens tube and a mirror, in combination with a plate pervious to light above the mirror, the plate being made hollow at its upper surface and a body adapted to roll placed therein, substantially as shown and described.

2. A finder for a camera, consisting of a hollow body provided with a lens-tube and an inclined mirror, in combination with a plate pervious to light, above the mirror, the plate being made hollow at its upper surface, and a body, as a sphere, adapted to roll placed in said hollow, and four retaining walls or sides together forming a rectangular inclosure for the sphere, substantially as shown and described.

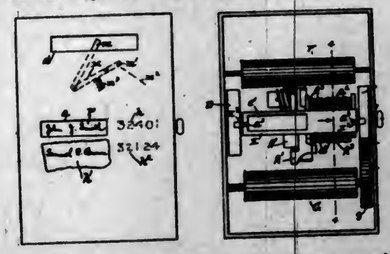
3. A finder for a camera, consisting of a body provided with a lens-tube and a mirror, in combination with a plate pervious to light, above the mirror, made hollow at its upper surface, and a body, as a sphere, adapted to roll placed in said hollow, and four walls or sides together forming a rectangular inclosure for the sphere, the plate being provided with two intersecting lines one parallel with two opposing retaining walls or sides and the other parallel with the remaining two walls or sides, substantially as specified.

4. In combination a lens and an inclosed mirror, a plate pervious to light, above the mirror, made hollow at its upper surface, and a body, as a sphere, adapted to roll placed in said hollow, and means for confining said sphere upon the plate, substantially as shown and described.

5. In a finder for cameras, the combination, with a support, of a plate therein pervious to light, the upper surface of the plate being hollowed, a body adapted to roll within the hollow, and means for passing rays of light through the plate from the bottom to form an image, substantially as set forth.

6. In a finder for cameras, the combination, with a lens-tube provided with an inclosure, the bottom of the inclosure being pervious to light and having its upper surface hollowed, of a spherical body within the hollow, and means for passing rays of light through the plate from within the tube to form an image, substantially as described.

7. The combination, with a camera, of a lens-tube, provided with an inclosure, the bottom of said inclosure being pervious to light and having its upper surface provided with a hollow, of a spherical body within the hollow, and a mirror within the tube below the bottom of the inclosure and adapted to throw rays of light through said bottom, substantially as set forth.



8. The combination, with a camera, of a tube secured thereto, provided with an inclosure, the bottom of the inclosure being pervious to light and hollow upon its upper surface, the hollow portion being provided with intersecting lines, of a spherical body within the hollow, and an inclined reflector below the bottom of the inclosure, substantially as set forth.

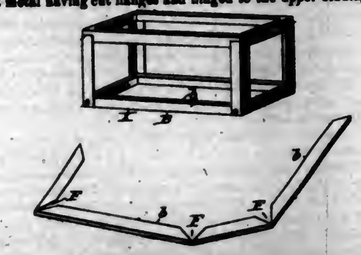
605,246. BISMUTH METHYLENE-DI-GALLATE AND PROCESS OF MAKING IT. RENNE DÜRRENT, Darmstadt, Germany, assignor to The Firm of E. Merck, same place. Filed May 26, 1896. Serial No. 593,174. (Specimens.) Patented in Germany June 18, 1895, No. 87,009.

Claim.—1. The process of making a new astringent and antiseptic chemical compound directly from a freshly-prepared hydroxid of bismuth and methylene-di-gallic acid; by precipitating such hydroxid from a bismuth salt through the action of an alkali in the presence of water; washing the precipitate; and then allowing methylene-di-gallic acid to act in the presence of water upon such precipitate, by gradual addition and slow digestion at a moderately-elevated temperature, until the reaction is found to be completed; substantially as described.

2. The new chemical product, a bismuth-hydroxid methylene-di-gallate, consisting of bismuth-hydroxid in chemical union with methylene-di-gallic acid, and being further characterized by a voluminous powdery form; a blue-gray color; insolubility in water; solubility in alkaline solutions with an orange color; from which solutions it is reprecipitable in its original form by acids; substantially as described.

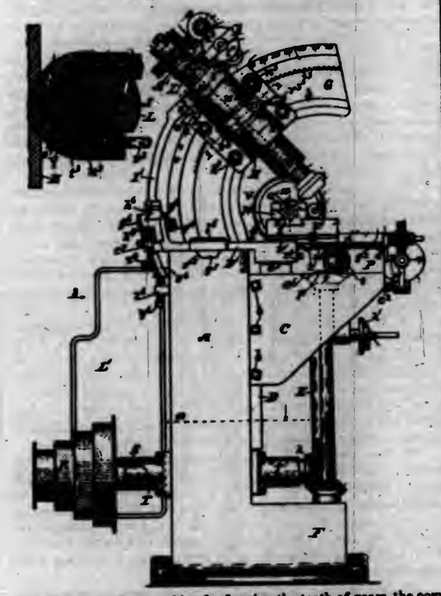
605,247. FARE-RECORDER. WILLIAM J. FORDNEY, Lancaster, Pa. Filed Aug. 11, 1897. Serial No. 647,795. (No model.)

Claim.—1. The combination, in a car-fare register, of revoluble dies having figures thereon, a presser supporting a movable ribbon and located opposite the figures, and means for actuating the presser to force the ribbon against said figures, a portion of said ribbon being exposed, whereby a name may be written on the ribbon in position to refer to the figures pressed thereon, for the purpose specified.



2. The combination, in a car-fare register, of revoluble dies having figures thereon, a presser supporting a movable ribbon and located opposite the figures, and means for actuating the presser to force the ribbon against said figures, the case of said register having a slot therein, whereby a name may be written on said ribbon and in line with the part thereof pressed against said figures, for the purpose specified.

3. The combination, in a car-fare register, of revoluble dies having figures thereon, a presser having a movable ribbon passing through the same, said presser having a slot through the back thereof and opposite said figures, guide-studs passing loosely through perforations in the presser, and means for actuating the presser to force the ribbon against said figures, the front plate of the presser having a slot therein, whereby a name may be written on the ribbon, for the purpose specified.



4. The combination, in a car-fare register, of revoluble dies having figures thereon, a presser having a slot in its back plate and opposite a line of said figures and a slot in its front plate in line with the slot in the back plate, pins passing loosely through perforations in the presser, wheels opposite the ends of the presser and provided with cam-slots having depressions formed therein toward the dies, arms on the presser and engaging said cam-slots, a roller above the dies, a roller below the dies, a ribbon being secured to the two rollers and passing loosely through a slot between the front and back plates of the presser, a gear-wheel on the lower roller, a segment of teeth on one of the cam-wheels and adapted to mesh with the teeth of the gear-wheel, and means for actuating said mechanism, all substantially as and for the purpose specified.

605,248. DISPLAY-BOX. GEORGE W. FROELICH, Chicago, Ill. Filed May 10, 1897. Serial No. 636,970. (No model.)

Claim.—A display-box in which the upright walls are bound and held by upper and lower binding-bars, each formed of a single piece of sheet metal having a base and two parallel flanges, the inner flange and base cut away at intervals that the bar may be bent upon the outer flange to conform to the shape of the box; said binding-bars being held together by angular sheet-metal cross-sections B, forming posts and feet, said box having a bottom fastened to the inner flange of lower binding-bar; and a cover bound with a single piece of sheet metal having cut flanges and hinged to the upper binding-bar.

605,249. MACHINE FOR FORMING GEAR-TEETH. JAMES H. GLEASON, Rochester, N. Y., assignor to the Gleason Tool Company, same place. Filed Feb. 23, 1897. Serial No. 624,897. (No model.)

Claim.—1. In a machine for forming the teeth of gears, the combination with a gear-blank holder, of a cutter, and means for simultaneously moving the cutter circularly and tangentially relatively to the periphery of the gear-blank, substantially as set forth.

2. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a cutter, and means for simultaneously moving the cutter circularly, tangentially, and radially, substantially as set forth.

3. In a machine for forming the teeth of gears, the combination with a gear-blank holder, of a cutter movable circularly, tangentially, and radially, and means for varying the circular movement relatively to the radial movement while the tangential movement remains the same, substantially as set forth.

4. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a cutter, and means for moving the holder axially, and means for moving the cutter circularly and tangentially relatively to the periphery of the gear-blank, substantially as set forth.

5. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a cutter, and means for moving the holder axially, and means for moving the cutter circularly, tangentially, and radially, the tangential movement being relatively to the periphery of the gear-blank and the radial movement being relatively to the circular movement, substantially as set forth.

6. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a cutter, and means for moving the cutter circularly, and tangentially, the tangential movement being relatively to the periphery of the gear-blank, substantially as set forth.

7. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a cutter, and means for moving the cutter circularly, tangentially, and radially, the tangential movement being recurrent, and the circular movement varying in extent relatively to the radial movement, substantially as set forth.

8. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a cutter, and means for simultaneously moving the cutter circularly and tangentially, and stops for limiting the amount of tangential movement, substantially as set forth.

9. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a cutter, and means for moving the cutter toward and from the holder at right angles to the point of the tooth to be cut, and means for moving the cutter circularly and tangentially relatively to the periphery of the gear-blank, substantially as set forth.

10. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a cutter, means for moving the cutter toward and from the holder at right angles to the point of the tooth to be cut, and means for moving the cutter circularly, tangentially, and radially, the tangential movement being relatively to the periphery of the gear-blank and the radial movement being relatively to the circular movement, substantially as set forth.

11. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a swinging base-block pivotally secured adjacent thereto, a cutter-support mounted upon the block and movable at a tangent to the periphery of the gear-blank, and means for simultaneously moving said block and cutter-support, substantially as set forth.

12. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a swinging base-block pivotally secured adjacent thereto, a cutter-carrier mounted upon the block and movable tangentially to the periphery of the gear-blank, and a cutter-spindle in the carrier, substantially as set forth.

13. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a swinging base-block pivotally secured adjacent thereto, a carrier mounted upon the block to move tangentially to the swinging movement of the block, a projection upon the carrier, a stem movable longitudinally through said projection, stops upon the stem, a spindle in the carrier, and means for moving said stem, substantially as set forth.

14. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a swinging base-block pivotally secured adjacent thereto, a carrier mounted upon the block, a cutter mounted on the carrier, a longitudinally-movable stem adjacent to the carrier and adapted to engage therewith, a cam-wheel adjacent to one end of the stem provided with a groove for moving the stem, said groove being provided with two throws and two dwells, substantially as set forth.

15. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a rotary cutter movable circularly, tangentially, and radially, and means for simultaneously stopping the rotary, tangential and radial movement of the cutter, substantially as set forth.

16. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a radially-movable rotary cutter, and means for rocking the holder axially at variable rates of speed, substantially as set forth.

17. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a laterally-movable cutter, an arm for locking the holder axially, and means for moving the free end of said arm at different rates of speed, substantially as set forth.

18. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a swinging base-block pivotally secured adjacent thereto, a cutter upon the base-block, an arm connected with the blank-holder, a wheel connected with the base-block for moving the arm, and means for locking the wheel against rotation during a portion of the swinging movement of the base-block, substantially as set forth.

19. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a swinging base-block pivotally secured adjacent thereto, an arm for moving the block, a wheel upon said arm, an arm connected with the blank-holder, a rack between the end of the blank-holder arm and the wheel, and means for locking the wheel against rotary movement during a portion of the swinging movement of the arm on the base-block, substantially as set forth.

20. In a machine for forming the teeth of gears, the combination with a gear-blank holder, of a base-block pivotally secured adjacent thereto, an arm for swinging the block, the free end of which is provided with a wheel, a track for the wheel, an arm connected with the blank-holder, a rack between the end of the blank-holder arm and the wheel, and arresters adjustably secured to the wheel and adapted to engage with and slide upon the track, substantially as set forth.

21. A machine for forming the teeth of gears, having a rotary cutter adapted to move sidewise in the line of the axis of its rotation, and means to give it said sidewise motion, and a feed motion for the cutter, in combination with a holder for the blank-gear, and means for rocking the latter, said sidewise motions of the cutter being timed with reference to the rocking of the gear, said motions being automatically variable relatively to each other, substantially as described.

22. A machine for forming the teeth of gears, having a rotary cutter adapted to move sidewise in the line of the axis of its rotation, and means to give it said sidewise motion, and a feed motion for the cutter, in combination with a holder for the blank-gear, and means for reciprocally swinging the cutter and for rocking the blank-gear upon its axis, the said sidewise motion of the cutter being made at the termination of each swing of the cutter, substantially as shown and described.

23. A machine for forming the teeth of gears, having a rotary cutting-tool adapted to have sidewise motion in line with the axis of its rotation, and means to give it said sidewise motion, in combination with a holder for the blank-gear to be acted upon by the cutter, and a feed motion for the cutter, and means for micrometrically adjusting or regulating the extent of said sidewise motions of the cutter, substantially as set forth.

24. A machine for forming the teeth of gears, having a cone-center, and a rotary cutter and feed mechanism therefor, in combination with a holder for the blank-gear to be cut, and means for turning said gear upon its axis, and to alternately move the cutter in parallel positions from one side to the other of a plane at right angles with the axis of the cutter and passing through the cone-center of the machine, substantially as described.

25. A machine for forming the teeth of gears, having a spindle for holding the gear to be cut, a spindle-barrel, and a holder for both spindle and spindle-barrel, in combination with a clamping-ring carried by said holder to control the spindle-barrel, and means for moving the spindle-barrel longitudinally through said holder, substantially as set forth.

26. A machine of the class described, a column, a reciprocating bar at the top of the column, a frame pivotally secured at an angle to the bar, a revolving cutter on the frame movable toward and from the pivotal point, and means for connecting the bar with the frame whereby the frame is swung upon its axis as the bar is reciprocated, substantially as set forth.

27. A machine of the class described having a prismatic column for supporting the operating parts, formed with a horizontal upper surface and with a horizontal race therein, in combination with a reciprocating bar or reciprocator occupying said race and adapted to slide therein, with means to give said bar a rectilinear reciprocal motion in the race, substantially as shown and for the purpose specified.

28. A machine of the class described, a column, a reciprocating bar at the top of the column, a frame pivotally secured adjacent to the bar, and means for connecting the bar and the frame so that when the bar is reciprocated the frame is moved upon its pivot, a revolving cutter movable toward and from the pivotal point of the frame, a gear-blank holder above the cutter, and an arm connected with the holder at one end and adjustably connected with the frame at the other, and means for simultaneously moving said bar, arm and holder, substantially as set forth.

29. A machine for forming the teeth of gears, having a circular segment mounted upon a base, and a holder for the blank-gear to be cut secured movably to said segment, a spindle-barrel in said holder, a spindle in said barrel, and a blank-gear arbor secured to said spindle, with a rack and pinion to move said holder and dependent parts along the segment, substantially as specified.

30. A machine of the class described, a gear-blank holder, a spindle therein, one end of which is provided with means for holding the gear-blank and the opposite end is provided with a worm-gear, a worm for operating said gear, a yoke secured to the holder, a toothed wheel adjustably secured in the yoke provided with as many teeth as there are teeth in the worm-gear, and a removable wheel upon the end of the worm for determining the number of teeth of the gear upon the spindle, substantially as set forth.

31. A machine of the class described, a gear-blank holder, an arm secured thereto, the free end of which is provided with a segmental gear, a segmental rack for engaging therewith, a track below the rack, a laterally-movable frame provided with a rotary cutter, and means for moving the cutter thereon, a wheel upon the frame, a portion only of the periphery of which is provided with teeth to engage with the rack, and stops adjustably secured to the wheel for limiting its rotation upon the track, substantially as set forth.

32. A gear-tooth-forming machine, having a supporting-column, a knee or bracket at one side of the column, a base-block adapted to swing upon the knee, and a cutter supported by the base-block, in combination with an oscillating arm connected with said parts upon the knee and resting upon the column, and means to reciprocate said arm and parts above the knee, substantially as shown and described.

33. A gear-tooth-forming machine having a supporting-column, a knee or bracket held by the column, a vertical shaft held by the column and the knee, a base-block upon the knee, and a cutter supported by the base-block, in combination with an oscillating arm on the column connected with the base-block, and means to reciprocate said arm and base-block around the axis of said shaft as a center, substantially as specified.

34. A machine for forming gear-teeth, having a supporting-column, a knee held by the column, a vertical geared shaft held by the column and the knee, a base-block on the knee, a horizontal geared shaft at the side of the base-block, a shaft in the base-block connecting said vertical shaft and said horizontal shaft, in combination with a cutter, and a cutter-spindle supported by the base-block, and gearing connecting said spindle and said horizontal shaft, and means to turn the vertical shaft, substantially as set forth.

35. A machine of the kind described, a column provided at its top with a segmental upright, a holder adjustably secured thereto and provided with a split sleeve, a toothed spindle-carrier in the holder, a pinion journaled in the sleeve in engagement with the carrier, and a locking-bolt through the split portion of the ring for clamping the carrier in its adjusted position, substantially as set forth.

36. A machine for forming gear-teeth, having a supporting-column, a base-block supported by the column, a carriage on the base-block for supporting a cutter, a feed-screw for the carriage, a feed-shaft to coact with the feed-screw, provided with a disk at one end, a back shaft at right angles to the axis of the disk, a friction-ring on the back shaft movable across the face of the disk, a holder for said shaft, pivoted so as to allow the shaft motion toward or from the feed-screw and the back shaft, and means for controlling said holder, substantially as described.

37. In a machine for forming the teeth of gears, a cutter-carrier, a carriage for holding the cutter-carrier, a spindle in the carrier, an internally-toothed cam free on the spindle, a pinion on the spindle to turn the cam, an intermediate gear for the pinion and the cam, a block or body actuated by the cam, a stem in the block or body occupying a place in said carriage, and stops to control said stem whereby the cam acts to move the spindle-carrier upon the carriage, substantially as and for the purpose set forth.

38. In a machine for forming gear-teeth, having a supporting-column, a movable bracket held by the column, parts for supporting a cutter resting upon the bracket and adapted to swing thereon, an oscillating arm upon the column connected with the parts supporting the cutter, means for reciprocating said arm, a segment-carrier secured to said arm, a toothed segment held by said carrier, a toothed wheel held by the carrier to engage said segment, and a track for said wheel to roll upon, substantially as and for the purpose specified.

39. In a machine for forming gear-teeth, having a supporting-column, a movable bracket held by the column, parts for supporting a cutter resting upon the bracket and adapted to swing thereon, an oscillating arm upon the column connected with the parts supporting the cutter, means for reciprocating said arm, a segment-carrier secured to said arm, a toothed segment held by said carrier, a toothed wheel held by the carrier to engage said segment, and arresters for controlling said wheel, as described.

40. In a machine for forming gear-teeth, having a supporting-column, and a rotary cutter, an oscillating arm upon the column for actuating said cutter, a segment-carrier secured to the arm, a toothed segment on said carrier, a toothed wheel held by said carrier to actuate the segment, a blank-gear spindle, and parts connecting said spindle and the toothed segment, substantially as shown and described.

41. In a machine for forming the teeth of gears, the combination, with a support, of a base-block pivotally secured thereto, a gear-blank holder above the block, a motor-shaft journaled at the pivotal point of the block, a cutter upon the block movable tangentially relatively to the periphery of the gear-blank and radially relatively to said pivotal point, and means connected with said motor-shaft for moving the cutter simultaneously in said directions in all positions of the block around its pivot, substantially as set forth.

42. In a machine for forming the teeth of gears, the combination, with a support, of a base-block pivotally secured thereto, a gear-blank holder above the block, a motor-shaft journaled at the pivotal point of the block provided with a gear-wheel, a rotary cutter upon the block, mechanism for rotating the cutter, moving it tangentially relatively to the gear-blank and moving it radially relatively to the pivotal point, a shaft for operating said mechanism the inner end of which is provided with a gear in engagement with the gear on the motor-shaft, and means for swinging the block around its pivotal point, substantially as set forth.

43. In a machine for forming the teeth of gears, the combination, with a support, of a base-block pivotally secured thereto, a motor-shaft journaled at the pivotal point of the block, a rotary cutter on the block, two parallel shafts, one of which rotates the cutter and the other one moves it radially relatively to the pivotal point of the block, mechanism for operating said shafts, and a shaft for communicating motion from said motor-shaft to said mechanism in all positions of the block around its pivotal point, substantially as set forth.

44. In a machine for forming the teeth of gears, the combination, with a support, of a base-block pivotally secured thereto, four shafts rectangularly arranged relatively to each other, one of said shafts being a feed-screw, a cutter upon one of the other shafts, a friction-disk and a friction-ring upon the other shafts, and means for operating said shafts from a common source of power, substantially as set forth.

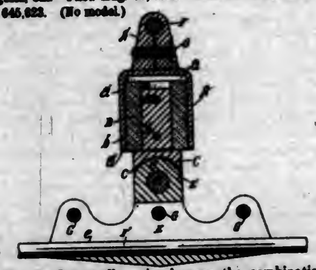
45. In a machine for forming the teeth of gears, the combination, with a gear-blank holder, of a rotary cutter provided with two oppositely-located cutting-faces, and means for automatically and reciprocatingly moving said cutter in the line of its axis between two adjacent teeth of the blank being cut, substantially as set forth.

46. In a machine for forming the teeth of gears, the combination with a gear-blank holder, of a rotary cutter provided with two oppositely-located cutting-faces, and means for reciprocatingly moving said cutter in the line of its axis simultaneously with the forward feeding movement of the cutter, substantially as set forth.

605,250. INCANDESCENT GAS-LAMP.

FERDINAND CHRISTOPH VON HEYDEBRAND UND DER LASA, New York, and JOSEPH LOCH, Brooklyn, N. Y., assignors to the Heydebrand Incandescent Light Company, New York, N. Y. Filed May 24, 1897. Serial No. 637,920. (No model.)

Claim.—1. In a gas-lamp, the combination of an apertured mixing-chamber, an apertured sleeve independent of the burner and freely movable thereon, a pin-and-slot connection between the sleeve and mixing-chamber, whereby the said sleeve may be moved longitudinally on the mixing-chamber when it is rotated thereon, and means for fixing the sleeve in a predetermined position.



2. In a gas-flow regulator, the combination of a valve-chamber having a frusto-conical valve-seat, the opening in which is at the apex thereof, a conical check-valve apertured at its sides and of a diameter sufficient to reach contact with the side walls of said valve-chamber and entered into the valve-seat of the chamber, and a stop for preventing the check-valve from contacting with the said valve-seat and closing the opening therein.

3. As a means for securing the efficient burning of the gas in a gas-burner, the combination of a mantle, and a foraminous spreader provided with apertures *t*, which apertures *t* are at different inclinations to the surface of the spreader, the apertures near the middle of the spreader being generally more inclined to the axis of the spreader than those at the edge thereof so as to spread the gas out into a sheet, whereby the gas will burn in a comparatively flat flame in the direction of the mantle.

4. In a burner of the character described, the combination with a cup provided with burner-orifices, of a flash-back pan having a central imperforate downwardly-extending dished portion surrounded by perforated rim, said pan being located within the said cup, whereby the said downwardly-extending dished portion of the pan will distribute the gas outward to the perforated rim, substantially as described.

605,251. TROLLEY-WIRE HANGER.

GEORGE E. JOHNSON, Los Angeles, Cal. Filed Aug. 19, 1896. Renewed July 22, 1897. Serial No. 645,623. (No model.)

Claim.—1. In a trolley-wire hanger, the combination set forth of an insulator; a stud fastened within said insulator, one end of the stud being formed into one-half of a hinge; a clamp for clamping upon a trolley-wire, composed of one piece with its upper portion formed into one-half of a hinge to unite with the half-hinge of the stud; a pintle for pivoting the members of the hinge together; and screws for drawing the clamp tightly upon a trolley-wire, substantially as set forth.

2. In a trolley-wire hanger, the combination set forth of a cylindrical insulator provided with suitable threads on its outside; a stud fastened within said insulator, one end of the stud being formed into one-half of a hinge; a clamp for clamping upon a trolley-wire, composed of one piece with its upper end formed into a one-half hinge for uniting with the stud; a pintle pivoting the hinge members to each other; screws for drawing the clamp tightly upon a trolley-wire; and a screw-threaded socket adapted to receive the screw-threaded plug.

3. In a trolley-wire hanger, the combination set forth of a cylindrical insulator provided with suitable threads on its outside; a stud fastened within said insulator and having its lower end formed into one-half of a hinge; a clamp for clamping upon a trolley-wire, having its upper end formed into a one-half hinge for uniting with the stud; a pintle pivoting the hinge members to each other; a screw-threaded socket adapted to receive and chamber the insulator; and means for drawing the clamp tightly upon a trolley-wire.

4. In a trolley-wire hanger, the combination set forth of an insulator; a stud fastened within said insulator by the introduction of pins through both the insulator and the stud, one end of the stud being formed into one-half of a hinge; a clamp for clamping upon a trolley-wire, composed of one piece with its upper portion formed in one-half of a hinge to unite with the half-hinge of the stud; a pintle for pivoting the members of the hinge together; and screws for drawing the clamp tightly upon a trolley-wire, substantially as set forth.

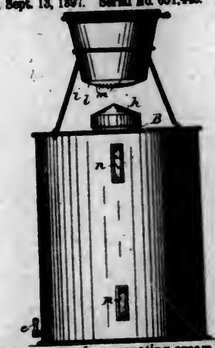
5. In a trolley-wire hanger, the combination of a cylindrical insulator with suitable threads on its outside; a stud fastened within the said insulator by the introduction of pins through both the insulator and the stud, one end of the stud being formed into one-half of a hinge; a clamp for clamping upon a trolley-wire, composed of one piece with its upper end formed into a one-half hinge for uniting with the stud; a pintle pivoting the hinge members to each other; screws for drawing the clamp tightly upon a trolley-wire; and a screw-threaded socket adapted to receive the screw-threaded plug.

6. In a trolley-wire hanger, the combination with the trolley-supporting wire, of the cap and clamp combined; the screws for clamping the clamp upon such wire; the insulating-plug; the stud; the pins passing through the stud and the plug; the clamp for clamping upon the trolley-wire; the screws for said clamp; and the pin pivoting the trolley-wire clamp to the stud.

7. In a trolley-wire hanger, the combination of an interiorly-screw-threaded cap; a plug of insulating material exteriorly screw-threaded and screwed into the cap; a trolley-wire hanger having its stud secured in the plug; the rim of the cap being beveled outward and downward away from the plug to form a drip edge.

8. In a trolley-wire hanger, the combination set forth of the interiorly-threaded cap; a plug of insulating material provided with exterior screw-threads and screwed into the cap; a trolley-wire clamp having a stud seated in the plug with its end arranged below the top of the plug; and the pins passing through the plug and the stud and

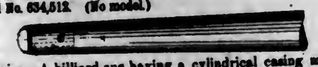
having their ends arranged at a distance from the exterior of the plug, substantially as set forth.



9. In a trolley-wire hanger, the combination of an integral cap and clamp adapted to be clamped upon a guy-wire, the cap being interiorly screw-threaded; a plug of insulating material provided with exterior screw-threads and screwed into the cap; a stud secured in the plug and having its lower end provided with one member of a hinge; a clamp adapted to clamp upon a trolley-wire and provided with the other member of a hinge; and a pintle pivoting the hinge members together.

10. In a trolley-wire hanger the combination of the cap and clamp combined D D, the insulator F, the stud G, the pins H H, the pin I, the screws E E, the screws J J J and the clamp K, all assembled together in the manner and for the purpose as specified.

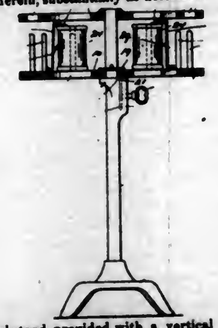
11. As means for holding a trolley-wire in the proper position in relation to a trolley-supporting wire and insulating one from the other, the combination set forth of a cylindrical insulator, with suitable threads cut upon its outside, a stud fastened within the said insulator by the introduction of suitable pins through both the insulator and the stud, with one end of the said stud formed into one-half of a hinge, a clamp for uniting with a trolley-wire composed of one piece with its upper end formed into a one-half hinge for uniting with the stud G and suitable screws for drawing the said clamp tightly upon a trolley-wire, substantially as described and for purpose as specified.



12. In a trolley-wire hanger, the combination with the trolley-supporting wire A of the cap and clamp combined D D, the screws E E, the insulator F, the stud G, the pins H H the pin I, the screws J J J and the clamp K, substantially as described.

605,252. APPARATUS FOR SEPARATING CREAM FROM MILK. CHESTER I. LEE, Elfleburg, and FREDERICK G. LEE, Pierrepont Manor N. Y. Filed Sept. 13, 1897. Serial No. 651,446. (No model.)

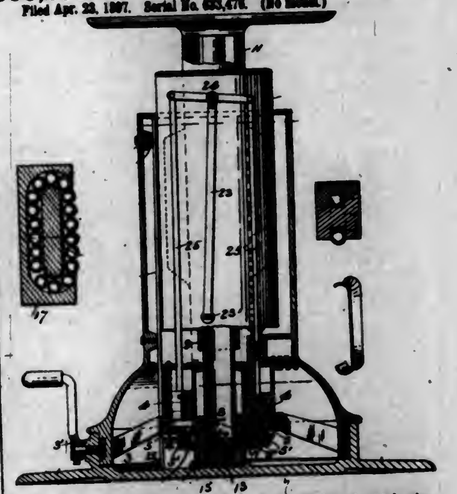
Claim.—An apparatus for separating cream from milk comprising a milk-can provided with a centrally-depressed bottom and having an outlet in the center of said bottom, a cooler within said can and provided on its bottom with feet supporting the cooler over said outlet with passages under the cooler, said feet serving to prevent eddying of the outflowing liquid and causing a draft of said liquid equally from all sides of the can to the outlet and also promoting the discharge of the sediment from the bottom of the can substantially as described.



605,253. BILLIARD CUE. FREDERICK LEU, College Point, N. Y., assignor to Felix Mainella, New York, N. Y. Filed Apr. 30, 1897. Serial No. 634,512. (No model.)

Claim.—A billiard-cue having a cylindrical casing mounted in the end thereof and an aperture in the side thereof, said casing having a tapering channel leading therethrough, and an aperture in the side thereof registering with the apertures in the cue, in combination with a removable tip having a tapering pin extended therefrom for engagement with said channel, and the apertures in the casing and cue adapted to admit the entrance of an instrument beneath the pin, substantially as shown and described.

605,254. SPOOL-STAND. THOMAS MASON, New York, N. Y. Filed June 21, 1897. Serial No. 641,695. (No model.)



Claim.—1. In a spool-stand, the combination of a base, an upright standard, a revoluble plate mounted thereon, upwardly-directed pins supported by said plate, an upper disk or plate mounted on said standard above said revoluble plate and having an opening through which spools of thread may be passed and means for locking said revoluble plate in position, said upper plate being in such relation to the top of said pins as to prevent the removal of a spool except through said openings therein, substantially as described.

2. A spool-stand provided with a vertical standard having a shoulder formed thereon, a plate or disk revolubly mounted on said shoulder and standard having a socket therein adjacent to said standard, and provided with vertical pins adapted to receive spools another disk or plate secured to the top of said standard and provided with an opening through which the spools may be placed upon said standards, and a lock mounted in said shoulder and the bolt of which is adapted to enter the socket in said plate, substantially as and for the purpose described.

3. A spool-stand provided with a vertical standard, a revoluble disk or plate mounted thereon, and provided with vertical pins which are adapted to receive spools, another disk or plate secured to the top of said standard above said pins, and provided with an opening through which the spools may be inserted, and means for locking the lower disk or plate in position on said standard, the bottom disk or plate being also provided with spring-arms, the upper ends of which overlap the ends of the spools, and said spring-arms being provided with holes or openings through which the thread is passed, said upper plate being in such relation to the top of said pins as to prevent the removal of a spool, substantially as shown and described.

605,255. DENTAL CHAIR. MONT C. MERKEL, Philadelphia, Pa. Filed Apr. 22, 1897. Serial No. 633,478. (No model.)

Claim.—1. The combination of the pedestal, the tube 11 having a flattened exterior surface to provide a bearing for two laterally-adjacent series of balls, and the pedestal extension-tube, said pedestal extension-tube having channels provided with antifriction-balls adapted to bear on the tube 11 and mediately on the pedestal, substantially as described.

2. The combination of the pedestal, the tube 11, and the pedestal extension-tube, said latter tube having channels provided with antifriction-balls adapted to bear on said tube 11 and mediately on the pedestal, and with adjustable bearing-plates for the balls intermediate the pedestal and its movable extension, substantially as described.

3. The combination of the pedestal, the tube 11, and the pedestal extension-tube, said latter tube having channels provided with antifriction-balls adapted to bear on tube 11 and mediately on the pedestal, and with adjustable bearing-plates for the balls intermediate the pedestal and its movable extension, one of the plates being made wide to furnish a bearing for two laterally-adjacent series of balls, substantially as described.

4. The combination of the pedestal provided with interior tracks for antifriction devices, the seat-tube 11 supporting the chair-seat, the pedestal extension-tube intermediate the pedestal and seat-tube, antifriction-balls carried by said pedestal extension, said balls situated near the top and bottom of the extension-tube being oppositely situated and bearing respectively on tube 11 and on the pedestal-tracks, and the oil-reservoir situated in the path of the extension-tube, substantially as described.

5. In a dental chair, the combination of tubes to hold a liquid column for the raising and lowering of a seat, a pump to force liquid into said tubes, a lever having a fulcrum supported by the pedestal and connected to the pump-piston, a lever having a fulcrum in the pedestal-wall with one arm extended outside thereof and provided with an operating-crank, the other arm of said lever being situated within the pedestal and slotted, a lever having a fulcrum in the pedestal-wall below and adjacent the slotted lever and provided with a pin situated in the slot of said slotted lever the arm of said lever with a pin being extended below its pin and loosely connected to the first-named lever, substantially as described.

6. In a dental chair, a supplemental seat-frame pivoted to the main seat-frame and adapted to support a supplemental seat above the main seat or to fold down within the foot-rest frame, substantially as described.

7. In a dental chair, a supplemental seat-frame pivoted to the main seat-frame and adapted to support a supplemental seat above the main seat or to fold down within the foot-rest frame, and a supplemental foot-rest pivoted to the supplemental seat-frame, substantially as described.

8. In a dental chair, a supplemental seat-frame pivoted to the main seat-frame and adapted to support a supplemental seat above the main seat or to fold down within the foot-rest frame, a supplemental foot-rest pivoted to the supplemental seat-frame, said supplemental foot-rest being adapted to be folded when the supplemental seat-frame is turned down and between the two frames, substantially as described.

9. A dental chair having a main seat-frame and a supplemental seat-frame, a detachable arm-rest, said rest and frames being provided with means whereby the rest may be connected to either seat-frame, substantially as described.

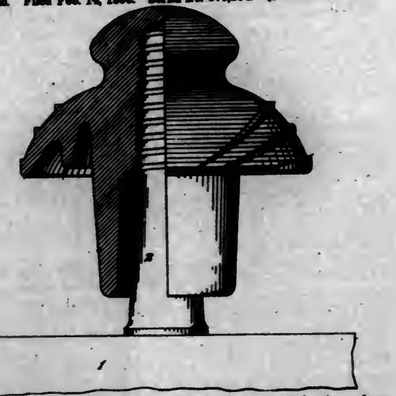
10. In a head-rest support, the ball of the ball-and-socket joint provided with an arm and ring the latter having an angular opening, the rod provided with an angular part intermediate its ends to movably fit the said angular opening, pad-supports having rings embracing said rod, and means for locking said rings together, the ball-arm ring being situated between said locking-rings, substantially as described.

11. In a head-rest the head-supporting pads provided with several arms movably held on a rod and the arm extending from the ball of a ball-and-socket joint, said rod and arm being rigidly connected circumferentially and loosely connected lengthwise the rod at a point near its center and means for fastening the arms together, substantially as described.

12. In a dental chair, the combination of the approximately cylindrical pedestal provided with a lateral enlargement 24′ having relatively long and short sides 24″ and 24‴, one side being approximately tangential to the main body of the pedestal-wall, the pumps situated partly in the recess formed in the enlargement and adjacent said latter side, and the two-armed lever having a fulcrum in said side and movable parallel therewith, substantially as described.

13. The combination of telescoping tubes and means for moving a tube or tubes by fluid-pressure to extend them with a device for displacing a part of the fluid in the larger tube or tubes, substantially as described.

14. The combination of telescoping tubes and means for moving a tube or tubes by fluid-pressure to extend them with a device for displacing a part of the fluid in a larger tube or tubes, said device being attached to and movable with a tube, substantially as described.



15. The combination with telescoping tubes and means for moving a tube or tubes by fluid-pressure to extend them of a fluid-displacing plunger situated in the larger tube, said means for producing the pressure comprising one or more pumps and a compound lever to operate the same, substantially as described.

16. In combination the base having a flange 3′ constituting with said base an oil-reservoir and having integral with its bottom an annular closed seat 13′, the casting 13 rotatable in said seat and having pump-ports, a pump and tube 8 supported in said casting and the latter having an extension fixed to the pedestal whereby the casting supports the tube and pumps and moves with the pedestal, substantially as described.

17. The compound lever having a pivoted member 29, and a pivoted member 26, said members being loosely connected and each provided with a separate pivot or fulcrum, and a lever 23 having a fulcrum 24 and loosely connected to the lever 26 intermediate said levers 23 and 29, substantially as described.

18. In combination with a separable casting having an opening in its bottom and interior conduits, with inlet and outlet valve seats for a pump-cylinder, one of said seats being immediately over the said opening, an upwardly-closing valve provided with a stem and a removable plug having a larger diameter than the valve situated in the bottom of the casting immediately below the valve, said plug having a socket with closed bottom to receive the end of the valve-stem, substantially as described.

605,256. INSULATOR. RALPH D. MERSHON, Colorado Springs, Colo. Filed Feb. 14, 1898. Serial No. 670,204. (No model.)

Claim.—1. An insulator for high-tension circuits having a long, tubular petticoat adjacent to the supporting-pin and a short outer petticoat of much greater diameter the edge of which is approximately the same striking distance from the cross-arm and the supporting-pin.

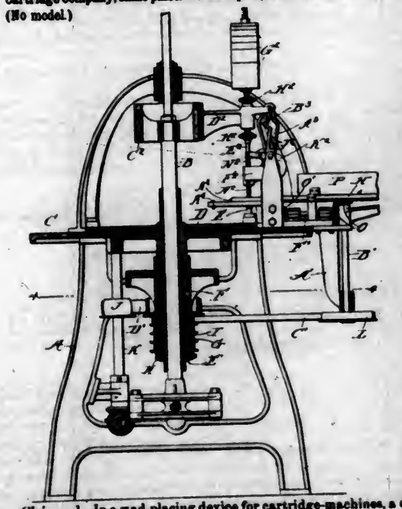
2. An insulator for high-tension circuits having two or more ridges on its outer surface which extend transversely to the cross-arm, a long, tubular petticoat adjacent to the supporting-pin and an outer petticoat of much greater diameter the edge of which is approximately the same striking distance from the supporting-pin and the cross-arm.

3. An insulator for high-tension circuits having outer ridges transverse to the cross-arm, a long tubular petticoat adjacent to the supporting-pin and a plurality of short petticoats, the outer one of which has a much greater diameter than the long petticoat and is approximately the same striking distance from the supporting-pin and the cross-arm.

605,257. TUBE-CUTTER. JEREMIAH MILLER, Cleveland, Ohio. Filed Mar. 31, 1897. Serial No. 630,069. (No model.)

Claim.—1. A tube-cutter comprising in combination a tubular body having a reduced neck and a number of radiating channels extending through the body intermediate of its length, cutters seated in said channels and having radial movement therein, springs pressing said cutters inward, a gage revolubly fitting on the neck, a sliding collar fitting on the neck and having a binding-screw, and a tapering wedge having peripheral flat faces engaging and actuating each of the cutters and adapted to be turned to rotate the apparatus, substantially as described.

2. In a tube-cutter the combination of a tubular body having a neck of less diameter with external flat faces, and having intermediate radial channels extending through the body-wall, cutters fitting said channels and movable radially therein, annular flat springs seated in grooves on the cutter-body and pressing the cutters inward, a gage revolubly fitting on said neck, a sliding collar fitting on said neck and having a binding-screw, and a tapering wedge having peripheral flat faces engaging the cutters and adapted to be turned to rotate the apparatus, substantially as described.



3. In a tube-cutter the combination of a tubular body having a neck of less diameter with external flat faces, and having intermediate radial channels extending through the body-wall, cutters fitting said channels and movable radially therein, annular flat springs seated in grooves on the cutter-body and pressing the cutters inward, a gage revolubly fitting on said neck and having forward-extending arms, a sliding collar fitting on said neck and having a binding-screw, and a tapering wedge having peripheral flat faces engaging the cutters and adapted to be turned to rotate the apparatus, substantially as described.

4. A tube-cutter comprising in combination a tubular body having a neck of less diameter, a number of radiating channels extending through the solid body-wall intermediate of its length, cutter-cages fitting said channels and movable radially therein, rotary cutters journaled in said cages, springs seated in grooves on the cutter-body and pressing said cutters inward, a gage revolubly fitting on said neck, a sliding collar fitting on said neck and having a binding-screw, and a tapering wedge having peripheral flat faces engaging the cutter-cages and adapted to be turned to rotate the apparatus, substantially as described.

5. In a tube-cutter the combination of a tubular body or barrel transversely grooved externally and having intermediate radial channels extending through its body-wall, cutters fitting said channels and movable radially therein, said cutters having external shoulders and flat axially-inclined inner faces, flat annular springs seated in the grooves on said barrel and bearing on the shoulders of the cutters, and a tapering wedge having flat peripheral faces engaging each of the cutters and adapted to be turned to rotate the apparatus in the tube, substantially as described.

6. In a tube-cutter the combination of a tubular body or barrel transversely grooved externally and having intermediate radial channels extending through its body-wall, cutters having external shoulders and an intermediate cutting edge and flat axially-inclined inner faces, flat annular springs seated in the grooves on said barrel and bearing on the shoulders of the cutters, a revolubie gage and a clamping-collar fitting on the barrel, and a tapering wedge having flat peripheral faces engaging each of the cutters and adapted to be turned to rotate the apparatus in the tube, substantially as described.

605,258. WAD-PLACING MECHANISM FOR CARTRIDGE-MACHINES. GRANSON M. PETERS, Cincinnati, Ohio, assignor to the Peters Cartridge Company, same place. Filed Apr. 5, 1897. Serial No. 630,750. (No model.)

Claim.—1. In a wad-placing device for cartridge-machines, a distributing-disk and a feeding-disk, said disks arranged in substantially the same horizontal plane, the wads to be distributed and fed adapted to rest upon the top surface of the said disks, and to be delivered from the top surface of said distributing-disk to that of the feeding-disk, and means for actuating said disks; as and for the purpose set forth.

2. In a wad-placing device for cartridge-machines, a distributing-disk and a feeding-disk, the supporting-surfaces of said disks arranged in substantially the same horizontal plane, the wads to be distributed and fed adapted to rest upon said surfaces, and means for rotating said disks in opposite directions, whereby the wads are delivered from the top surface of said distributing-disk to the top surface of said feeding-disk, as and for the purpose set forth.

3. In a wad-placing device for cartridge-machines, a hopper, a disk arranged to form the bottom of said hopper and adapted to support upon the top surface thereof the wads to be distributed, and a feeding-disk arranged adjacent to and in substantially the same horizontal plane with the said first-mentioned disk and adapted to receive on the top surface thereof the wads from said feeding-disk, and means for rotating said disks in opposite directions, as and for the purpose set forth.

4. In a machine of the class described, a hopper, a channel or guideway, a disk forming the bottom of said hopper and channel, a gate or opening communicating between said hopper and channel, in combination with a wad-feeding disk arranged to receive upon the top surface thereof the wads from the said first-mentioned disk and means for rotating said disks, as and for the purpose set forth.

5. In a machine of the class described, a hopper, a channel or guideway, a gate or opening communicating between said hopper and channel, means for adjusting the area of said opening, in combination with a disk forming the bottom of said hopper and channel, and means for rotating said disk, as and for the purpose set forth.

6. In a machine of the class described, a hopper, a channel, an opening formed in said hopper and communicating with said channel, a top plate or guard for said channel, and means for adjusting the same, in combination with a distributing-disk forming the bottom of said hopper and channel, and means for rotating said disk, as and for the purpose set forth.

7. In a machine of the class described, a stationary flange, a stationary hopper arranged within said flange and concentric therewith, said flange and hopper forming the side walls of a channel, a gate forming a communication between said hopper and channel, a disk arranged to form a bottom for said hopper and channel in combination with a wad-feeding disk arranged to receive upon the top surface thereof the wads from the said first-mentioned disk and means for rotating said disks, as and for the purpose set forth.

8. In a machine of the class described, a stationary flange, a stationary hopper arranged within said flange forming a channel therewith, said hopper provided with a gate opening communication between said hopper and channel, a disk arranged to form a bottom for said hopper and channel, and a second disk arranged adjacent to said first-mentioned disk and upon the top surface of which said channel delivers, and means for rotating said disks, as and for the purpose set forth.

9. In a machine of the class described, a circular distributing-disk, a stationary flange arranged to conform to the curvature of said disk, a hopper arranged within said flange and in conjunction therewith forming a channel, said hopper provided with a gate opening communication between said channel and the interior of said hopper, said distributing-disk arranged to form a bottom for said hopper and channel, an adjustable top or guard for said channel, a feeding-disk arranged adjacent to said distributing-disk and upon which said channel delivers, and means for rotating said disks in opposite directions, as and for the purpose set forth.

10. In a machine of the class described, a guideway for the wads, means for feeding the wads through said guideway, a top guard for said guideway, whereby said wads are fed singly and in single column, and means for adjusting said top guard to accommodate wads of different thicknesses, as and for the purpose set forth.

11. In a machine of the class described, a distributing-disk, and a feed-disk, in combination with devices for placing the wads, and devices for inserting the wads in the shells, as and for the purpose set forth.

12. In a machine of the class described, the combination with means for feeding the shells, of a wad-distributing disk, a wad-feeding disk, means for receiving the wads and placing the same in position to be inserted in the shells, means for inserting the wads in the shells, and means for actuating said several devices, as and for the purpose set forth.

13. In a wad-placing device for cartridge-machines, the combination with a feed-disk, a distributing-disk for delivering the wads thereto and means for actuating the same, of a wad-placing device comprising a pair of jaws, adapted to receive therebetween the wads singly from such feed-disk, and means for actuating said jaws, as and for the purpose set forth.

14. In a wad-placing device for cartridge-machines, the combination with a feedway or channel, a feed-disk arranged to form the bottom of said feedway or channel, means for automatically delivering the wads upon said feed-disks and means for rotating said disk, of a wad-placing device comprising a pair of jaws arranged to reciprocate transversely of the delivery end of such channel, and adapted to receive the wads therebetween, and means for reciprocating said jaws, as and for the purpose set forth.

15. In a wad-placing device for cartridge-machines, the combination with means for feeding the wads singly and in single column, of a placing mechanism, including a pair of clamping-jaws yieldingly coupled together, a stop for one of said jaws, and means for reciprocating said jaws, as and for the purpose set forth.

16. In a wad-placing device for cartridge-machines, the combination with means for feeding the wads singly and in single column, of a guideway arranged transverse to the line of feed of the wads, a pair of clamping-jaws arranged to operate therein, a yielding connection between said jaws whereby they are moved in unison but are permitted to yieldingly separate, a stop for one of said jaws adapted to engage a stationary part, and means for reciprocating said jaws, as and for the purpose set forth.

17. In a wad-placing device for cartridge-machines, the combination with means for feeding the wads singly and in single file, a guideway arranged transversely to the line of feed of the wads, clamping-jaws mounted to reciprocate in said guideway, a link connected to one of said jaws, a spring interposed between said link and the other of said jaws, a stop for one of said jaws, and means for reciprocating said jaws, as and for the purpose set forth.

18. In a wad-placing device for cartridge-machines, the combination with means for feeding the wads singly and in single file, a guideway arranged transverse to the line of feed of the wads, clamping-jaws mounted to reciprocate in said guideway, a link pivoted to one of said jaws, and carrying a threaded rod, a spring arranged on said rod and adapted to bear against a lug on the other of said jaws, means for regulating the tension of said spring, a stop carried by said last-mentioned jaw, and means for reciprocating said jaws, as and for the purpose set forth.

19. In a machine of the class described, a distributing-disk and an adjacent, oppositely-moving feeding-disk, and a placing mechanism in combination with a guideway for receiving the wads singly from the distributing-disk and extending to and across the feeding-disk, and delivering to the placing mechanism, as and for the purpose set forth.

20. In a wad-placing device for cartridge-machines, clamping-jaws, a slotted lever pivotally mounted and connected to said jaws, the slot in said lever being cam-shaped, a reciprocating head, means carried thereby and adapted to ride in said cam-slot whereby said lever is rocked, a stop for said jaws, and a spring mounted to act on said lever and normally acting to press said jaws against said stop, whereby lost motion is taken up, as and for the purpose set forth.

21. In a wad-placing device for cartridge-machines, a stationarily-held tube, having the upper end thereof slightly flared, clamping-jaws arranged to transport and hold the wads in alinement with said tube and a rammer arranged to force the wads from said pivot and through said tube, in combination with means for presenting the shells in longitudinal alinement with said tube, as and for the purpose set forth

22 In a wad-placing device for cartridge-machines, a stationarily-held tube, having the upper end thereof flared, means for placing and holding the wads in line with the tube and over the upper flared end thereof, a rammer arranged in line with said tube, means for actuating the same to force the wads through said tube, and means for presenting the shells in line with said tube, as and for the purpose set forth.

23. In a machine of the class described, means for placing and inserting the wads in cartridge-shells, in combination with a movable cap arranged to slip over the end of a shell during the operation of said inserting means whereby the shell is rounded up and steadied, as and for the purpose set forth.

24. In a machine of the class described, wad placing and inserting devices, means for actuating the same, and means for presenting the shells to said devices, in combination with means for rounding up a shell and maintaining the same in alinement with the inserting devices, comprising a movable cap, and means for slipping the same over the shell preparatory to the introduction of the wads thereto, as and for the purpose set forth.

25. In a machine of the class described, wad placing and inserting devices and shell-feeding mechanism, in combination with a perforated cap arranged to be slipped over the end of the shell during the operation of the inserting mechanism, whereby the shell is rounded up and maintained in proper alinement and means for actuating said cap, as and for the purpose set forth.

26. In a machine of the class described, wad placing and inserting devices, and shell-feeding mechanism, in combination with a perforated cap-plate, the lower mouth of said cap-plate being flared, and means for slipping said cap over the shell during the action of the inserting mechanism, as and for the purpose set forth.

27. In a machine of the class described, wad placing and inserting devices, and shell-feeding mechanism, in combination with an alining-cap, and means for depressing said cap upon the shell during the operation of the inserting devices, as and for the purpose set forth.

28. In a machine of the class described, an alining-cap, means normally acting to maintain said cap elevated above the path of feed of the shell, and means for depressing said cap, as and for the purpose set forth.

29. In a machine of the class described, an alining-cap, a lever, connected to said cap, a spring arranged to act on said lever and normally operating to maintain said cap elevated, and means for rocking said lever to depress said cap, as and for the purpose set forth.

30. In a machine of the class described, an alining-cap for the shells, reciprocating rods carrying said cap, a pivotally-mounted lever connected to said rods, and means for actuating said lever, as and for the purpose set forth.

31. In a machine of the class described, an alining-cap for the shells, rods upon which said cap is mounted, a bell-crank lever, having one arm connected to said rods and the other arm thereof provided with a cam-slot, a reciprocating head and means carried thereby for engaging said cam-slot, whereby said cap-plate is actuated, as and for the purpose set forth.

32. In a machine of the class described, a framework, a reciprocating head mounted therein, a bearing formed in said head, a rammer mounted to slide loosely through said bearing, a removable weight mounted on said rammer, and a guide formed in said framework for said rammer, as and for the purpose set forth.

33. In a machine of the class described, a framework, a reciprocating head mounted therein, a bearing formed in said head, a rammer loosely mounted to slide in said bearing, a series of removable weights mounted on said rammer, and a guide for said rammer formed in said framework, as and for the purpose set forth.

34. In a machine of the class described, a framework, a reciprocating head mounted therein, a bearing formed in said head, a rammer loosely mounted to slide in said bearing, a plurality of variously-sized weights removably mounted on said rammer, and a guide formed in said framework for said rammer, as and for the purpose set forth.

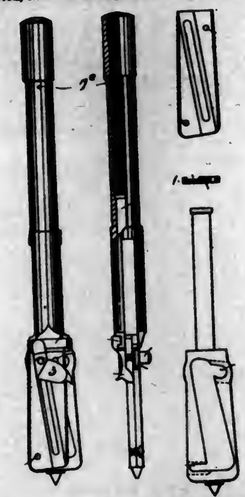
35. In a machine of the class described, a reciprocating head, a bearing formed therein, a rammer loosely mounted to slide in said bearing, a weight carried by said rammer and means for adjustably regulating the amount of the relative movement of said rammer and head, as and for the purpose set forth.

36. In a machine of the class described, a reciprocating head, a bearing formed therein, a rammer loosely mounted to slide in said bearing, an adjustable weight mounted on said rammer, and a check-nut arranged to adjustably regulate the relative movement of said rammer and head, as and for the purpose set forth.

37. In a machine of the class described, a reciprocating head, having a bearing therein, a rammer mounted to slide in said bearing, check-nuts carried by said rammer above and below said bearing, and removable weights carried by said rammer, as and for the purpose set forth.

38. In a wad-placing device for cartridge-machines, a table for feeding the shells, a series of wad distributing and wad-feeding disks arranged around the periphery of said table, a pulley, means for driving said pulley, and belt connections from said pulley for actuating said several wad distributing and feeding disks, as and for the purpose set forth.

39. In a wad-placing device for cartridge-machines, a table having an extension and adapted to support and feed the shells, wad distributing and feeding disks mounted on each extension, a pulley mounted on said extension, means for driving said pulley, and means driven by said pulley for actuating said wad distributing and feeding disks, as and for the purpose set forth.



40. In a machine of the class described, a wad-distributing disk, a wad-feeding disk, a channel arranged to extend from one of said disks to the other and adapted to contain and feed the wads singly and in single file, wad-placing jaws, a rammer, a guiding-tube, an alining-cap, a shell-case-feeding table, and means for actuating said several devices, all combined and arranged as and for the purpose set forth.

41. In a machine of the class described, two oppositely-rotating disks arranged adjacent to each other, and in substantially the same horizontal plane and a guideway arranged to extend over the surface of both disks, as and for the purpose set forth.

42. In a machine of the class described, two oppositely-rotating disks arranged adjacent to each other, and in substantially the same horizontal plane and a guideway arranged to extend over the surface of both disks, and conforming to the direction of rotation of said disks, as and for the purpose set forth.

43. In a machine of the class described, a framework, a reciprocating head mounted therein, a bearing formed in said head, a rammer loosely mounted to slide in said bearing and a plurality of variously-sized weights removably mounted on said rammer, as and for the purpose set forth.

605,259. TOOL FOR BORING CONICAL HOLES. LOUIS F. C. RIEM, Cheltenham, England, assignor to himself and JOHN HENRY HALL, New York, N. Y. Filed Sept. 27, 1897. Serial No. 653,110. (No model.)

Claim.—1. An auger comprising a spindle or rod provided near its lower end with a guide-surface or guide-surfaces inclined to the axis of the said spindle or rod, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, a cutter or cutters attached to the lower end of the said holder, means for keeping the said cutter or cutters to the said guide-surface or guide-surfaces, and a spring adapted to force apart the upper ends of the said spindle or rod and the said holder, substantially as and for the purpose set forth.

2. An auger comprising a spindle or rod provided near its lower end with a guide-surface or guide-surfaces inclined to the axis of the said spindle or rod, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, a cutter or cutters attached to the lower end of the said holder, means for keeping the said cutter or cutters to the said guide-surface or guide-surfaces, a spring adapted to force apart the upper ends of the said spindle or rod and the said holder, and means for limiting the downward movement of the said holder on the said spindle or rod, substantially as and for the purpose set forth.

3. An auger comprising a spindle or rod provided near its lower end with a guide-surface or guide-surfaces inclined to the axis of the said spindle or rod, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, a cutter or cutters attached to the lower end of the said holder, means for keeping the said cutter or cutters to the said guide-surface or guide-surfaces, a spring adapted to force apart the upper ends of the said spindle or rod and the said holder, and means for limiting the separation produced by the said spring, substantially as and for the purpose set forth.

4. An auger comprising a spindle or rod provided near its lower end with a guide-surface or guide-surfaces inclined to the axis of the said spindle or rod, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, a cutter or cutters attached to the lower end of the said holder, means for keeping the said cutter or cutters to the said guide-surface or guide-surfaces, a spring adapted to force apart the upper ends of the said spindle or rod and the said holder, and a screw inserted in the upper end of the said spindle or rod and having a head adapted to bear against a shoulder on the said holder, substantially as and for the purpose set forth.

5. An auger comprising a spindle or rod provided near its lower end with a guide-surface or guide-surfaces inclined to the axis of the said spindle or rod, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, a cutter or cutters attached to the lower end of the said holder, means for keeping the said cutter or cutters to the said guide-surface or guide-surfaces, a spring adapted to force apart the upper ends of the said spindle or rod and the said holder, and an adjustable stop for limiting the downward movement of the said holder on the said spindle or rod, substantially as and for the purpose set forth.

6. An auger comprising a spindle or rod provided near its lower end with a guide-surface or guide-surfaces inclined to the axis of the said spindle or rod, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, a cutter or cutters attached to the lower end of the said holder, means for keeping the said cutter or cutters to the said guide-surface or guide-surfaces, a screw-plug closing the upper end of the said holder, adjustable longitudinally therein, and carrying a downwardly-projecting spindle, and a spring surrounding the said downwardly-projecting spindle and pressing with its upper end against the said screw-plug and with its lower end against the said spindle or rod, substantially as and for the purpose set forth.

7. An auger comprising a spindle or rod provided near its lower end with a guide-surface or guide-surfaces inclined to the axis of the said spindle or rod, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, a cutter or cutters provided or each provided with a projection that engages in a transverse groove in the lower end of the said holder, and means for keeping the said cutter or cutters to the said guide-surface or guide-surfaces, substantially as and for the purpose set forth.

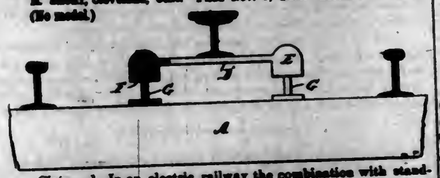
8. An auger comprising a spindle or rod, a guide-surface near the lower end of the said spindle or rod and inclined to the axis thereof, means for varying the inclination of the said surface to the said axis, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, a cutter provided with a projection that engages in a transverse groove in the lower end of the said holder, and means for keeping the said cutter to the said guide-surface, substantially as and for the purpose set forth.

9. An auger comprising a spindle or rod, a guide-surface near the lower end of the said spindle or rod and inclined to the axis thereof, means for varying the distance of the upper end of the said guide-surface from the said axis, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, a cutter provided with a projection that engages in a transverse groove in the lower end of the said holder, and means for keeping the said cutter to the said guide-surface, substantially as and for the purpose set forth.

10. An auger comprising a spindle or rod, a guide-piece attached thereto near the lower end thereof, a guide-plate which is provided with a guide-groove inclined to the axis of the said spindle or rod and is secured to the said guide-piece at its upper or lower end by means of a set-screw passing through a transverse slot in one of them and fitting a hole in the other, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, and a cutter secured in the said guide-groove, capable of being slid longitudinally therein, and provided with a projection that engages in a transverse groove in the lower end of the said holder, substantially as and for the purpose set forth.

11. An auger comprising a spindle or rod, a guide-piece attached thereto near the lower end thereof, a guide-plate which is provided with a guide-groove inclined to the axis of the said spindle or rod and is secured at both ends to the said guide-piece by means of a set-screw passing through a transverse slot in one of them and fitting a hole in the other, a tubular holder mounted on the said spindle or rod and capable of being slid longitudinally thereon, and a cutter secured in the said guide-groove, capable of being slid longitudinally therein, and provided with a projection that engages in a transverse groove in the lower end of the said holder, substantially as and for the purpose set forth.

605,260. MOUNTING FOR THIRD RAILS. SIDNEY H. SHORT, Cleveland, Ohio. Filed Nov. 5, 1897. Serial No. 657,510. (No model.)



Claim.—1. In a mounting for third or contact rails, the combination with standards, a bar supported by but insulated from said standards, an insulating strip or board supported by said bars and arranged to extend lengthwise with respect to the third or contact rail, said rail being arranged to rest on said strip or board, as and for the purpose set forth.

2. A supporting-bar for a third or contact rail having ball or cup shaped castings at the end thereof, insulating material arranged in said castings, and supporting-standards arranged to be received in said insulating material, as and for the purpose set forth.

3. A supporting-bar for a third or contact rail having inverted-ball or cup shaped castings arranged to project from the ends and on the same side thereof, insulating material arranged in said castings, and supporting-standards arranged to be received in said insulating material, as and for the purpose set forth.

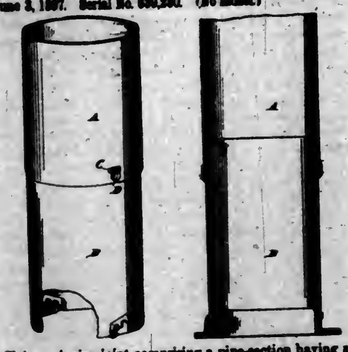
4. The combination with a third or contact rail, a supporting-bar therefor having inverted-ball or cup shaped castings arranged to project from the ends and on the same side thereof, insulating material arranged in said castings, supporting-standards arranged to be received in said insulating material, and an insulating-strip interposed between said bar and rail, as and for the purpose set forth.

605,261. THIRD RAIL FOR ELECTRIC RAILWAYS. SIDNEY H. SHORT, Cleveland, Ohio. Filed Nov. 5, 1897. Serial No. 657,511. (No model.)

Claim.—1. In an electric railway the combination with standards, a bar supported by but insulated from said standards, a third or contact rail supported upon said bar, said rail presenting a side surface for contact with the shoe or collector, and a strip or plate laid lengthwise upon said rail and extending over the top edges thereof, as and for the purpose set forth.

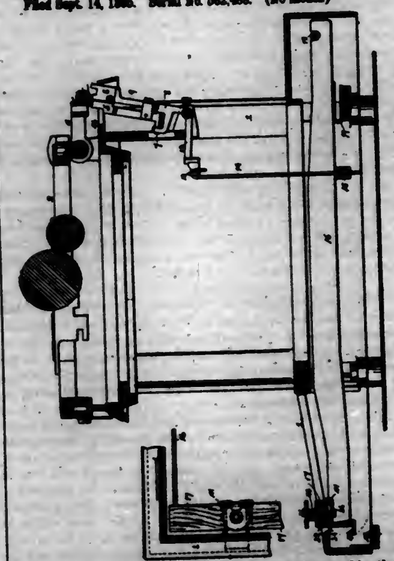
2. In an electric railway the combination with standards, a bar supported by but insulated from said standards, a third or contact rail supported upon said bar, said rail provided with a channel or groove in the side thereof extending lengthwise of said rail, and an insulating-plate resting upon the top of said rail, said insulating-plate extending lengthwise of said rail and being of a width greater than that of the rail whereby its edges project over the edges of the rail and form a protecting-cap therefor, as and for the purpose set forth.

3. In an electric railway the combination with standards, a bar carrying inverted-cup-shaped castings at the ends thereof, said castings adapted to be filled with insulation, said standards arranged to project into said castings and to be embedded in the insulation contained therein, a third or contact rail supported by said bar, said rail presenting a side surface for contact with the shoe or collector, and a plate of insulation wider than said rail, said plate resting upon the top surface of said rail and extending lengthwise thereof, thereby forming a protecting-cap for said rail, as and for the purpose set forth.



605,262. MEANS FOR FASTENING NECKTIES AND COLLARS TO SHIRTS. CHRISTOPHER H. SUPP, Brooklyn, N. Y. Filed Oct. 8, 1897. Serial No. 654,886. (No model.)

Claim.—1. The herein-described means for securing a collar and a necktie to the neckband of a shirt or shirt-front; said means consisting of inwardly-directed loops formed on or secured to the collar, outwardly-directed loops formed on or secured to the neckband, and inwardly-directed loops formed on or secured to the necktie which are passed inwardly through the collar, and an open spring-ring which is passed through said loops, substantially as shown and described.



2. The herein-described means for securing a collar and a necktie to the neckband of a shirt or shirt-front; said means consisting of inwardly-directed loops formed on or secured to the collar, outwardly-directed loops formed on or secured to the neckband, and inwardly-directed loops formed on or secured to the necktie which are passed inwardly through the collar, and an open spring-ring which is passed through said loops, means attached to the respective ends of said ring whereby they may be detachably connected, substantially as shown and described.

605,268. STOVEPIPE-JOINT. FRANK THARP, Elkin, N. C. Filed June 3, 1897. Serial No. 639,280. (No model.)

Claim.—A pipe-joint comprising a pipe-section having a tongue cut therefrom, and an overlapping section provided with a slot having one of its walls bent inward to permit the entrance of said tongue in the longitudinal movement of the pipe-sections; substantially as specified.

605,264. TYPE-WRITING MACHINE. GEORGE B. WEBB, New York, N. Y., assignor to The Wyckoff, Seamans & Benedict, same place. Filed Sept. 14, 1895. Serial No. 562,468. (No model.)

Claim.—1. In a type-writing machine, the combination of a power-driven carriage having a feed-rack and also one or more column-stops, a feed-dog normally in engagement with said feed-rack to effect step-by-step feeding movements to the carriage, and a column-stop dog directly attached to said feed-dog and moving always therewith and adapted to engage a column-stop when the said feed-dog is moved out of engagement with the feed-rack; substantially as described.

2. In a type-writing machine, the combination of a power-driven paper-carriage having a feed-rack and also one or more column-stops, a vibratory feed-dog mounted in the framework and carrying a column-stop dog adapted to cooperate with the column stop or stops when the feed-dog is vibrated out of engagement with the feed-rack; substantially as described.

3. In a type-writing machine, the combination of a power-driven paper-carriage having a feed-rack and also one or more column-stops, a feed-dog holder or rock-er pivotally mounted in the framework and carrying a feed-dog and also a column-stop dog adapted to act when the feeding devices are separated; substantially as described.

4. In a type-writing machine, the combination of a power-driven paper-carriage having a feed-rack and also one or more column-stops, the feed-dogs 5 and 6 and the column-stop dog 30 attached to the latter and adapted to act when the feeding devices are separated.

5. In a type-writing machine, the combination of a power-driven paper-carriage having a feed-rack and also one or more column-stops, the point or points of which are arranged above the plane of the points of the teeth of the feed-rack, a vibratory feed-dog and a column-stop dog attached to the latter to move therewith and projecting above or beyond the end of said feed-dog and adapted to act when the feeding devices are separated; substantially as described.

6. In a type-writing machine, the combination of a power-driven paper-carriage having a feed-rack, a slidable column-stop bar provided with a plurality of column-stops, and having a lug, a stem attached to said feed-rack or its support and passing through said lug parallel with said slidable column-stop bar, an intermediate spring, a feed-dog, and a column-stop dog; substantially as described.

7. In a type-writing machine and in a column-stop mechanism, the combination of the column-stop rod having the series of semicircular circumferential grooves and the longitudinal groove, and the sleeve or eye having an interior radially-arranged fixed pin, to engage said circumferential grooves, and said sleeve having also a column-stop; substantially as described.

8. In a type-writing machine, the combination of a column-stop rod having a series of circumferential grooves and a longitudinal groove, the column-stop having a sleeve and an interior fixed pin adapted to be locked or engaged at any of said circumferential grooves, a column-stop dog, and a separable carriage-escapement mechanism; substantially as described.

9. In a type-writing machine, the combination of a power-driven paper-carriage having a feed-rack and a column-stop rod supported thereby and having the circumferential grooves and the longitudinal groove, the column stop or stops provided with a sleeve having an interior radial fixed pin and adapted to be locked or engaged at said circumferential grooves, the feed-dog, and the column-stop dog; both dogs being mounted to move together; substantially as described.

10. In a type-writing machine and in a column-stop mechanism, the combination with the column stops and the column-stop dog normally out of line therewith, of a detached reinforcing device to support said dog at the time of impact therewith by the column-stop during the forward jumping movement of the carriage; substantially as described.

11. In a type-writing machine and in a column-stop mechanism, the combination with the column stops and the column-stop dog, of a fixed arm or abutment attached to the framework of the machine and arranged to lie close to the side of the movable column-stop dog to support it when struck by the column-stop on the forward jump of the carriage; substantially as described.

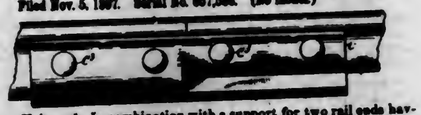
12. In a type-writing machine and in a column-stop mechanism actuated by the spacing-bar, the combination with said spacing bar, of means for limiting the depression of said spacing-bar, during spacing between words, and a key or finger-piece mounted on said bar for moving said limiting means and enabling the spacing-bar to be depressed a greater distance, for the purpose of disengaging the escapement mechanism and throwing into action the column-stop mechanism; substantially as described.

13. In a type-writing machine and in a column-stop mechanism actuated by a spacing-bar, the combination of a stop or abutment on the framework, a hinged or independently movable stop or contact-piece on the spacing-bar adapted normally to engage said stop or abutment on the framework and limit the descent of the spacing-bar, so that ordinarily the carriage may feed step by step only, and a key or finger-piece on said spacing-bar adapted to move said hinged or movable stop out of reach of the stop or abutment on the framework, and thereby permit a further depression of the spacing-bar, and the separation of the carriage-escapement mechanism and the throwing into action of the column-stop mechanism; substantially as described.

14. In a type-writing machine and in a column-stop mechanism actuated by the spacing-bar, the combination of the fixed stop or abutment, the hinged stop or contact-piece, and the spring-actuated key or finger-piece mounted on said spacing-bar; substantially as described.

15. In a type-writing machine and in a column-stop mechanism, the combination of a relatively-fixed stop or abutment, a movable stop or contact connected to the spacing-bar, and a key or finger-piece adapted when pressed upon to move the stop or contact and also by continued pressure to depress the spacing-bar; substantially as described.

16. In a type-writing machine, the combination of a power-driven paper-carriage having a feed-rack and one or more column-stops, a vibratory feed-dog, a vibratory column-stop dog connected thereto and to the dog rocker or holder, a universal bar, a spacing-key carrying a movable stop or contact, and a stop or abutment on the framework; substantially as described.



17. In a type-writing machine, the combination of a power-driven paper-carriage having a column stop or stops, a separable escapement mechanism, a column-stop dog mounted on one part of the escapement mechanism, a spacing-key, and a means mounted on said spacing-key for limiting its depression for word-spacing and movable to permit of its further depression for the purpose of throwing the column-stop mechanism into action; substantially as described.

18. In a type-writing machine, the combination of two keys connected or mounted to travel together, and a movable stop operating normally to limit the downward movement of said keys and being connected to and controlled by one of said keys; substantially as and for the purpose set forth.

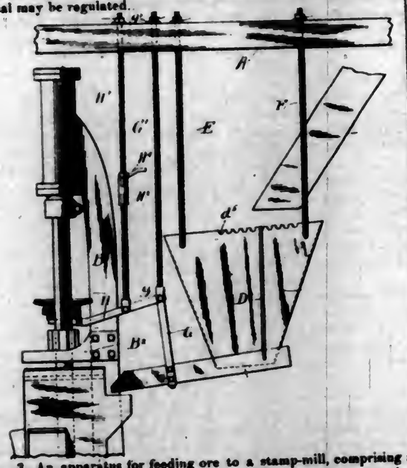
19. In a type-writing machine, the combination of a spacing-bar, a supplemental key carried thereby or attached thereto, and a stop connected to and controlled by said key; the arrangement being such that when the spacing-bar is pressed upon the stop acts to limit its depression, but when the supplemental key is pressed upon the stop is removed or thrown out of action and the spacing-bar is enabled to descend a greater distance; substantially as described.

20. In a type-writing machine, the combination of a stop-rod having a series of transverse grooves and a longitudinal groove or depression communicating therewith, and an adjustable stop provided with a sleeve and an interior radial fixed pin for holding it at or in engagement with any of said grooves; substantially as described.

605,265. RAIL-JOINT. GEORGE A. WEBB, New York, N. Y. Filed Nov. 5, 1897. Serial No. 657,886. (No model.)

Claim.—1. In combination with a support for two rail ends having two integral portions forming bearing-surfaces in different planes, of fish-plates for securing the ends of the rails together and adapted to compensate for differences in position of the remaining parts when the inner faces of the heads of said rails are in alinement, substantially as specified.

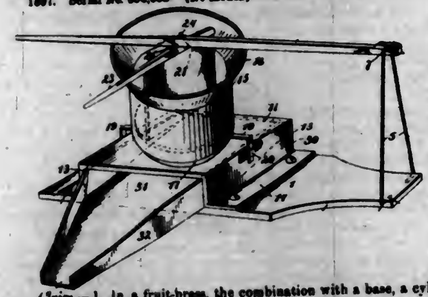
2. The combination of a rail-chair having a bolt-holding flange and a stepped bearing or rail-supporting surface upon which the ends of the rails rest, fish-plates and fastening-bolts, said fish-plates being adapted to compensate for differences in position of the rails when in position on the chair, substantially as specified.



3. The combination with a support for two rail ends having integral portions forming bearing-surfaces in different planes and with a bolt-holding flange at one edge thereof, fish-plates for securing the ends of the rails together and adapted to compensate for differences of position of the rail ends when the inner faces of the heads of said rails are in alinement, one of said fish-plates being adapted to have its edges bear against the bolt-holding flange, substantially as specified.

4. The combination of a rail-chair having a bolt-holding flange and a stepped bearing or rail-supporting surface, upon which the ends of the rails rest, fish-plates adapted to compensate for differences in position of the rails when in position on the chair, a packing or washer strip interposed between the bolt-holding flange and the adjacent fish-plate, and fastening-bolts, substantially as described.

605,266. FEEDER FOR STAMP-MILLS. GEORGE WEED, Prescott, Ariz. Filed June 13, 1897. Serial No. 640,449. (No model.)



Claim.—1. An apparatus for feeding ore to a stamp-mill, comprising a hopper open at both ends and suspended from a superstructure between an ore-bin and the stamp-mill, means for delivering ore to said hopper, a chute for delivering ore from said hopper to the stamp-mill, means for suspending said chute under the hopper comprising supporting-rods pivotally engaged at their lower ends with the rear end of said chute and engaging at their upper ends the upper edges of opposite walls of said hopper, and a flexible support engaging the forward end of said chute and movably mounted at its upper end in said superstructure, and means for oscillating said chute comprising a tappet-lever pivoted between its ends and engaging at one end said movable support, and adapted to be intermittingly engaged at its opposite end by a moving part of said stamp-mill.

2. An apparatus for feeding ore to a stamp-mill, comprising a hopper open at both ends and suspended from a superstructure between an ore-bin and the stamp-mill, means for delivering ore to said hopper, a chute for delivering ore from said hopper to the stamp-mill, means for suspending said chute under the hopper comprising supporting-rods pivotally engaged at their lower ends with the rear end of said chute and engaging at their upper ends with the upper edges of opposite walls of said hopper, and a flexible support engaging the forward end of said chute and movably mounted at its upper end in said superstructure, and means for oscillating said chute comprising a tappet-lever pivoted between its ends and engaging at one end said movable support and adapted to be intermittingly engaged at its opposite end by a moving part of said stamp-mill, said hopper being provided in its walls engaged by said supporting-rods with inclined serrated edges, by means of which the angle of the chute to the horizontal may be regulated.

3. An apparatus for feeding ore to a stamp-mill, comprising a hopper suspended from a superstructure and open at its lower end, a chute pivoted at its rear end below the open end of said hopper by means of rods which are pivotally engaged at their lower ends with said rear end of the chute, and pivoted at their upper ends to said hopper, a supporting-bail engaging the forward end of said chute, a supporting-rod movable in said structure and pivotally engaged with said bail, a lever pivoted between its ends and engaging at one end said supporting bail and rod at the junction thereof, and means on the stamp-stem for intermittingly engaging the opposite end of said lever.

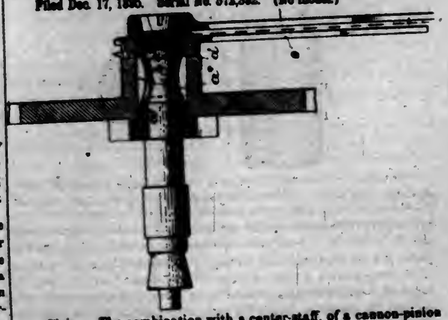
605,267. FRUIT-PRESS. ALANSON H. BALES, Glen Elder, Kans., assignor of one-half to John C. Krell, Fairbury, Nebr. Filed Oct. 22, 1897. Serial No. 655,032. (No model.)

Claim.—1. In a fruit-press, the combination with a base, a cylinder thereon having an interior strainer, and a follower working within the cylinder: of an A-shaped bail having inturned feet entering holes in and pivotally connected with the base, a lever having a notch in its upper side at one end for the reception of the angle of said bail, a swivel connection between the follower and the lever near the center of the latter, and a button on the lever adapted to be turned over said angle when the bail is in place, as and for the purpose set forth.

2. In a fruit-press, the combination with a flat base with suitable supports, a main lever pivotally connected to the base, and a follower carried by the lever; of a stand comprising a flat body with a hole therethrough, two upright ends, and two feet attached to the base, a cylinder having a contracted lower end mounted within the hole in the stand its body receiving the follower and its upper end being flaring, a hook-and-eye connection between the cylinder and stand, a supporting-bar across within the stand, and a chuté resting at its upper end on said bar and having an inclined body with raised edges and contracted delivery end passing out from the stand, as and for the purpose set forth.

3. In a fruit-press, the combination with a follower, comprising an upright body, a round flat bottom, ribs on the under side thereof, and packing seated in a groove around its edge, and means for giving it a vertically-reciprocating motion and an axially-rotating motion; of an upright cylinder comprising a truly cylindrical body, a flaring upper end, and a contracted or tapering lower end, and a strainer removably inserted within the cylinder-body and resting on said lower end thereof, as and for the purpose set forth.

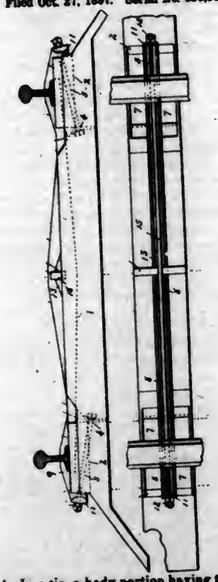
4. In a fruit-press, the combination with a stand, a cylinder carried thereby and containing a strainer, a main lever extending across the upper end of the cylinder, and connections between the stand and one end of the lever; of a follower within the cylinder, a handle rigidly attached to the upper end of the follower, and a swivel connection between the handle and lever, as and for the purpose set forth.



5. In a fruit-press, the combination with a stand comprising a flat body with an aperture therethrough, and downturned ends, and eyes on such ends; of a support for the stand, a main lever pivotally connected with the support, a follower carried by said lever, a cylinder mounted within the aperture in the stand and receiving the follower, and hooks projecting from the cylinder and adapted to enter said eyes, as and for the purpose set forth.

605,268. COMBINED SCHOOL DESK AND SEAT. JOSEPH B. BURPOOT, Mobile, Ala. Filed Jan. 24, 1898. Serial No. 667,785. (No model.)

Claim.—The legs 1 and 2 and the integral brace 3 formed with a series of arched recesses alternating with the depending lugs 4 4 and the centrally-arranged socket 5 formed with the countersunk recess 7 and internally-threaded cylindrical orifice 8, the alined plane faces of said legs, lugs and socket being provided with a series of depending spurs 6 6, in combination with the screw 10 formed with the threaded cylindrical shank 9, countersunk collar 12 and rectangular slotted head 13, substantially as shown and described.

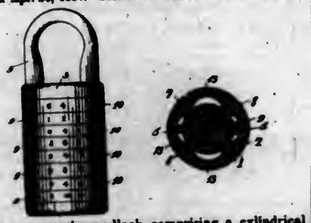


605,269. WATCH-HAND. DUANE H. CHURCH, Newton, Mass. Filed Dec. 17, 1895. Serial No. 572,382. (No model.)

Claim.—The combination with a center-staff, of a cannon-pinion having its hub extended outwardly beyond the center-staff and pro-

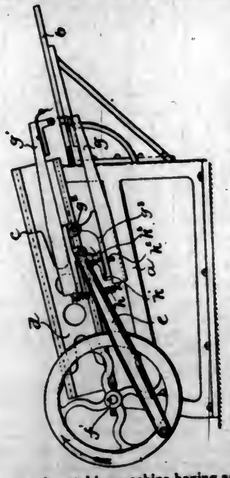
vided with an internal screw-thread, and a minute-hand having a screw formed to engage said thread.

605,270. METALLIC RAILROAD-TIE. JOHN M. CLARK, Duvall's Bluff, Ark. Filed Oct. 27, 1897. Serial No. 656,555. (No model.)



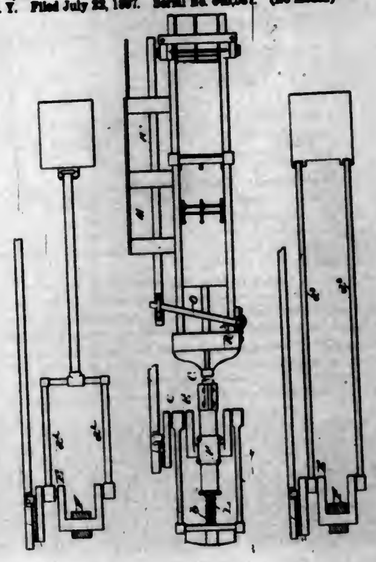
Claim.—1. In a tie, a body portion having two seats at the ends thereof, blocks resting upon said seats, rail-clamping bars situated between said blocks, and bolts secured to said body portion and to the outer ends of said rail-clamping bars.

2. In a tie, a body portion having the depressed seats at the ends thereof, the guards at the sides of said seats, the blocks resting upon said seats, the clamping-bars situated between said blocks, and the bolt secured to said body portion and to the outer ends of said clamping-bars.



3. In a tie, the clamping-bars provided with the hooks upon their upper edges to engage the base-flange of a rail, an uprising central portion having a notch situated at the center of the bar, an auxiliary fastening-bar having the upper sides of the end portions flat, an uprising central portion having an opening at the center of the bar, a key for passing through said opening, notches, and the body portion, and means for securing said clamping-bars thereon.

605,271. COMBINATION-LOCK. ISAAH H. CLEVELAND, Union, Miss. Filed Apr. 26, 1897. Serial No. 633,968. (No model.)



Claim.—A permutation-padlock comprising a cylindrical core provided with a base, a central threaded socket at its upper end, the shackle-seats, 6, of different cross-sectional area in diametrically opposite faces of the core, and the series of longitudinal V-shaped channels, 7, in the faces of the core between and parallel to the shackle-seats; the spacing-rings each having its inner edge formed of a series of arc-shaped faces, 13, struck from different centers and intersecting one with another forming a plurality of spurs, 8, spaced correspondingly to the channels, 7, in which the spurs are fitted and said arc-shaped faces producing clearance-spaces opposite to the shackle-seats; a series of tumblers alternating with the spacing-rings and having shackle-notches, 12, of corresponding cross-sectional area to the shackle-seats; a cap, 3, with a threaded stem which is screwed into the core-socket; and a shackle with its legs of different cross-sectional area fitted in the seats of the core, substantially as described.

605,272. LEATHER-STAKING MACHINE. MICHAEL H. CONNOR, Haverhill, Mass., assignor, by mesne assignments, to Elizabeth T. Connor, same place. Filed Sept. 27, 1897. Serial No. 653,100. (No model.)

Claim.—In a leather-staking machine having an inclined guideway and an inclined operating-table, the combination with the pivotally-connected working jaws and the slide rigidly secured to the upper jaw, and operating in the guideway, of a pitman-rod pivotally connected with the slide, a roll carried by said pitman-rod, a contact-plate pivotally connected to the lower jaw and having an abutment provided with a concave inclined side against which said roll bears, and means for adjusting said contact-plate to regulate the pressure of the jaws upon the work.

605,273. BALING-PRESS. PETER K. DODGSON, Louisville, N. Y. Filed July 22, 1897. Serial No. 645,587. (No model.)

Claim.—1. In a baling-press the combination with the press-case traverser working therein, pitman for operating said traverser and cross-head connected with said pitman, of a double crank journaled in fixed bearings, links connecting said crank and cross-head and a power lever or sweep mounted on and entirely supported by one of the crank-pins of the crank; substantially as described.

2. In a baling-press the combination with the press-case, traverser and pitman mounted in bearings to slide longitudinally, of a crank journaled in fixed bearings, a link connecting the crank-pin and pitman and a horse-lever or sweep mounted on and entirely supported by said crank-pin on the end opposite the bearing in which the crank is journaled; substantially as described.

3. In a baling-press, the combination with the press-case, traverser and pitman journaled to slide longitudinally, of a crank journaled in fixed bearings, a link connecting the crank-pins and pitman, an independently-movable horse-lever mounted on and entirely supported by said crank-pin and a clutch interposed between said horse-lever and crank-pin; substantially as described.

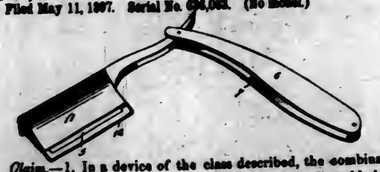
4. In a baling-press the combination with the press-case, traverser, pitman mounted to slide longitudinally, crank journaled in fixed bearings and a link connecting the crank-pin and pitman, of a bearing carried by said crank-pin and suspended in line with the center on which said crank rotates, a horse-lever or sweep mounted on said bearing with means for connecting the horse-lever or sweep and crank-pin for simultaneous rotation; substantially as described.

5. In a baling-press the combination with the press-case, traverser, pitman mounted to slide longitudinally, crank journaled in a fixed bearing and link connecting the crank-pin and pitman, of a suspended support mounted on the crank-pin and extending back in line with the center of rotation of the crank and a horse-lever or sweep mounted on said support; substantially as described.

6. In a baling-press, the combination with the press-case, traverser, pitman mounted to slide longitudinally, crank journaled in a fixed bearing and link connecting the crank-pin and pitman, of a suspended support mounted on the end of the crank-pin opposite the bearing in which the crank is journaled and extending back in line with the center of rotation of the crank, and a horse-lever or sweep, journaled on said support with means for connecting the support and lever; substantially as described.

7. In a baling-press, the combination with the press-case, traverser, pitman mounted to slide longitudinally, crank journaled in a fixed bearing and link connecting the crank-pin and pitman, of a suspended support mounted on the end of the crank-pin opposite the bearing in which the crank is journaled and extending back in line with the center of rotation of the crank, a horse-lever or sweep journaled on said support and a clutch interposed between said support and horse-lever to permit the crank to rotate at a higher rate of speed than the horse-lever; substantially as described.

8. In a baling-press, the combination with the press-case, pipe connection rigidly connected therewith, traverser and pitman extending through the pipe connection, of a double crank journaled on the pipe connection, links connecting the crank-pins and pitman, a suspended support mounted on one of the crank-pins opposite the journal for the crank, a horse-lever journaled on said support, and in line with the axis of the crank, and a clutch interposed between the horse-lever and support; substantially as described.



9. In a baling-press, the combination with the press-case, traverser and power mechanism for advancing the traverser, of a reciprocating condenser, a spring for returning said condenser to its retracted or open position, a lever journaled on the press-case and adapted to be moved by the traverser when retracted, and a connection between said lever and condenser for advancing the condenser against the tension of its retracting-spring; substantially as described.

10. In a baling-press, the combination with the press-case, traverser, and power mechanism for advancing the traverser, of a reciprocating condenser, a spring for moving said condenser to its retracted or open position, and side slides connected with said condenser, of levers journaled at the lower end at the bottom of the press-case, and connected at their upper ends with said side slides, and coöperating contacting surfaces on the bottoms of the levers and traverser respectively, adapted to contact when the traverser is at the extreme retracted position, whereby when the traverser is in this position the condenser is advanced to condense a preliminary charge of matter.

11. In a full-circle press, or press in which the horse moves constantly in one direction, the combination with the press-case, traverser, pipe connection and pitman working through said pipe connection, of a crank journaled on the pipe connection and connected with the pitman by a link, of a horse-lever journaled on an axis coincident with the axis of the crank and a clutch connection between the horse-lever and the crank; substantially as described.

12. In a baling-press power, the combination of the double crank-shaft journaled to a rigid extension from the press-frame, with connections to reciprocate the traverser, and provided with a horse-lever pivoted on a suspended center extending from and supported by the upper crank-wrist, and an automatic connection between said horse-lever and extension from the crank-wrist, whereby the crank is free to move forward faster than the horse-lever, substantially as and for the purpose set forth.

605,274. SAFETY-RAZOR. ELIJAH E. DEPUTY, Milford, Del. Filed May 11, 1897. Serial No. 636,063. (No model.)

Claim.—1. In a device of the class described, the combination of a blade-receiving frame provided with arms, an adjustable blade arranged within the frame and provided with a threaded socket, and a centrally-arranged adjusting-screw mounted on the frame and engaging the threaded socket, and forming a pivot for the blade, whereby the latter is adapted to be turned transversely of the frame, substantially as described.

2. In a device of the class described, the combination of a frame, an adjustable blade arranged therein and provided with a threaded socket, a spring interposed between the blade and the frame, and a screw mounted on the frame and engaging the threaded socket to adjust the blade, said screw retaining the spring in place and serving as a pivot for the blade, whereby the latter is adapted to be partially rotated, substantially as described.

3. In a device of the class described, the combination of a frame, a blade pivotally mounted in the frame and arranged to swing outward therefrom to expose the inner edges of the blade and the frame, whereby the parts may be thoroughly wiped and dried after use, and a removable casing covering the blade and the frame and locking the former in its operative position, substantially as described.

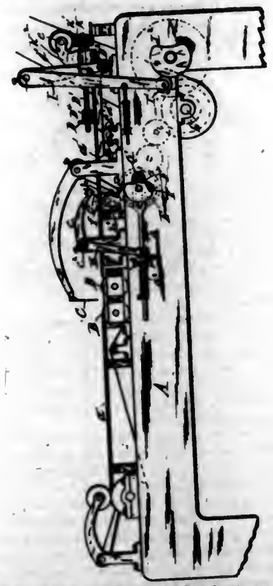
4. In a device of the class described, the combination of a frame having arms provided with tapering recesses, a blade mounted in the frame, and a guard extending in advance of the blade and pivoted in the said recesses, whereby it is permitted to swing laterally of the blade, substantially as and for the purpose described.

5. In a device of the class described, the combination of a frame provided at its ends with recesses, a blade arranged in the frame, and a substantially rectangular guard having its ends arranged in the said recesses and provided at their terminals with pivots to permit the guard to swing in the recesses, said guard being adapted to be sprung into and out of engagement with the recesses, substantially as described.

6. In a device of the class described, the combination of a substantially rectangular frame provided with a shank, an adjustable blade mounted in the frame, and a removable casing conforming to the configuration of the frame and provided at opposite sides with longitudinal ribs, substantially as described.

7. In a device of the class described, the combination of a frame having a shank, an adjustable blade mounted in the frame, a casing removably mounted on the frame and conforming to the configuration thereof, a detachable guard interlocked with the frame, and a handle pivoted to the shank and provided at the inner faces of its sides with recesses, substantially as and for the purpose described.

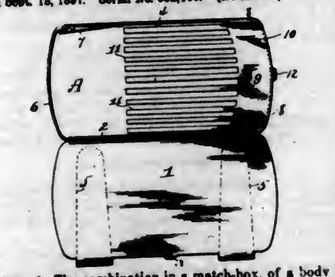
605,275. PAPER-REGISTERING MACHINE. TALBOT C. DEXTER, Pearl River, and JAMES J. PARKER, Brooklyn, N. Y., assignors to the Dexter Folder Company, New York, N. Y. Filed Aug. 6, 1897. Serial No. 647,316. (No model.)



Claim.—1. A paper-registering instrument consisting of a rotary roller disposed to receive upon the top of its periphery the slitted portion of the sheet in transit, and a pin or point carried over said roller and to and from the same to enter into the slit made in the paper for that purpose.

2. A paper registering instrument comprising a soft-rubber-faced roller disposed to receive upon the top of its periphery the slitted portion of the paper, a registering-pin over said roller and moving intermittently to said roller to press the paper upon it and enter into the slit in the paper, and mechanism imparting motion to said roller and pin.

3. A paper-registering instrument comprising a soft-rubber-faced roller disposed to receive the slitted portion of the paper upon the top of its periphery, a bridge rising from the plane of the travel of the paper adjacent to the aforesaid roller, a registering-pin moving intermittently to the roller to press the paper upon it and in conjunction with the bridge open the slit in the paper preparatory to the entering of the pin into the slit, and mechanism imparting motion to the said roller and pin, as set forth.

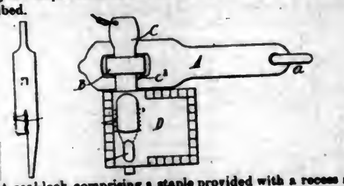


4. A paper-registering instrument consisting of a rotary roller

provided with a friction-surface on its periphery and receiving upon it the slitted portion of the sheet, a rock-arm over said roller moving intermittently toward and from the roller and a pin attached to the free end of said rock-arm and entering into the slit in the sheet, as set forth.

5. In combination with the sheet-delivering tapes, sheet-supporting bars and alternately advancing and receding end-gage, a rotary shaft extending across the machine, rubber-faced rollers secured to said shaft and receiving upon their peripheries the slitted portions of the sheet, rock-arms over said rollers moving intermittently to and from the rollers, and pins attached to the free ends of said arms and entering into the slits in the sheet, as set forth.

605,276. MATCH-BOX. RANDALL M. DIXON, Philadelphia, Pa. Filed Sept. 18, 1897. Serial No. 652,169. (No model.)



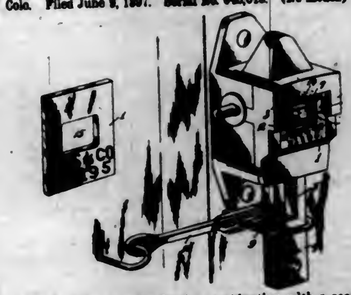
Claim.—1. The combination in a match-box, of a body portion having a lid at one end, guides in said body portion and a comb removably placed in said guides and having spring-fingers to bear against the matches in said body portion, substantially as set forth.

2. The combination in a match-box, of a body portion having a lid at one end, guides in the other end of said body portion, a comb having spring-fingers to bear on matches in the body portion and adapted to slide freely in said guides, and a finger-piece on said comb whereby to remove it from the body portion when the box is to be filled with matches, substantially as set forth.

3. As an article of manufacture, a match-box comprising a main body portion or receptacle having a hinged side and end, and a removable comb.

605,277. SEAL-LOCK. PRESTON C. DOCKSTADER, Colorado Springs, Colo. Filed Aug. 26, 1897. Serial No. 649,556. (No model.)

Claim.—1. A seal-lock comprising a staple, a pin having a toothed slot, a seal adapted to engage said slot, and a shoulder on the pin for engaging the staple in the manner and for the purpose substantially as described.



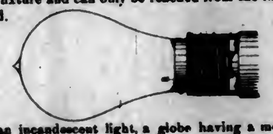
2. A seal-lock comprising a staple provided with a recess at one side of its opening, a pin having a projection and having a toothed slot, and a seal having webs for engaging the slot-teeth, substantially as described.

3. A seal-lock comprising a staple, a pin adapted to enter the staple-opening and provided with a toothed slot and a reduced lower end below said slot, and a seal provided with webs for engaging the slot-teeth and with perforations for engaging said lower end, in the manner and for the purpose substantially as described.

4. A seal-lock comprising a staple provided with arms extending downwardly therefrom, a seal having openings for said arms, and webs intermediate of said openings, and a pin having a toothed slot adapted to engage the webbed portion of the seal and having a reduced lower end for engaging perforations in the seal, substantially as described.

5. In a seal-lock, the combination of a staple, a pin having a toothed slot, a seal adapted to engage said slot, a shoulder on the pin for engaging the staple, and a stop-piece pivotally secured in the path of the pin and adapted to be moved to engage the same, substantially as set forth.

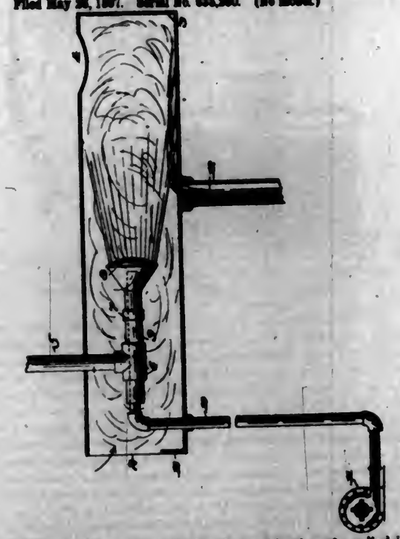
605,278. SEAL-LOCK. WILLIAM K. EDGAR, Colorado Springs, Colo. Filed June 9, 1897. Serial No. 640,013. (No model.)



Claim.—1. In a seal-lock, the combination with a seal-seat and a movable member arranged in rear thereof, for advancement in a direction intersecting the plane of the same, of a seal having an opening to receive, and expose for inspection, the front end of said movable member, the opening in the seal being of greater area than the cross-section of the engaging portion of the movable member, to fit loosely on the latter and prevent the temporary fitting of a false plug, of the same cross-sectional area as the movable member, in said opening, substantially as specified.

2. A frangible seal having an opening extending entirely therethrough, in combination with a lock-casing having a seat into which the seal may be slid, a locking-pin mounted in rear for advancement in a direction intersecting the plane of the seal, and adapted to engage and fit loosely at its front end in the opening of the seal to prevent the unseating thereof, and locking devices for the locking-pin, including actuating means arranged in rear of and held inoperative by the seal, and visible through said opening in the seal between the sides of the opening and the engaging pin, substantially as specified.

3. As a new article of manufacture, a frangible seal having an opening for engagement by the movable member of a lock, which opening is of greater area than the cross-section of the engaging portion of said member, to allow view through the opening, between its walls and the sides of the engaging member, and prevent fitting the opening with a false plug of the same, or approximately the same, cross-sectional area as said movable member, substantially as specified.

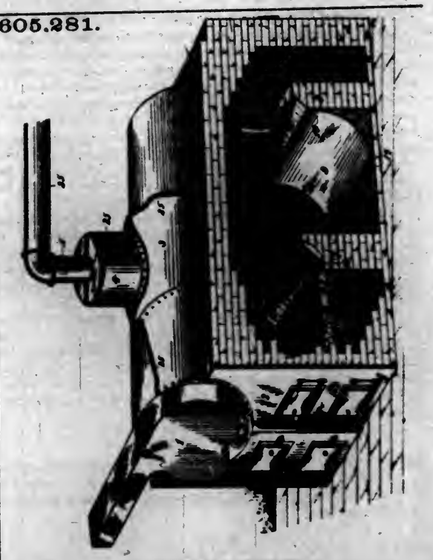


605,279. SAFETY-LOCK FOR INCANDESCENT LAMPS. ERNST FALLER and HERRMANN HERRSTATT, San Francisco, Cal. Filed Sept. 17, 1897. Serial No. 651,968. (No model.)

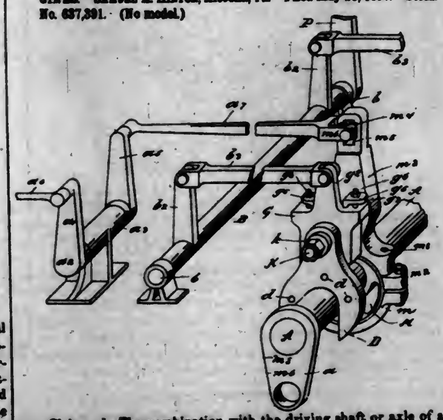
Claim.—1. An incandescent-light globe having a metallic end adapted to engage with the corresponding portion of the permanent fixture, a catch formed in one of the engaging parts and a corresponding automatically-engaging tongue upon the other, said tongue projecting inwardly whereby it is concealed within the exterior portion of the fixture and can only be reached from the interior of said metallic end.

2. In an incandescent light, a globe having a metallic screw-threaded end or base, the permanent fixture having the corresponding screw-threaded portion into which the globe portion is adapted to interlock, a shoulder or catch formed upon the entering interlocking portion, and an elastic automatically-engaging tongue projecting inwardly from the other portion of the fixture so that it can only be reached from the interior of said end or base whereby the two are engaged and permanently locked when the globe is in position for operation.

605,280. SMOKE-CONDENSER. JOHN C. GREEN, Cleveland, Ohio. Filed May 26, 1897. Serial No. 638,260. (No model.)



Claim.—In a smoke-condenser, the combination of a cylindrical condensing-chamber having its axis in a horizontal plane and provided with inlet and outlet openings at opposite extremities, a water-pipe extending into said chamber near its inlet, an air pipe projecting into said chamber near its inlet and extending into and encircled by said water-pipe and having an open annular air-space intermediate of air-pipe and water-pipe, said water-pipe provided on its extremity with a spray-nozzle discharging into said chamber, and an escape-pipe opening from the bottom of said condensing-chamber immediately of said inlet and outlet openings, substantially as set forth.



605,281. BOILER-FURNACE. JOHN W. KARBER and WILLIAM J. GALLOWAY, Pekin, Ill. Filed July 22, 1897. Serial No. 645,532. (No model.)

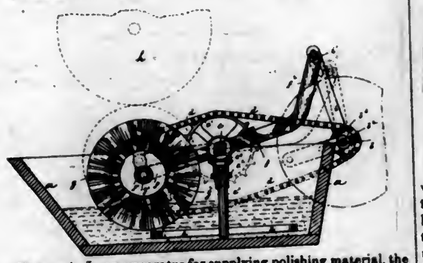
Claim.—The combination with a boiler-setting, a grate, and a boiler, of a front bridge-wall supporting the grate and terminating below the boiler to provide a passage of sufficient area for the free escape of the products of combustion from the grate-chamber, a rear wall arranged within the setting parallel to the bridge-wall to form the combustion-chamber, said rear wall terminating on a plane above the front bridge-wall and close to the boiler, and forming with the latter a contracted throat or passage of an area greater than the cross-sectional area of the boiler-tubes, and a curved deflector within the combustion-chamber and terminating below the upper edges of the front and rear walls, whereby the rear wall intercepts the products of combustion as the flow from the combustion-chamber and the restricted throat or passage avoids undue checking of the draft, substantially as described.

605,281.

605,282. STEAM-VALVE FOR LOCOMOTIVES OR OTHER ENGINES. SAMUEL A. HIPPEN, Altoona, Pa. Filed May 20, 1897. Serial No. 637,391. (No model.)

Claim.—1. The combination with the driving shaft or axle of a locomotive or engine, of brackets or supports mounted thereover, a roller box or frame pivotally connected thereto, an eccentric mounted on said shaft or axle adjacent to said roller box or frame, a strap or band encompassing the same, an upwardly-directed extension, an antifriction-roller supported thereby and operating in said roller box or frame, connections between said upwardly-directed extension and the steam-chest, means for operating said roller box or frame and means for taking up the wear on the bearing-surfaces of said roller box or frame, substantially as described.

2. The combination with the driving shaft or axle of a locomotive or engine, of brackets or supports mounted thereover, a roller box or frame pivotally connected thereto, an eccentric mounted on said shaft or axle adjacent to said roller box or frame, a strap or band encompassing the same, an upwardly-directed extension, an antifriction-roller supported thereby and operating in said roller box or frame, connections between said upwardly-directed extension and the steam-chest, means for operating said roller box or frame, adjustable wedges for taking up the wear on the bearing-surfaces of said roller box or frame, and means for securing said wedges in position, substantially as described.



3. The herein-described valve-operating mechanism for locomotives or engines, comprising the main drive shaft or axle of the loco-

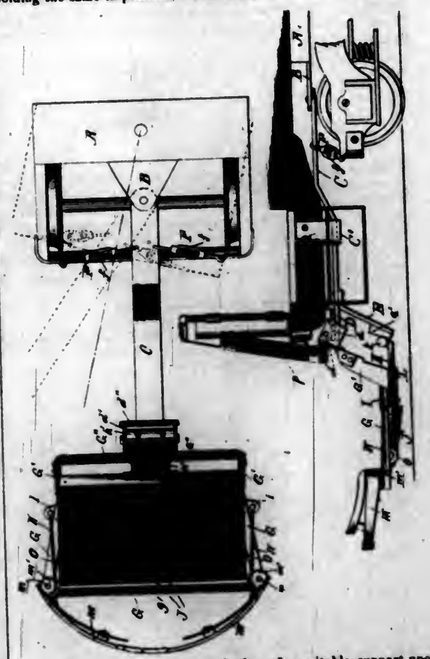
motive or engine, brackets or supports mounted thereover, roller boxes or frames pivotally connected with said brackets or supports, eccentrics mounted on said shaft or axle adjacent to said roller boxes or frames, and provided with straps or bands having outwardly-directed extensions, rollers connected with said upwardly-directed extensions, and operating in said roller boxes or frames, operative devices connecting said extensions of the eccentric straps or bands with the valves, and means for operating said roller boxes or frames, consisting of a shaft, suitably supported and provided with crank-rods which are connected with said roller-boxes said shaft being also provided with means for operating the same, substantially as shown and described.

4. In a valve-gear for locomotive or other engines a roller box or frame comprising a plate, guide-flanges supported thereon, a well for oil or other lubricant attached to the lower portion thereof, a roller operating in said frame and connections between said roller and the power-shaft, and between said roller and the steam-chest, substantially as described.

5. In a valve-gear for locomotive or other engines a roller box or frame comprising a plate, guide-flanges supported thereon, wedge-shaped bars bearing against said flanges and removably attached thereto, a well for oil or other lubricant attached to the lower portion thereof, a roller operating in said frame, and connections between said roller and the power-shaft, and between said roller and the steam-chest, substantially as described.

605,283. SUPPLYING POLISHING COMPOUNDS TO POLISHING OR CUTTING TOOLS. FRANK HOLLAND, Brooklyn, N. Y., assignor to James Cavanagh, same place. Filed Aug. 24, 1897. Serial No. 649,309. (No model.)

Claim.—1. In an apparatus for supplying polishing material, the combination of a box with a pivoted frame having a bearing, a revoluble brush hung within said bearing, means for oscillating the frame, and means for revolving the brush during the oscillation of the frame, substantially as specified.



2. An apparatus for supplying polishing material composed of a box, a power-shaft having sprocket-wheel b^3, a shaft c, having sprocket-wheel c', a mixing-blade e, having shaft e', intergeared with shaft c, an oscillating frame f, a brush having shaft g', hung in said frame, a sprocket-wheel g^3, on shaft g', a chain engaging wheels b^3, c', g^3, and a crank connection between shaft b, and frame f, for imparting an oscillating motion to said frame, substantially as specified.

605,284. CAR-FENDER. GEORGE C. HUTCHESON, St. Louis, Mo., assignor, by mesne assignments, of one-half to J. Reed Elliott, same place. Filed Oct. 7, 1897. Serial No. 654,433. (No model.)

Claim.—1. The combination with a car-body and its truck, of a support connected to said car-body and truck so as to swing laterally when the car is going around a curve, a fender pivotally mounted on the front end of said support and movable therewith, mechanism for holding said fender in an elevated position, and a trip arranged in advance of the fender for releasing the same and permitting it to drop when the trip strikes an object, substantially as described.

2. The combination with a fender, of a suitable support to which the same is pivoted, means on the fender for engaging said support at its lower end for holding the fender in an elevated position, a lever operatively connected with said elevating mechanism, a swinging arm projecting out in front of the fender in its normal position, and a connection between said swinging arm and said lever; substantially as described.

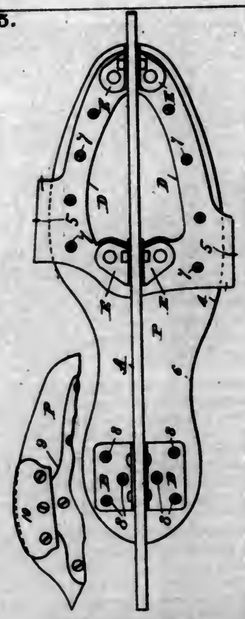
3. The combination with a fender of a suitable support to which the same is pivoted, means on the fender for engaging said support at its lower end, for holding the fender in an elevated position, a lever operatively connected with said elevating mechanism, a swinging arm projecting out in front of the fender in its normal position, a connection between said arm and said lever, and another swinging arm cooperating with the free end of said first-mentioned swinging arm for holding the same in position; substantially as described.

4. The combination with a fender, of a suitable support upon which said fender is pivotally mounted, a movable piece arranged on the bottom of the fender and engaging the lower end of said support, levers for holding said movable piece against the support to elevate the fender, spring for retracting said levers, two arms pivotally mounted on the front outer edge of the fender, one of said arms having spring-jaws on its end for engaging the end of the other arm, and connections between said arms and levers; substantially as described.

5. The combination with the fender-support comprising the brackets D and E, the former of which consists of pivot projections d'', a laterally-extending plate d and curved studs d'' on said plate, the latter comprising lateral wings having flanged edges d', of a fender carrying a bracket H', which bracket is provided with side bearing edges h' and a bar h'', said parts cooperating with the bracket D and its associate parts, and a sliding piece K having the bearing-pieces k for cooperating with the wings d' on the bracket E, and a lever or levers for engaging the said piece K, substantially as described.

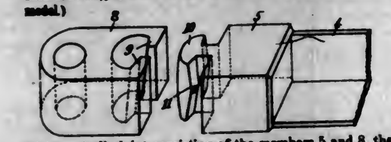
6. The combination with the car-body, of a pivoted truck arranged thereunder, a feeder-carrying tongue pivoted on the car-body in advance of the pivotal point of the truck, and a connection between said pivoted truck and said fender-carrying tongue, substantially as described.

7. The combination with a car-body, of a tongue C pivoted thereon, a fender-basket carried at the front end of the tongue, a truck pivotally mounted on the car-body back of the pivotal point of the tongue C, and a connection or connections between said pivotal tongue and the forward end of the truck, said connection including turnbuckles, substantially as described.



605,285. HOCKEY-GAME SKATE. EVERETT H. BARNEY, Springfield, Mass. Filed Dec. 3, 1897. Serial No. 660,607. (No model.)

Claim.—1. In a skate of the class described, a sole-plate therefor having on one edge thereof a laterally-projecting substitute runner-section, substantially as and for the purpose set forth.



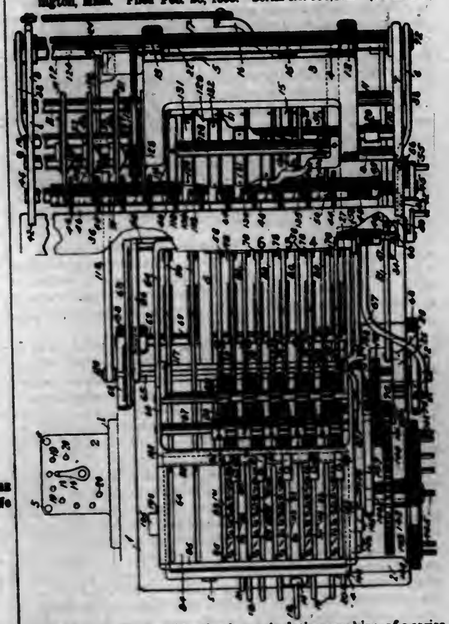
2. In a skate of the class described, a sole-plate therefor having on its opposite edges laterally-projecting substitute runner-sections, integral therewith, substantially as set forth.

3. In a skate of the class described, a sole-plate therefor combined with one or more exchangeable substitute runner-sections, and means for securing said section or sections at the outer border of said sole-plate, substantially as set forth.

605,285.

605,286. REVERSIBLE RAIL-GRIP FOR BEDSTEADS. GEORGE BRAHN, Brooklyn, N. Y. Filed Oct. 26, 1897. Serial No. 656,475. (No model.)

Claim.—A slip-joint consisting of the members 5 and 8, the former provided with a head 10, having central bearing-surfaces from which the head tapers toward each end and a face abutting against the second member, and the second member having wedge-shaped portions entering between said bearing-surfaces and said abutting face, and engaging said head at the central bearing-surfaces only substantially as and for the purpose set forth.



605,287. CAR-COUPLING. JAMES H. CUNNINGHAM, Worcester, Mass. Filed Nov. 24, 1897. Serial No. 659,667. (No model.)

Claim.—1. In a coupling device for cars, the combination of a draw-head 10 having a socket for a coupling-link, a guide 12 for a coupling-pin extending up from the upper surface of the draw-head 10, a perforated slide 14 on the upper surface of the draw-head 10, and an operating-lever 16 pivoted in the draw-head above the coupling-link socket, and having a tailpiece 17 normally tending to retract the slide 14, and located in position to be engaged by a coupling-link to move the slide in the opposite direction from that traversed by the coupling-link so as to release the coupling-pin, substantially as described.

2. In a coupling device for cars, the combination of a draw-head 10 having a flaring mouth 11 and a socket for a coupling-link, a guide 12 extending up from the upper surface of the draw-head 10 for supporting and directing a coupling-pin, a perforated slide 14 mounted on the upper surface of the draw-head 10, a lever 16 pivotally mounted in the draw-head 10, and having a tailpiece 17 normally extending down below the pivot of the lever 16 in position to be engaged by the coupling-link to force the slide forward in the opposite direction from that traversed by the coupling-link, a lifting-link 18 for raising the coupling-pin from the top of the car, a rock-shaft 20 for lifting the coupling-pin from the side of the car, and means for locking said connections to support the coupling-pin in its raised position, substantially as described.

605,288. CALCULATING-MACHINE. GEORGE B. GRANT, Lexington, Mass. Filed Feb. 20, 1896. Serial No. 580,162. (No model.)

Claim.—1. The combination in a calculating-machine, of a series of toothed numeral-wheels, a series of corresponding toothed adding gears independently adjustable relatively to their corresponding numeral-wheels, and mechanism to move the series of adding-gears in unison throughout a fixed distance, whereby each numeral-wheel will be operated by its adding-gear an amount determined by the adjustment of the latter, substantially as described.

2. The combination in a calculating-machine, of a series of toothed numeral-wheels, a series of corresponding toothed adding-gears independently adjustable relatively to their corresponding numeral-wheels, a locking device to lock said adding-gears in adjusted position, and mechanism to move the series of adding-gears in unison throughout a fixed distance, the locking device retaining said gears in fixed position relatively to each other during such movement, substantially as described.

3. The combination in a calculating-machine of a series of toothed numeral-wheels, a corresponding series of adjustable toothed adding-gears, mechanism to move the series of adding-gears as a whole through a limited fixed distance with respect to the series of numeral-wheels from an original position, and mechanism to disengage the gears and the numeral-wheels at a definite point of the movement and to maintain them disengaged during the return of the gears to their original position, substantially as described.

4. The combination in a calculating-machine, of a series of toothed numeral-wheels, a series of corresponding toothed adding-gears independently adjustable relative to their corresponding numeral-wheels, means to reciprocate the series of adding-gears in unison through a fixed distance, whereby each numeral-wheel will be operated in accordance with the adjusted position of its corresponding gear, mechanism to disengage the wheels and gears at a definite point in the movement, and to maintain them disengaged during the return of the gears to original position, and connections between the disengaging mechanism and the means for reciprocating the series of gears to automatically operate said mechanism, substantially as described.

5. The combination in a calculating-machine of a series of

toothed numeral-wheels, a corresponding series of adjustable toothed adding-gears, and mechanism to give the series of adding-gears a reciprocating motion as a whole through a limited fixed distance with respect to the series of numeral-wheels, whereby each adding-gear acts upon the corresponding numeral-wheels and returns to its original position, substantially as described.

6. The combination in a calculating-machine, of a series of adding-gears, a series of numeral-wheels to be engaged and driven by the adding-gears, actuating mechanism to move the series of adding-gears in unison throughout the whole of a fixed distance with respect to the numeral-wheels, and disengaging means controlled by said actuating mechanism to disengage the wheels and gears when the latter have reached and are stationary at the end of their operative stroke, substantially as described.

7. The combination in a calculating-machine, of a series of numeral-wheels, a series of independently-adjustable adding-gears, means to lock them in adjusted position, and a crank and connecting mechanism to give the series of locked adding-gears a reciprocating motion in unison throughout a fixed distance with respect to the series of numeral-wheels, and mechanism to disengage the wheels and gears at the end of the reciprocation, whereby the adding-gears act upon the numeral-wheels, are disengaged therefrom while stationary, and finally are returned to their original position, substantially as described.

8. The combination in a calculating-machine, of a series of numeral-wheels, a series of independently-adjustable straight-adding rack gears, means to lock said gears in adjusted position, and mechanism to give one of the series a reciprocating motion in unison throughout a fixed distance with respect to the other series, substantially as described.

9. The combination in a calculating-machine, of a series of toothed numeral wheels, a series of corresponding toothed adding-gears independently adjustable relatively to their numeral-wheels, means to lock said gears in adjusted position, and mechanism to move one of said series through a fixed distance relatively to and to cooperate with the other series, whereby each of the numeral-wheels will be operated by and to an extent depending upon the adjustment of its corresponding adding-gear, substantially as described.

10. The combination in a calculating-machine of a series of numeral-wheels, a sliding and oscillating numeral-carriage, an adding-carriage, a crank, and a cam and connecting mechanism, whereby the adding-carriage is given a reciprocating motion, and the numeral-carriage an oscillating motion, substantially as described.

11. The combination in a calculating-machine of a series of numeral wheels, two series of adding devices, each member of one series being geared to the corresponding member of the other series, in pairs, and being adjustable in position with respect to the numeral-wheels, whereby the adjustable member when being adjusted moves the other member in the contrary direction, substantially as described.

12. The combination in a calculating-machine of a series of numeral-wheels, two series of adding devices and connecting mechanism between the two series, whereby when one series is adjusted to represent any number the other is automatically adjusted to represent the arithmetical complement of that number, substantially as described.

13. The combination in a calculating-machine of a series of numeral-wheels, a series of positive adding-gears and a series of negative adding-gears, and a train of gears connecting each positive adding-gear with a corresponding negative adding-gear, whereby when either positive adding-gear is adjusted the corresponding negative adding-gear is adjusted a like distance in the opposite direction with respect to the numeral-wheels, substantially as described.

14. The combination in a calculating-machine of the adding-carriage carrying a double series of positive and negative adding devices, the series of numeral-wheels and mechanism to shift the adding-carriage with respect to the numeral-carriage to bring either series of adding devices into working position, substantially as described.

15. The combination in a calculating-machine of a positive rack and a negative rack each provided with teeth on its edge, a gear meshing with the positive rack, and a gear meshing with that gear and in engagement with the teeth of the negative rack, whereby the two racks are simultaneously moved in opposite directions, substantially as described.

16. The combination in a calculating-machine of the indicator-wheels 58 on the laterally-adjustable indicator-bar 36, the fixed post 40 holding the indicator-bar, the oscillating numeral-carriage 6 and means for laterally adjusting it, and the arms 38 attached to the numeral-carriage and to the indicator-bar, substantially as described.

17. The combination in a calculating-machine of the reciprocating adding-carriage 64, the link 119, the lever 122, the gear 126 attached to the lever 122, the carry-shaft 128 and the gear 127 on the carry-shaft and running in the gear 126, whereby the carry-shaft is oscillated in unison with the reciprocation of the adding-carriage, substantially as described.

18. The combination in a calculating-machine of the cam-wheel 25, the frame 3 the lever 21, pivoted upon the frame 3, the laterally-adjustable numeral-carriage 6, the guide-rod 10 upon the numeral-carriage and the link 29 sliding upon the guide-rod and attached to the lever, substantially as described.

19. The combination in a calculating-machine of the frame 3, the lever 21 pivoted upon the frame 3, mechanism to oscillate the lever the numeral-carriage 6, and means for laterally adjusting it with respect to the lever, substantially as described.

20. The combination in a calculating-machine of the driving-shaft 26, the ratchet-wheel 25 having a single tooth 74 and one or more holding-teeth at a distance from the tooth 74, and the detent 73, whereby reverse motion of the driving-shaft is permitted only near the single tooth, substantially as described.

21. The combination in a calculating-machine, of a toothed adding-gear, and a setting-pin attached thereto and adjustable in a setting-slot, the opposite walls of the slot being notched in a predetermined manner at points between the ends of the slot, the notches to be entered by the setting-pin, substantially as described.

22. The combination in a calculating-machine of the setting-pin 82, the setting-slot 83, the pin 92, and the shoulder 93, substantially as described.

23. The combination in a calculating-machine, of a series of numeral-wheels, a sliding and oscillating numeral-carriage, an adding-carriage, and means to reciprocate the adding-carriage and to oscillate the numeral-carriage, substantially as described.

24. The combination in a calculating-machine of the adding-gear 78, the setting-pin 82, setting-plate 84 having a slot 83, and setting index-wheel 86 geared to the adding-gear, whereby the position of the pin in the slot is shown upon the index-wheel, substantially as described.

25. The combination in a calculating-machine of an adding-carriage, a series of toothed adding-gears carried by the carriage and separately adjustable in position upon it, a correcting-bar and mechanism forcing it into the teeth of the adding-gears, whereby the correcting-bar corrects any error of less than half a tooth in the position of the adding-gears, substantially as described.

26. The combination in a calculating-machine of an adding-carriage means for reciprocating the adding-carriage, a toothed adding-gear carried by the adding-carriage, a device locking the adding-gear to the adding-carriage and releasable by the momentum of the adding-gear, and a checking-weight operating upon the locking device and opposing its momentum to that of the adding-gear, whereby the effort of the adding-gear to move itself in the adding-carriage by its own momentum is overcome by the momentum of the locking device, substantially as described.

27. The combination in a calculating-machine of the toothed adding-gear 78, the locking-bar 102, and the momentum-check 105, substantially as described.

28. The combination in a calculating-machine of an adding-carriage, a series of toothed adding gears carried by the adding-carriage and separately adjustable in position upon it, mechanism to move the adding-carriage from a fixed position and return it to that position again, and devices locking all the toothed adding-gears in their adjusted positions when the adding-carriage moves from the said fixed position and releasing them when it returns to that position again, substantially as described.

29. The combination in a calculating-machine of an adding-carriage, a series of toothed gears carried by the carriage and separately adjustable in position upon it, mechanism to move the adding-carriage from a fixed position and to return it to that position again, a locking-bar engaging in the teeth of all the adding-gears, and devices engaging the locking-bar and adding-gears when the carriage moves from the said fixed position and releasing them when it returns to that position, substantially as described.

30. The combination in a calculating-machine of the reciprocating adding-carriage 64, the toothed adding-gears 78, the locking V-bar 102, the swinging locking-lever 102', and the locking-guide 107, substantially as described.

31. The combination in a calculating-machine of the reciprocating adding-carriage 64, the toothed adding-gears 78, the locking V-bar 102, the swinging locking-lever 102', the locking-guide 107, and the releasing-weight 104, substantially as described.

32. The combination in a calculating-machine of the shifting handle 14, the numeral carriage 6, mechanism connecting the shifting handle with the numeral carriage, and the indicating-pins 19 placed close to the path of motion of the shifting handle 14, whereby the position of the numeral-carriage is indicated by the position of the shifting handle with respect to the pins, substantially as described.

33. The combination in a calculating-machine of the shifting handle 14 at the front of the machine, the lever 16 at the back of the machine, the rock-shaft 15 connecting the shifting handle and the lever, the numeral-carriage 6, and the link 17 connecting the lever and the numeral-carriage, substantially as described.

34. The combination in a calculating-machine of an operating-shaft one rotation of which causes the machine to perform one operation of addition, a speed-wheel having several equidistant driving-handles, a train of gears connecting the speed-wheel and operating-shaft and having a velocity ratio equal to the number of said driving-handles, whereby the rotation of the speed-wheel by moving any one of the several driving-handles from its position to a fixed position causes the machine to perform a definite number of operations of addition, substantially as described.

35. The combination in a calculating-machine of an operating-shaft one rotation of which causes the machine to perform one operation of addition, a speed-wheel having nine driving-handles, a train of gears connecting the speed-wheel and the operating-shaft and having a velocity ratio of nine to one, whereby the rotation of the speed-wheel by moving any handle from its position to a fixed position causes the machine to perform from one to nine operations of addition according to the handle moved, substantially as described.

36. The combination in a calculating-machine of a speed-wheel having several handles, and a fixed and figured dial indicating the position of the handles, substantially as described.

37. The combination in a calculating-machine of a series of numeral-wheels, each numeral-wheel having a carrying-pin upon it, a series of carrying-levers, a wing upon the side of each carrying-lever, a series of helically-arranged carrying-teeth, a series of carrying-lever returners, and a series of carrying-tooth returners, whereby when a carrying-lever has been moved by a carrying-pin a carrying-tooth will be thrown between the teeth of the next numeral-wheel for the purpose of carrying the tens, substantially as described.

38. The combination in a calculating-machine of a series of numeral-wheels, a series of oscillating carrying-teeth and mechanism for oscillating the two series with respect to each other, whereby the numeral-wheels are in working position with the carrying-teeth during the oscillation of the latter in one direction, but are all removed from working position during their return oscillation, substantially as described.

39. The combination in a calculating-machine of a series of reciprocating adding-gears, a series of oscillating numeral-wheels, and a series of oscillating carry-teeth, whereby the numeral-wheels are in working position with the adding-gears during their motion in one direction and are put into working position with the carry-teeth during the return motion of the said gears, substantially as described.

40. The combination in a calculating-machine of a series of adding-gears and an adding-carriage, means for adjusting and means for locking the adding-gears in adjusted position in the addiag-carriage, a series of numeral-wheels, mechanism to move the addiag-carriage with respect to the series of numeral-wheels, and mechanism to move the series of numeral-wheels into position to mesh with the series of adding-gears and to remove them from that position at fixed points in the motion of the adding-carriage, whereby the adding-gears and numeral-wheels are in meshing position during a limited and fixed part of the motion of the adding-carriage, and the adding-rack is in actual mesh with the numeral-wheel during an adjusted and limited part of that motion, substantially as described.

41. The combination in a calculating-machine of a series of adding-racks and an adding-carriage, means for adjusting and means for locking the addieg-gears in adjusted position in the adding-carriage, a series of numeral-wheels, mechanism to give the addieg-carriage a reciprocating motion with respect to the series of numeral-wheels through a limited and fixed distance, and mechanism to move the series of numeral-wheels into position to mesh with the adding-racks and to remove them from that position at fixed points in the motion of the adding-carriage whereby the adding-gears and numeral-wheels are in meshing position during a limited and fixed part of the reciprocating motion of the adding-carriage, and the adding-rack is in actual mesh with the numeral-wheel during an adjustable and limited portion of that motion, substantially as described.

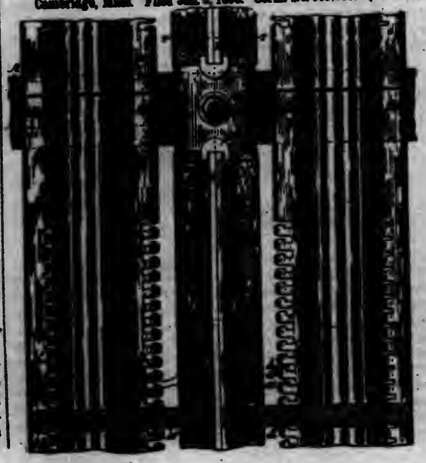
42. The combination in a calculating-machine of the shaft 45 rotatable in bearings in the numeral-carriage 6, the zero-setting crank 55 and the detent 56 by which the shaft and crank are fixed to the numeral-carriage, the series of numeral-wheels 44 on the shaft 45, the carrying-pins 50 on the numeral-wheels, and the series of carrying-levers 51 yielding to the motion of the numeral-wheels upon the shaft in one direction and holding against their motion in the other direction, whereby the carrying-levers strike the carrying-pins and hold the numeral-wheels when the shaft is turned by means of the zero-setting crank, and the wheels are set to zero by means of the same carrying-levers and carrying-pins that act in the operation of the carriage of tens, substantially as described.

43. The combination in a calculating-machine of an oscillating numeral carriage laterally adjustable in guides, an index-bar separate from the numeral-carriage and laterally adjustable in guides, and mechanism connecting the numeral carriage and the index-bar, whereby the numeral-carriage and the index-bar receive a simultaneous lateral adjustment, substantially as described.

605,289. KNIFE, SCISSORS, OR SKATE SHARPENER. MOSES L. HAWES, Chicago, Ill. Filed Oct. 30, 1897. Serial No. 656,966. (No model.)

Claim.—The herein-described sharpener consisting of the bracket, A, having a hardened metal sharpening-disk pivotally secured thereto, the bracket being cut away at the top forming the aperture, D, the line at one side being perpendicular to the base and adapted to the sharpening of skates, and that of the opposite side forming an acute angle adapted to the sharpening of scissors and shears, with the inclined notches at the sides adapted to the sharpening of knives, all substantially as set forth.

605,290. MACHINE FOR WRINGING CLOTHES. JAMES HEMMINGWOOD, Leeds, England. Filed Dec. 23, 1897. Serial No. 663,165. (No model.) Patented in England May 22, 1897, No. 12,716.



Claim.—1. The combination with the two rollers in a wringing-machine and a feed-board to the same, of the rocking frame E having trunnions at the ends, the brackets G for supporting the rocking frame, the fingers H and stop-hinges for connecting the fingers to the rocking frame and a handle for turning the rocking frame, substantially as set forth.

2. The combination in a machine for wringing clothes with the two rollers and a flange at the end of the lower roller, of a tangential plate and two arms supported on the axle of the upper roller and resting on the flanges of the lower roller and carrying such tangential plate and a weight to keep the inner edge of the tangential plate in contact with the surface of the upper roller, substantially as set forth.

3. The combination in a wringing-machine having two rollers and a feed-board, of a rocking frame E and trunnions for the same, fingers and stop-hinges for connecting the fingers to the rocking frame, a handle for turning the rocking frame and a tangential plate and arms for suspending the same with the edge of the tangential plate adjacent to the surface of the upper roller, substantially as set forth.

605,291. LIBRARY SHELVING, STACK, &c. DAVID B. HUSTED, Cambridge, Mass. Filed Jan. 4, 1898. Serial No. 665,793. (No model.)

Claim.—1. A library-standard having adjacent its vertical edges longitudinal projections rigidly spaced apart and each provided with a series of transverse notches in its rear edge, the respective notches of the two projections being in substantial horizontal alinement, and the rear notches having engaging shoulders, said notches being adapted to receive shelf-lugs slid into them horizontally from the rear, and locked therein by dropping into engagement with said shoulders, substantially as described.

2. A library-standard comprising a central web having at its edges longitudinal projections or beads, the front projection having a series of horizontal notches formed therein on its rear edge at each side of said web, and the rear projection having a series of notches cut transversely thereof across its rear edge, the latter series of notches containing locking-offsets in their lower sides, substantially as described.

3. A library-standard composed of sheet metal rolled over at its opposite vertical edges to form hollow beads or projections, the front roll having on its opposite sides at the rear part of the roll opposite series of horizontal notches, and the rear roll having at its rear part and extending into its opposite sides series of horizontal notches, the said notches having flaring lips at their rear ends for the ready reception of shelf-lugs, substantially as described.

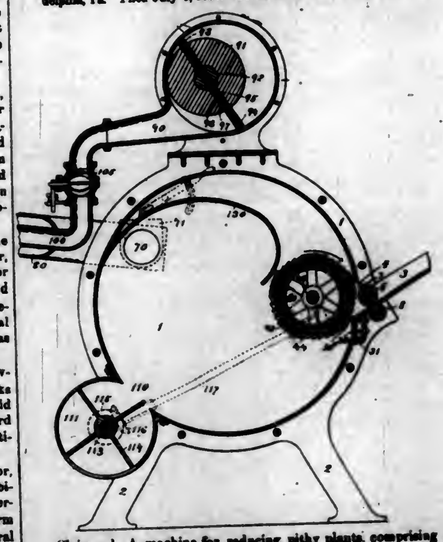
4. A support for library-shelving comprising opposite standards, shelves to be supported thereby, said shelves having adjacent their four corners fixed lugs projecting therefrom, and said standards having recesses with openings at the rear only for the reception of said lugs, whereby a shelf is put in position by forward movement from the rear and is removed by movement toward the rear, certain of said recesses having offsets and shoulders to receive and engage certain of said lugs and lock the shelf in position when properly placed, substantially as described.

5. In a library-stack, a plurality of standards for supporting the shelves, said standards being arranged vertically one above the other, floor-beams in pairs, said standards being rigidly clamped at their upper ends between said floor-beams and extending loosely between said floor beams at their lower ends, and means to prevent lateral movement in any direction of said lower ends while permitting vertical movement due to contraction and expansion thereof, substantially as described.

6. In a library-stack, a standard for supporting the shelves, having hollow rolls or beads at its opposite vertical edges, filling-blocks rigidly clamped in said rolls at the upper ends of said standard, said filling-blocks having reduced portions projecting above said standard adapted to receive the lower end of a similar standard placed vertically thereabove, substantially as described.

7. In a library-stack, horizontal floor-beams, separators therefor, clamping-blocks engaging said beams on their outer sides, in combination with supporting-posts vertically alined, said blocks having vertical projections at their top and bottom sides to inclose and form pockets for the said posts, retaining the latter from relative lateral displacement, and means to clamp said blocks and beams together, substantially as described.

8. In a library-stack, horizontal floor-beams, separators therefor, clamping-blocks engaging said beams on their outer sides, said blocks having inwardly-projecting ledges on which said beams may rest, in combination with supporting-posts vertically alined, said blocks having vertical projections at their top and bottom sides to inclose and form pockets for the said posts, retaining the latter from relative lateral displacement, and means to clamp said blocks and beams together, substantially as described.

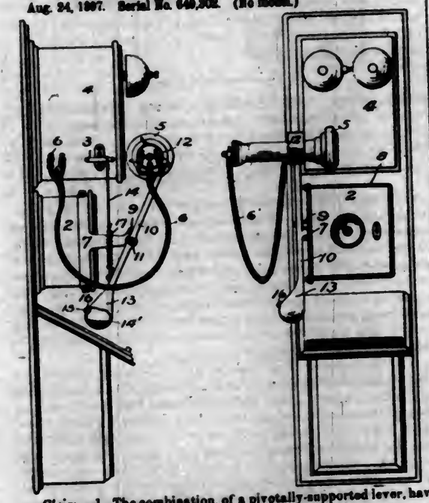


605,292. BUTTON. NATHAN D. INGRAM, Holyoke, Mass. Filed Aug. 9, 1897. Serial No. 647,541. (No model.)

Claim.—1. A detachable button consisting of a body comprising a face and a rear-side collet, having a clear space therebetween, said collet having two parallel transverse slots therethrough, near the center of said collet, and two other slots in line with the former terminating by one end within the border-bead of said face, and a loop-catch on its inner surface, combined with a transversely-movable, wire, button-attaching element having a looped end contained within said body, having a part for engagement with said loop-catch, and button-attaching hooks extending in curved lines from said looped end through two of said slots and near to said border-bead for engagement therewith within the ends of said last-named slots, substantially as set forth.

2. A detachable button consisting of a body comprising a face and a rear side collet, having a clear space therebetween, said collet having two parallel transverse slots therethrough, near the center of said collet, and two other slots in line with the former, terminating by one end within the border-bead of said face, and a loop-catch on its inner surface, combined with a transversely-movable, wire, button-attaching element having a looped end contained within said body, having a part for engagement with said loop-catch, and button-attaching hooks extending in curved lines from said looped end through two of said slots and near to said border-bead for engagement therewith within the ends of said last-named slots, and having shoulders thereon for engagement with a border of the last-named slots, substantially as set forth.

605,298. MACHINE FOR REDUCING PITHY PLANTS. ALBERT F. MADDEN, Newark, N. J., assignor to the Marsden Company, Philadelphia, Pa. Filed July 8, 1897. Serial No. 643,810. (No model.)



Claim.—1. A machine for reducing pithy plants, comprising a separating-chamber having an opening for the passage of plant material, feeding and supporting devices adjacent to said opening for feeding the plant material through the opening and supporting it in position to be operated upon by the disintegrator, a rotary disintegrator having alternate groups of cutting-teeth and wire brushes, and an air-ejector communicating with the upper part of the separating-chamber to remove the lighter parts of the disintegrated plant, said separating-chamber having an opening in its lower part for the removal of the disintegrated fiber.

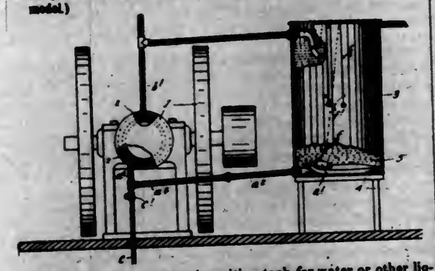
2. In a machine for reducing pithy plants, the combination of a separating-chamber, a disintegrating mechanism discharging into the separating-chamber, an outlet adjacent to the bottom of the separating-chamber for the discharge of the heavier particles, an outlet adjacent to the top for the discharge of the lighter particles, air-exhausting mechanism communicating with the outlet for the lighter particles, a valve controlling the air-exhausting mechanism, and a suitable valve controlling the said exhaust-outlet for lighter particles, as set forth.

3. A machine for reducing pithy plants, comprising an approximately cylindrical separating-chamber, an inlet-opening for the plants, a disintegrating mechanism in the separating-chamber into which the plants are fed through the inlet, an outlet for heavier particles in the lower part of the separating-chamber, and a shield or guard within the separating-chamber extending from the exhaust-outlet partially around the disintegrating mechanism, as set forth.

4. A machine for reducing pithy plants, comprising a disintegrating roll or cylinder having a series of cutting-teeth and wire brushes arranged alternately circumferentially upon the periphery of the roll or cylinder, the brush-wires extending radially beyond the working edges of the cutting-teeth, and an adjustable plate upon which the plants are supported against the action of the disintegrating-roll, as set forth, in combination with a chamber containing said disintegrating-roll and having an opening through which fibrous plant material may be fed to the disintegrator, and an air-ejector communicating with the upper part of said chamber.

605,294. TELEPHONE-HOLDER. JESSE T. MOORE, Minneapolis, Minn., assignor of one-half to Harry L. Jenkins, same place. Filed Aug. 24, 1897. Serial No. 649,202. (No model.)

Claim.—1. The combination, of a pivotally-supported lever, having a balance-weight on one end and a telephone-receiver clasp on the other end, with a telephone-switch-operating connection, substantially as described.



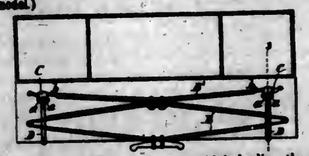
2. The combination, of a plate, arm, or bracket, with a lever pivoted thereon, one end of said lever being provided with a weight to counterbalance a telephone-receiver on the opposite end of said lever, whereby when said receiver is freed, the same will be lifted automatically, substantially as described.

3. The combination of the support, with a lever pivoted to swing freely thereon, said lever having a clasp, or holder, on one end for a telephone-receiver, and having a weight-holder on its opposite end and a telephone-switch connection, substantially as described.

4. The combination, with a plate, arm, or bracket, provided with a lever-stop, of a lever pivoted upon said bracket, said lever having a telephone-receiver, clasp, or holder, upon its outer end, and having an adjustable weight upon its inner end, and, a telephone switch connection upon said inner end of the lever, substantially as described.

5. The combination, of a plate, arm, or bracket, with a lever pivoted thereon, a receiver-clasp upon the outer end of said lever, a hollow weight-holder upon the inner end of said lever, and a yielding or adjustable switch connection, substantially as described.

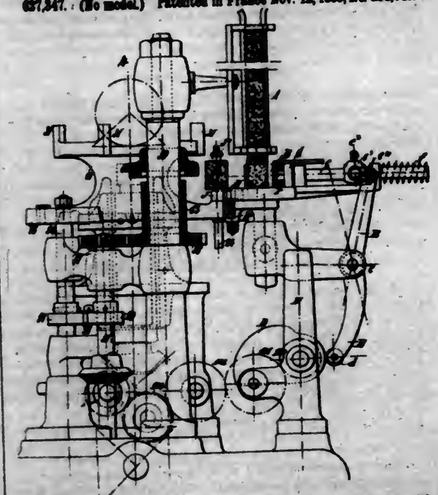
605,295. DRAINABLE PIPE FOR TANKS. THOMAS J. MURPIN, Sleepy Eye, Minn. Filed Dec. 14, 1897. Serial No. 661,832. (No model.)



Claim.—1. The combination with a tank for water or other liquids, of a pipe having, within the tank a section normally submerged, but capable of extension to a point above the liquid-level in the tank, for draining the pipe without emptying the tank, substantially as described.

2. The combination with a tank and an engine having a water-jacket, of circulating connections from said tank to said jacket, which circulating connections include sections of pipe within the tank normally submerged, but capable of extension to a point above the liquid-level, and a discharge-opening, outside the tank, for draining the circulating connections in the water-jacket of the engine, without emptying the tank, substantially as described.

3. The combination with a water-tank and a water-jacketed engine, of circulating connections from the tank to the engine, which connections are provided with flexible sections of pipe within the tank normally submerged, but capable of being elevated to bring their mouths above the liquid-level in the tank, and a valve-controlled discharge-opening, at the lowest point in the circulating connections outside the tank, substantially as and for the purposes set forth.



605,296. SPRING-HANGER FOR VEHICLE-BODIES. JAMES McCAUSEEN, Pontiac, Mich. Filed June 24, 1897. Serial No. 642,022. (No model.)

Claim.—1. In a spring-hanger for vehicle-bodies, the combination with the cross-spring, of the hanger having a socket in which the end of said spring is secured, said hanger also having the depending lugs, the body-loop attached to the vehicle-body at one end and pivoted at the other end between the lugs of said hanger.

2. In a spring-hanger for vehicle-bodies consisting of an integral head or hanger having a horizontal socket to receive the end of a cross piece or spring and provided with opposed depending lugs between which the end of the body-loop may be pivoted.

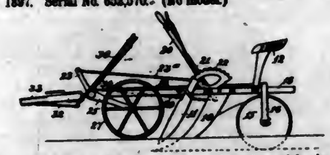
605,297. MACHINE FOR CUTTING CORKS. CHARLES HOLL, Paris, France, assignor to La Société Industrielle du Liège et de La Bouchonnerie Parisienne, same place. Filed Mar. 13, 1897. Serial No. 627,347. (No model.) Patented in France Nov. 12, 1896, No. 261,648.

Claim.—1. In a machine for cutting corks, the combination, with a carrier and guide mechanism for the cork blocks, of an intermittently-rotating platform provided with four pairs of equidistant grippers, two endless cutting-blades arranged at right angles to each other and adapted to act successively on said blocks, horizontal rotary trimming-knives acting on the block after the third stop, and clamping-holders for delivering the cork from the grippers and supporting it for the action of the trimming-knives, substantially as set forth.

2. In a machine for cutting corks, the combination, with a guide-frame for feeding the cork blocks, of a horizontal guideway for re-

ceiving the cork blocks, a horizontal reciprocating pusher-plate for feeding the cork blocks forward to the grippers, a spring-pressed side plate connected with and reciprocating with said pusher-plate, and means for intermittently actuating said plates, substantially as set forth.

3. In a machine for cutting corks, the combination, with an intermittently-rotating platform provided with a series of upper and lower grippers arranged in pairs, each of the lower grippers having a screw-spindle provided with thread of slow pitch, a vertically-guided screw-sleeve surrounding and engaging said threaded spindle, and an intermittently-rotating cam actuating said sleeve so as to impart rotary motion on its axis to the lower gripper and by the cork block to the upper spindle, substantially as set forth.



4. In a machine for cutting corks, the combination, with an intermittently-rotating platform, said rotating platform having four pairs of grippers for holding the cork blocks, means for releasing the cork blocks from the grippers, clamping-holders for transferring the corks from the grippers, a pair of horizontal parallel trimming-knives for cutting off the ends of the corks delivered to said holders, and means for releasing the corks from the holders after they are trimmed, substantially as set forth.

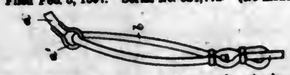
5. In a machine for cutting corks, the combination, with an intermittently-rotating platform having pairs of grippers, means for intermittently arresting and locking said platform, a pair of rotary clamping-holders moving into the path of the cork, means for actuating the grippers so as to release the corks to said holders, a pair of horizontal parallel trimming-knives for cutting off the ends of the corks, and means for releasing the corks after the same have been trimmed at the ends, substantially as set forth.

6. In a machine for cutting corks, the combination, with a supporting-frame, a power-driven shaft stepped in said frame, an intermittently-rotating platform sleeved on said power-shaft and supported by said supporting-frame, means for locking the platform after each partial rotation, a large gear carried by said platform, a small gear carried by the said power-shaft and nested in said large gear, a combined full and mutilated gear the full teeth meshing with the small gear and the mutilated teeth meshing with the large gear whereby an intermittent rotation is imparted to said platform, substantially as set forth.

7. In a machine for cutting corks, the combination with a pillar, of a gear-wheel provided with a sleeve loosely mounted on said pillar and provided with springs two extensions carried by said sleeve and terminating in holders, grooved clamps working in said extensions, and a cam-faced piece fixed on said pillar above the said sleeve and adapted to operate said clamps in one direction, said springs being adapted to operate the clamps in the reverse direction, substantially as set forth.

605,298. SULKY-PLOW. WILLIAM H. PERRIN, Smith's Falls, Canada, assignor of one-half to John R. Lavell, same place. Filed Sept. 23, 1897. Serial No. 652,570. (No model.)

Claim.—1. In a sulky-plow, the combination with the axle 25ª having depending arms at the ends on which the wheels are journaled, an arm 23 secured to the said axle, a lever fulcrumed on the plow-beam attached to the said axle, a toothed segment and spring-catch holding the said lever in any desired position, a rod connecting the said lever to the said arm 23, above the fulcrum, and a chain connecting the said lever below the fulcrum with a hook on the said axle, substantially as set forth.



2. In a sulky-plow, the combination with the axle 25ª on the depending arms of which the front wheels are journaled, of the tongue pivotally connected to the said axle, the lever 30 fulcrumed on a rod 31, a toothed segment adapted to be engaged by the said lever and secured to the said axle, and a brace-rod 32, pivoted to the said lever below the fulcrum and to the tongue a short distance from its rear end, substantially as set forth.

605,299. CORSET-SHIELD. MARIE L. PERROTTET, New York, N. Y. Filed Oct. 22, 1895. Serial No. 566,551. (No model.)

Claim.—A corset-shield consisting of two inner superimposed layers of soft projecting material having a series of separated pockets; a series of parallel non-resilient pliable strips disposed one in each of said pockets, and all extending in the same direction, and an outer covering of soft material completely inclosing said inner material and strips, whereby when the shield is bent the strips will retain said shield in its bent position.

605,300. STRAP-FASTENER. GEORGE S. SARGIS, Bloomfield, N. J. Filed Feb. 3, 1897. Serial No. 621,772. (No model.)

Claim.—1. The improved parcel-fastener herein described, comprising a strap, a plate with ears projecting laterally from the opposite longer sides thereof, the ears on one of said sides being bent downward and inward toward the central longitudinal axis of said plate, and permanently clamping one end of said strap against the under surface of said plate, and the two ears on the opposite side being bent upward and inward toward the central longitudinal axis of the plate and forming hooks overlying said plate, and a keeper-stud projecting upward from the surface of said plate and having a biting edge to engage said strap, substantially as set forth.

2. The improved parcel fastener herein described, comprising a plate of sheet metal having a flat oblong body portion, the opposite longitudinal edges of which are provided with ears lying to or near the opposite extremities of said body portion, said ears projecting outwardly from said edges and being returned substantially parallel to the plane of said body portion, the ears *d*, *d*, of one edge being bent toward the opposite surface of the body portion from that toward which the ears *c*, *c*, of the opposite edge are turned, a tongue struck up from the central part of the body portion and forming a keeper-stud *f*, which stands at a point about midway between the returned ears *c*, *c*, with its plane at substantially right angles to the longitudinal axis of said body portion, substantially as set forth.

605,301. TICKET-CASE. NELSON R. SPRINGSTEEN, Royal Oak, Mich. Filed Oct. 25, 1897. Serial No. 656,574. (No model.)

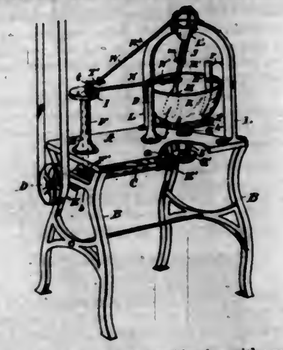
Claim.—1. A ticket-case comprising a casing and cover, partitions therein forming receptacles for the ticket-rolls, a pin or shaft passing through the center of a roll, and friction-springs on the sides of each receptacle bearing against the sides of the roll, and constituting bearings for the roll-shaft, to give tension to the unwinding.

2. A ticket-case comprising a casing and cover, partitions therein forming receptacles for the ticket-rolls, a pin or shaft passing through the center of a roll, friction-springs on the sides of the receptacle bowed out at the middle to bear against the side of the roll, and longitudinal slots in the springs from the end to at or near the middle, forming entering slots and bearings for the shaft of the roll, substantially as described.

3. A ticket-case comprising a casing and cover, a receptacle for a ticket-roll, friction devices for retarding the unwinding of the roll, a toothed wheel over which the ticket-strip passes, and a bell-ringing mechanism adapted to be operated by the wheel upon the drawing thereover of a length of paper equal to the length of a ticket, and means for guiding said ticket-strip and holding a portion thereof exposed whereby it can be engaged for the purpose of drawing the ticket-strip out.

4. A ticket-case comprising a casing, a cover, and a ticket-roll receptacle, a toothed wheel opposite the receptacle guides for the paper around the wheel so as to lead the paper off from the wheel in a plane at an acute angle to the entering place, and a bell-ringing mechanism operated by the wheel upon the drawing over the same a length of paper equal to the length of a ticket, and means for guiding said ticket-strip and holding a portion thereof exposed whereby it can be engaged for the purpose of drawing the ticket-strip out.

5. In a ticket-case, the combination of the casing, having a roll-compartment and a trough-shaped section L, a wheel journaled to



have its periphery project through a slot in this section L, a cover having a hooked section adapted to inclose the trough-shaped section to leave a guideway for the paper between, and guides on the casing for the edges of the strip beyond this guide under the hooked edge of the cover.

6. In a ticket-case the combination of the casing having a ticket-roll compartment therein and a trough-shaped section, a wheel journaled to have its periphery project through a slot in this section L, a cover having a hooked section adapted to inclose said trough-shaped section and leave a guideway for the ticket-strip between, and the finger or bar T on the cover adapted to press the strip into contact with said trough-shaped section for the purpose described.

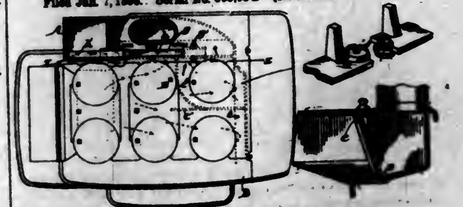
7. A ticket-case comprising a casing having a receptacle therein for a plurality of ticket-rolls friction devices for retarding the unwinding of said rolls, a toothed wheel for each roll over which the ticket-strip is led, and a single bell-ringing device adapted to be operated by the drawing over any one of said wheels a length of strip equal to one ticket.

8 A ticket-case comprising a casing having receptacles therein for a plurality of ticket-rolls, friction devices for retarding the unwinding of said rolls, toothed wheels for said rolls over which the ticket-strips are led, a common shaft to which said wheels are secured, a bell adapted to be sounded by the turning of said shaft caused by the drawing over of any one of said wheels a length of strip equal to one ticket, and guides for holding said strip so as to be unaffected by the turning of said wheels but allowing said strip to be free to engage with said wheels when drawn out from the case.

605,302. TRITURATOR. CHARLES L. TREMLER, Indianapolis, Ind. Filed Nov. 14, 1896. Serial No. 612,092. (No model.)

Claim.—1. In a triturator, the combination, with a revolving support and a mortar detachably secured thereto, of a rotary swinging pestle adapted to traverse the inner surface of the mortar, the longitudinal axis of the pestle being always approximately at right angles to the surface of the mortar at the point of contact, a crank-wheel and a pestle-lever connected with and actuated by the crank-wheel and provided with a pivotal bearing through which longitudinal movement of the pestle-lever is permitted and said pestle-lever having a hinge-joint permitting vertical movement and a swivel-joint permitting rotary movement, the axis of revolution of the mortar being out of alinement with the centers of the crank-wheel and pivotal bearings of the pestle-lever, all substantially as described and for the purposes specified.

2. In a triturating-machine, the combination with a revolving mortar and a rotary swinging pestle, of a pulley supported above the pestle, a wrist-pin having a horizontally-pivoted bar and a vertical pin to engage the bar and force it around during part of each circuit of revolution of the wrist-pin and a cable or chain passing over the pulley and having one end connected by means of a swivel with the pivoted bar and having the other end of the chain connected with the top of the pestle-handle, all substantially as described and specified.



3. In a triturating-machine, the combination, with a revolving mortar, a pestle having rotary swinging movement and mechanism for actuating the mortar and pestle, of means consisting of a pulley elevated above the pestle, a cable or chain passing over the pulley and connected at one end to the pestle and at the other end to mechanism substantially as described, which will alternately pull on the chain or cable and then release it, whereby the pestle will be raised and lowered.

4. The combination, with a revolving mortar of a funnel-shaped collar above and at one side of the center of the mortar, a pestle traversing the inner surface of the mortar in an epicycloidal path and having a stem or arm projected up through the funnel-shaped collar, an adjustable collar on the pestle-arm, a spiral spring on said arm between the funnel shaped and the adjustable collar, and means, substantially as described, for compressing the spring and elevating the pestle and then releasing it suddenly whereby a pounding movement will be imparted to the pestle, all substantially as and for the purposes specified.

5. A cover for mortars having an opening through which the pestle-arm will be projected, said cover being split from its outside edge into the opening for pestle-arm, and having the edges made by said split, bent whereby they can be joined by hooking them together.

6. In a triturating-machine, the combination, with a revolving mortar, a pestle having rotary swinging movement and mechanism for actuating the mortar and pestle, a wrist-pin moving in a circular path, a horizontal bar pivoted to the wrist-pin, and a vertical pin to engage the bar and force it around during part of each circuit of revolution of the wrist-pin, of means consisting of a pulley elevated above the pestle, a cable or chain passing over the pulley and connected at one end to the pestle and at the other end to the horizontal bar, said cable or chain having an elastic portion whereby the length of the cable or chain can be increased within predetermined limits, all substantially as described and specified.

605,303. COOKING-STOVE. ARTHUR W. WALKER, Malden, Mass. Filed Jan. 7, 1898. Serial No. 665,934. (No model.)

Claim.—1. In a stove, a wall interposed in the path of the smoke from the fire to the smoke-pipe and provided with two openings, combined with one damper to substantially cover either or both said openings, substantially as described.

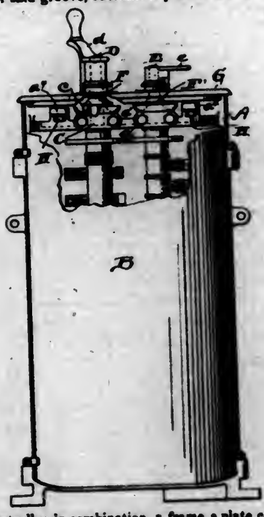
2. In a stove, an inclined partition or wall located in the path of the smoke from the fire to the smoke-pipe, and provided with a direct-draft opening and a baking-draft opening, combined with one damper coöperating with both said openings, substantially as described.

3. In a stove, an inclined partition or wall located in the path of the smoke from the fire-box to the smoke-pipe, said wall being provided with a direct-draft opening and a baking-draft opening and having a groove at the base of said partition or wall, combined with a damper, the lower edge of which enters and slides in said groove, said damper resting by its gravity on and being free to slide on said partition or wall, substantially as described.

4. The combination with a stove provided with a slot for a damper-knob, and a damper located below said slot, of a damper-operator composed of a jointed two-part bar coöperating with said damper to move it and at the same time keep said slot closed, substantially as described.

5. The combination with a stove, of a damper having a lug, combined with a damper-operator made as a sliding bar having two fingers embracing said lug, substantially as described.

6. A stove having a straight longitudinal partition or wall provided with a direct-draft opening and a baking-draft opening arranged side by side, and other walls c^4 and c^5 to form flues, combined with a damper moving against one side of said partition and means to move it in a straight line to cover or to uncover the direct-draft opening and uncover more or less of the baking-draft opening, substantially as described.



605,304. CONTROLLER. THORSTEN VON ZWIEDENECK, Cleveland, Ohio, assignor to the Walker Company, same place. Filed Feb. 23, 1898. Serial No. 671,238. (No model.)

Claim.—1. In a controller, the combination with the controller-shaft of a collar tightly surrounding the shaft and a trough below the collar and adapted to receive water passing from it and convey it beyond the controller, substantially as described.

2. In a controller, the combination with the controller-frame, the top plate, and the controller-shaft projecting through that top plate, of a collar tightly surrounding the shaft below the top plate, and a trough below the collar adapted to receive water passing from it and convey it outside of the controller, substantially as described.

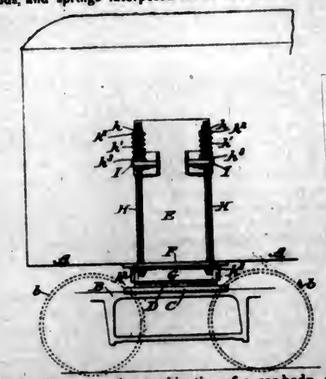
3. In a controller, the frame A, the plate *a*, the cap-block C form-

ing a portion of the bearing for the controller-shaft, said cap-block having a U-shaped groove in its upper side terminating over the plate *a*, in combination with the controller-shaft carried in such bearing and a collar tightly secured to the shaft above the bearing and having its edge over said groove, substantially as described.

4. In a controller, in combination, a frame, a plate carried thereby near its upper end, a bearing at the front of said plate, a shaft in said bearing, means for conveying water trickling down the said shaft to said plate, and an orifice leading from said plate, substantially as described.

5. In combination, the frame A, the plate *a* projecting forward from the rear side of the controller, the wall *a'* around the front and ends of said plate, the opening a^2 at the rear of said plate, a cap-block C secured at the front of said plate and forming therewith a bearing for the controller-shaft said cap-block extending rearward over said plate, a U-shaped groove on the upper side of the said cap-block, and a flaring collar surrounding the shaft and extending over said U-shaped groove at its forward side and over said plate *a* at its rear side, substantially as described.

6. The combination, in a controller, of a frame, a plate *a* carried thereby near the upper end of the frame, a top plate G above the plate *a*, a packing between said top plate and the top of the frame, a shaft journaled within the controller and projecting through said top plate, means for conveying water passing through the plate G around the shaft from the shaft to the plate *a*, and an exit-orifice for the water from said plate *a*, substantially as described.



7. The combination, in a controller, of a frame A, a plate *a* projecting forward therefrom, a wall *a'* around the front and sides of said plate, a lug a^4 carried by the said plate, a top plate G secured to said lug, and packing J between said top plate and the top of the frame, a bearing carried by said plate *a*, a shaft journaled therein and projecting through said plate G, and means for conveying water trickling down the shaft from the shaft to the plate *a*, substantially as described.

605,805. RAILWAY-CAR. WILLIAM L. AUSTIN, Philadelphia, Pa., assignor to himself, George Burnham, Edward H. Williams, William P. Henneey, John H. Converse, Samuel M. Vauclain, Alba B. Johnson, and George Burnham, Jr., same place. Filed Mar. 7, 1896. Serial No. 672,534. (No model.)

Claim.—1. In a railway-car, the combination of a car-body, a truck swiveled upon a central guide, and suspension-hangers connected to said central guide and to the floor of the car-body and by which said body is supported from said truck.

2. In a railway-car, the combination of a car body, a truck, a support resting centrally upon said truck and projecting through and above the floor of the car-body and suspension-hangers connected at their upper ends to said support and carrying the car-body at their lower ends.

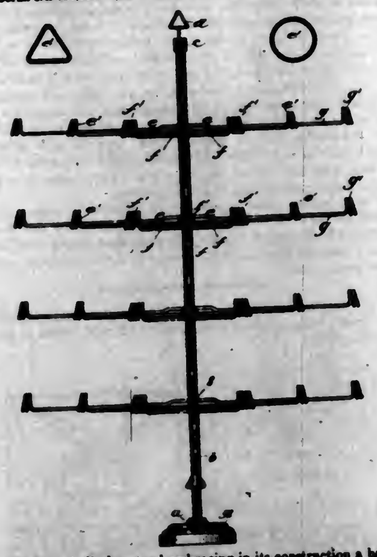
3. In a railway-car, the combination of a car-body, a truck, a support resting centrally upon said truck and projecting through and above the floor of the car-body, suspension-hangers connected at their upper ends to said support and carrying the car-body at their lower ends, and springs interposed between said hangers and the support.

4. In a railway-car, the combination of a car-body, a truck, a support resting centrally upon said truck, suspension-hangers connected to said support and carrying the car-body, and ball-joint bearings interposed between the support and the hangers and between the hangers and the car-body.

5. In a railway-car, the combination of a car-body, a truck, a support resting on said truck, a plate secured to the car-body and having a collar to fit about the support, suspension-hangers connected at their upper ends to said support and at their lower ends to said plate, the contact-surface of said collar being rounded.

6. In a railway-car, the combination of a car-body, a truck, a boiler resting on said truck, and suspension-hangers connected to said boiler and carrying the car-body.

7. In a railway-car, the combination of a car-body, a truck, a boiler resting on said truck, suspension-brackets secured to said boiler, and suspension-hangers connected to said brackets and supporting the car-body at their lower ends.



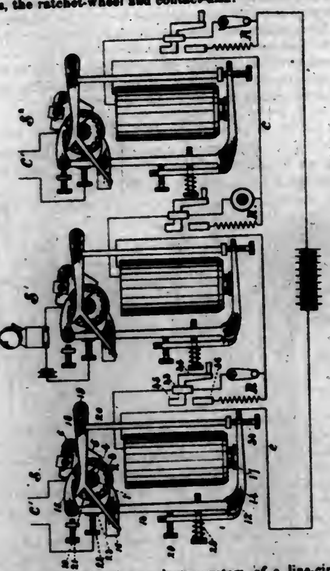
605,806. ADJUSTABLE FURNITURE. GABRIEL A. BOSSICK, Boston, Mass. Filed Dec. 26, 1896. Serial No. 616,963. (No model.)

Claim.—1. An adjustable support or standard for furniture, comprising a lower member adapted to be rigidly secured to the floor, a movable member adapted to be secured to the article of furniture and sliding on the fixed lower member, the adjacent faces of said members being parallel to the direction of adjustment of the furniture, a clamping device between which and the member of the standard to which it is attached the other member is locked, said latter member being wedge shaped, and means to prevent movement of the said member opposite to the direction of taper of the wedge, substantially as described.

2. An adjustable support or standard for furniture, comprising a lower member adapted to be rigidly secured to the floor, a movable member adapted to be secured to the article of furniture and sliding on the fixed lower member, the adjacent faces of said members being parallel to the direction of adjustment of the furniture, a clamping device between which and the member of the standard to which it is attached the other member is locked, said latter member being wedge-shaped and having a toe or projection thereon, and a vertical series of teeth formed on the fixed member, engagement of the toe with a tooth preventing displacement of the movable member opposite to the direction of taper of its wedge, substantially as described.

605,807. DISPLAY-STAND. GEORGE H. DURGIAN, Lawrence, Mass., assignor to Elizabeth Rogers, Lynn, Mass. Filed Mar. 17, 1897. Serial No. 627,868. (No model.)

Claim.—A display-stand embracing in its construction a base, a standard extending up from the base, radial arms *c*, *f*, *g*, screwed at their inner ends into the standard and provided on their outer ends with clip-coils, the shank of the arms *c* extending through the clip of the arm *f*, and the shank of the arm *g* extending through the clips of the arms *c* and *f*, as set forth.



605,808. CYCLIST'S POUCH. PERCY W. DEACON and ADOLF TIEPE, Manchester, England. Filed Dec. 20, 1896. Serial No. 617,436. (No model.) Patented in England June 12, 1896, No. 13,056.

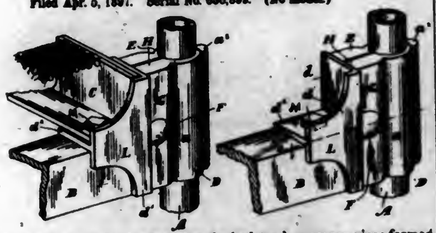
Claim.—A cyclist's pouch consisting of and comprising an oblong strip of leather forming the outer part of the pouch, a transverse strip sewed thereon in such a manner as to produce a pocket between the two strips, holders or receptacles on the transverse strip such as *c c'* and D, flaps on the transverse strip to fold over said holders, and a pocket E formed on the lower part of the outer oblong strip which folds over at each end above the flaps of the transverse strip, together with straps and buckles for securing the pouch and for attaching it to the machine.

605,809. ELECTRIC SELECTOR SYSTEM. THOMAS C. DRAKE, Malta, Ohio. Filed Feb. 26, 1897. Serial No. 624,260. (No model.)

Claim.—1. The combination of a series of step-by-step mechanisms and a series of restoring mechanisms at a series of stations respectively, means for moving the series of stepping mechanisms to a predetermined position by an intermittent current, and means for operating the restoring mechanism to return the parts to normal by a current of greater strength than the intermittent current, the stepping and unison mechanisms comprising a magnet, angle-lever and armature, the vertical lever and pawls, the stress-spring to combine the levers, the ratchet-wheel and contact-disk.

2. The combination in a selector system, of a line-circuit connecting a series of step-by-step and restoring mechanisms at a series of stations respectively, an operating-battery located in said circuit, a series of contact-cranks, and a series of switches located at said stations by means of which the said circuit may be opened and closed, and the current pulsated through the mechanisms, means located at each station, by which the normal current in the line-circuit may be diminished when it is desired to step the mechanisms, and restored when it is desired to restore the mechanisms, the step-by-step and restoring mechanisms comprising the ratchet-wheel, levers and pawls, to rotate the contact-disk when pulsating the diminished current, the contact-disk and contact-screw to close the signaling-circuit at a predetermined position of rotation of said series of mechanisms, the bifurcated lever operated by the said normal current to disengage the pawls, and the segment-gear to return the ratchet-wheel and contact-disk to normal position on operating the restoring mechanisms to reset the system.

3. The combination with vertical lever 13, the angle-lever and armature, the contact-screw 22, insulated therefrom, of the retractile spring 24, in electrical connection with said contact-screw, and insulated from said levers to form a conductor for circuit C', substantially as specified.

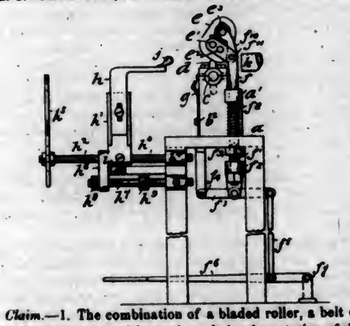


4. In a selector system, the combination of the electromagnet and armature, the vertical lever to step the ratchet-wheel, the angle-lever, stress-spring and suitable adjustments, the shaft 1, ratchet-wheel 2, contact-disk 3, pinion-gear 4, the pointer 7, the weighted segment-gear to return the revolving parts to normal position, the bifurcated lever and its lifting-rod to disengage the pawls from the teeth of the ratchet-wheel, the contact-screw 22, and contact-segment of disk 3, to close the circuit C', substantially as specified.

5. In a selector system the combination at each station of the face plate and pointer, the ratchet-wheel, pawls and lever to step the contact-disk, the contact-disk and contact-screw to close the circuit C', the bifurcated lever and lifting-rod operating through the influence of the electromagnet to disengage the pawls, the pinion-gear and segment-gear to return the pointer, ratchet-wheel and contact-disk to normal position, the electromagnet, angle-lever and armature operating under the influence of the diminished current to step the ratchet-wheel, and operating under the influence of the normal current to disengage the pawls from the teeth of the ratchet-wheel, the stress-spring and its adjusting-screw, the resistance to diminish the current, and means of keeping said resistances normally out of circuit, substantially as set forth.

6 In a selector system, the combination of a plurality of devices connected in series with suitable source of current, each of said de-

vices consisting of an electromagnet and armature, a shaft carrying a ratchet-wheel, contact-disk, pointer and pinion-gear, the angle-lever, vertical lever and strem-spring with its adjustments, pawls carried on said vertical lever to step said ratchet, a contact carried by said vertical lever to make contact with said disk, a bifurcated lever to disengage the said pawls from the teeth of said ratchet-wheel, a weighted segment-gear meshing with said pinion-gear to return said ratchet-wheel, contact-disk and pointer to normal position, a resistance located at each of said devices to diminish the current in circuit C, for the purpose specified, and means as described to make the current intermittent through the system.



605,810. CORNER-PIECE FOR BEDSTEADS. FREDERICK EAGON, Chicago, Ill., assignor of one-third to Herman Holmagel, same place. Filed Apr. 5, 1897. Serial No. 630,899. (No model.)

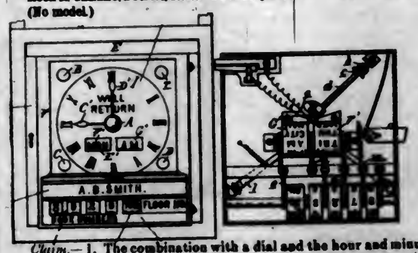
Claim.—1. In a corner-piece for bedsteads, a corner-piece formed like an angle-iron, having flanges *d*, *d'*, seat d^3, lug K', hook K, in combination with a clamp composed of two jaws having flanges G, G, curved parts D, E; part D having a flange d^4 and part E having channel d^5, into which flange d^4 of part D, fits, and interlocks and bolt connection F, the corner-piece being detachably connected to the said clamp, as set forth.

2. In a corner-piece for iron bedsteads, angle-iron L formed substantially as set forth and hook K, in combination with the sides and ends of the bedstead; and a clamp connected to the iron bed-post, the clamp being composed of the interlocking jaws D and E, bolt F, the bolt F connecting the jaws D and E, the hook K on the corner-iron engaging the bolt F, all combined and operating as set forth.

605,811. PLUCKING-MACHINE. ISIDOR DRESSNER, Brooklyn, N. Y. Filed Dec. 24, 1897. Serial No. 663,297. (No model.)

Claim.—1. The combination of a bladed roller, a belt of elastic material which is moved intermittently by the rotation of the blades of said roller, and rollers supporting the said belt and arranged to cause the said blades to bear against the belt with a gradually-increasing pressure during the time they roll in contact together, substantially as described.

2. The combination of a bladed roller, a belt of elastic material which is moved intermittently by the rotation of the blades of said roller, and rollers supporting the said belt, one of said rollers being arranged above the shaft of the bladed roller in a perpendicular line therewith, and another of said rollers being arranged in closer proximity to the blades than the latter, whereby as the blades rotate they will engage the belt and compress it gradually from the time they are in line with the first-mentioned roller until they are in line with the last-mentioned roller, substantially as described.



3. The combination of a bladed roller, an elastic belt and rollers supporting the same, said rollers comprising an inner perforated tubular oil receptacle secured by set-screws in supports and an outer sleeve fitted to rotate on the said inner tube between the sides of the supports, one of said rollers being adjustable toward or from the other rollers and provided with collars to tighten and retain the belt in position, substantially as described.

4. In combination, a bed-plate, standards erected thereon, a bladed roller mounted in said standards; an elastic belt supported by rollers and coöperating with said bladed roller; vertically-adjustable standards for carrying the belt-supporting rollers, secured in bearings formed in the bed-plate and united by a cross-bar; springs controlled by stop-nuts to press the standards upwardly; a foot-lever adapted to move the same downwardly, and a supporting-roller for the skin mounted in an arm secured to one side of a sliding carriage and open to admit skins sidewise around its free end, substantially as described.

5. In combination, a bladed roller, an elastic belt cooperating with said roller, a carriage comprising two slide-rods united by a cross-bar and working in fixed bearings; arms secured to said slide-rods and adapted to slide on stationary rods provided with adjustable stops; a spring to move the carriage in one direction, and a skin-supporting roller mounted on the free end of an arm secured to one of the said slide-rods, substantially as described.

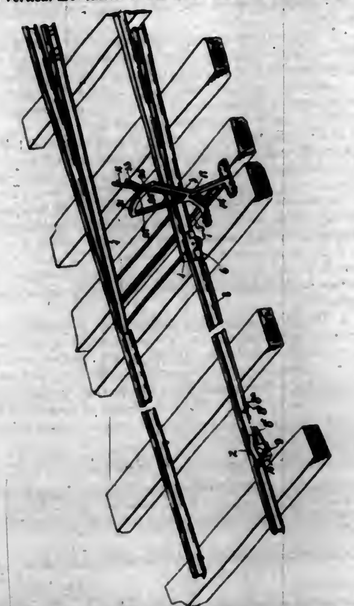
6. A bladed roller consisting of two collar portions between which extend arms to which blades are secured, said blades being formed with a concave recess along their outer edges in which are placed rods of elastic material inclosed by a flexible cover, substantially as described.

605,812. ILLUMINATED CLOCK-DIAL FOR INDICATORS, &c. ROCH R. GARBAU, Detroit, Mich. Filed May 26, 1897. Serial No. 638,186. (No model.)

Claim.—1. The combination with a dial and the hour and minute hands thereof, of hollow arbors carrying the hands, a hollow tube stationarily secured within said arbors, an incandescent lamp supported by said tube and an electric conductor connecting said lamp with the source of electricity, and a switch for controlling the lamp.

2. In an indicator, the combination of the frame or casing, a clock-dial provided with indicator-hands and with openings in the dial-indicator, rollers in said opening, and setting devices for said indicator-hands and rollers operated by buttons located on the face of the dial in proximity thereto, a miniature electric lamp mounted on the clock-face in the axial center of the indicator-hands and a transparent curtain supported in front of the clock-dial.

3. In an indicator, the combination with a primary indicating means, and a light therefor, of a supplemental indicator movably held in relation to the primary indicator and arranged in front thereof and of the light and adapted to be moved to expose the primary indicator, substantially as described.



4. In an indicator, the combination with a clock-dial, of indicating-hands, mechanism for imparting to said hands the proper relative movement provided with an operating device located in front of the clock-dial, an indicating-roll mounted in proximity to said dial and adapted to be seen through the latter, and means in front of the dial for setting said roller, substantially as described.

5. In an indicator, the combination with a clock-dial, and index-hands, of hollow arbors for the hands, means for rotating said arbors to impart the proper relative movements to the hands, an electric light located at the front or outer end of the arbors, and a support and conductors for the light passing through said arbors.

6. The combination with a clock-dial and the hour and minute hands thereof, of a hollow arbor carrying the minute-hand, electric conductors passing through said hollow arbor, and an incandescent lamp connected to and supported by said conductors in the center of the dial independent of the minute-hand and its arbor, substantially as described.

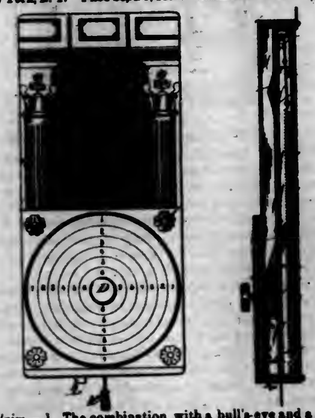
605,818. AUTOMATIC-LEVER SWITCH. JOHN F. GAYLORD, Portsmouth, Va., assignor, by mesne assignments, of one-fourth to Meyer L. Straus, Baltimore, Md. Filed Jan. 26, 1897. Renewed Mar. 3, 1898. Serial No. 673,145. (No model.)

Claim.—1. In a railway-switch, the combination with pivoted switch-rails, of a pivoted switch-lever connected to said rails and adapted to be moved vertically upon the operation of the switch, a projection mounted upon said switch-lever and adapted to lock in suitable notches on the switch-stand but be disengaged from the same upon the vertical movement of said lever, substantially as described.

2. In a railway-switch, the combination with pivoted switch-rails, of a trip mounted in proximity to one of the main rails and connected to said pivoted rails, a pivoted switch-lever connected to said movable rails and adapted to move vertically upon the operation of the switch, a switch-stand, an inclined strip mounted on said stand, a projection connected to the pivoted lever and adapted to rest on said inclined strip, and other projections mounted on the lever and adapted to engage notches in the switch-stand, substantially as described.

3. In a railway-switch, the combination with pivoted switch-rails, of a trip mounted in proximity to one of the main rails and connected to said pivoted rails, a pivoted switch-lever connected to said movable rails and adapted to be moved vertically upon the operation of the switch, and a projection mounted upon said switch-lever and adapted to lock in suitable notches on the switch-stand, but be disengaged from the same upon the vertical movement of said lever, substantially as described.

4. In a railway-switch, the combination with pivoted switch-rails, of a trip mounted in proximity to one of the main rails and connected to said switch-rails for operating the same, a pivoted vertically-movable switch-lever connected to said switch-rails, means for moving said lever vertically upon being operated, a stationary projection on said lever adapted to engage notches on the switch-stand, and a sliding pawl mounted on said lever and also adapted to engage notches upon the switch-stand to lock said lever in position, substantially as described.



5. In a railway-switch, the combination with pivoted switch-rails, of a trip mounted in proximity to one of the main rails and connected to said switch-rails for operating the same, a switch-stand, a switch-lever pivotally mounted in the same and capable of vertical movement, a rod connecting the movable switch-rails and said lever and provided with a laterally-projecting pin, a plate having an inclined slot in which said pin operates to raise and lower the lever, and a projection upon said lever adapted to engage notches formed on the switch-stand, substantially as described.

6. In a railway-switch, the combination with pivoted switch-rails, and a trip mounted in proximity to one of the main rails and connected to said pivoted rails, a switch-stand having inclined slots formed in the same, a switch-lever having trunnions mounted in said slots, means for moving said lever vertically upon being operated, and projections mounted upon said lever and adapted to lock in suitable notches formed in the switch-stand, substantially as described.

7. In a railway-switch, the combination with a switch-stand having a segmental upper surface, of a lever pivoted in said stand so as to be capable of vertical movement, and an antifriction-roller mounted on said lever and supporting the same in position by resting upon the upper segmental surface of the switch-stand, substantially as described.

8. In a railway-switch, the combination with pivoted switch-rails, of a trip mounted in proximity to one of the main rails and connected to said pivoted rails, a pivoted switch-lever connected to said movable rails and adapted to be moved vertically upon the operation of the switch, projections upon said lever adapted to engage notches formed in the switch-stand, but be lifted out of the same upon the vertical movement of said lever, and an antifriction-roller mounted on said lever and adapted to roll over the top of the switch-stand during the operation of throwing the lever, substantially as described.

605,814. TARGET. WILLIAM F. HOOMPETER, Jersey City, N. J., assignor to Frederick Meneenhauer, same place, and Oscar Schmidt, New York, N. Y. Filed Sept. 9, 1897. Serial No. 651,013. (No model.)

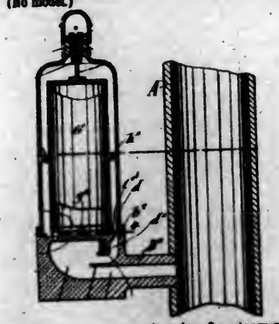
Claim.—1. The combination, with a bull's-eye and a spring-plate fixed at one end, said bull's-eye being mounted between the ends of the spring, of a movable curtain or shield, means for connecting the free end of the spring with the curtain or shield, and means for actuating said curtain or shield when the connection between the bull's-eye and the curtain is broken, substantially as set forth.

2. The combination, with a movable bull's-eye and a spring-plate fixed at one end and provided with a projecting nose or catch, said bull's-eye being fixed to the spring between the ends thereof, of a movable body provided with a pin, adapted to be engaged by said catch, and means for operating said movable body when the pin is released from said catch, substantially as set forth.

3. The combination, with a movable bull's-eye and a spring-plate carrying the same and provided with a nose or catch bent up from its free end, of a movable body or curtain provided with a projection adapted to be engaged by said nose or catch, and means for actuating the curtain when the nose or catch is disengaged from said projection, substantially as set forth.

4. The combination with a movable bull's-eye, and a spring for actuating the same, of a curtain, means for detachably connecting the curtain and the spring, a winding-up roller for the curtain, and means for operating said roller, substantially as set forth.

5. The combination with a movable bull's-eye, of a spring for actuating said bull's-eye, and means for changing the tension of said spring, substantially as set forth.



6. The combination with a movable bull's-eye, of a spring for actuating the same, and a second spring adapted to move into and out of engagement with the bull's-eye spring, substantially as set forth.

7. The combination with a box or case, having a front opening and an object behind said opening, a face plate adjacent to the opening, and a bull's-eye, the stem of which is guided in an opening in the face plate, of a movable curtain or shield adapted to cover said opening, means for connecting the bull's-eye with the curtain or shield, and means connected with the curtain or shield for actuating the same and uncovering the opening when the connection between the bull's-eye and the curtain is broken, substantially as set forth.

8. The combination with a box or case, provided with a front opening, a face plate adjacent to said front opening, a movable bull's-eye guided in the opening in the front plate, and an actuating-spring for said bull's-eye, said spring being provided with a nose or catch, of a movable curtain or shield arranged to cover said opening and

adapted to be engaged by said nose or catch, and means for raising said curtain when the nose or catch is disengaged from the same, substantially as set forth.

605,315. AUTOMATIC AIR-VALVE FOR STEAM-RADIATORS. LEONARD G. KIRK, New York, N. Y. Filed Jan. 15, 1898. Serial No. 666,782. (No model.)

Claim.—1. In an automatic air-valve for steam-radiators, the combination with a base-piece provided with suitable passages, a deflector at the upper part of the base-piece, an opening at one side of the deflector, an auxiliary deflector in said passages arranged below said opening, and a casing mounted on the base-piece above the deflector and provided at its upper end with an air-duct, of a float arranged within the casing above the said deflector, to one side of said opening and provided with a needle-valve at its upper end adapted to close said air-duct, substantially as set forth.

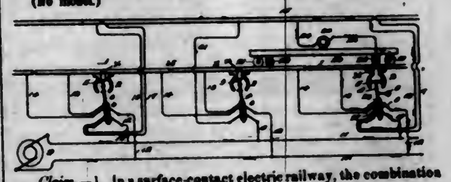
2. In an automatic air-valve for steam-radiators, the combination with a base-piece, provided with suitable passages, a deflector arranged in a horizontal plane at the upper part of the base-piece, said deflector having an opening at one side and provided adjacent to said opening with an upwardly-projecting lip, and a casing supported on said base-piece above said deflector and provided at its upper end with an air-duct, of a float arranged within the casing above said deflector and to one side of said lip and being provided with a needle-valve adapted to close said air-duct, substantially as set forth.

3. In an automatic air-valve for steam-radiators, the combination with a base-piece, provided with passages through the same, a casing arranged on the base-piece, and provided with an air-duct at its upper end, and baffle-plates projecting inwardly from the inner surface of said casing, of a float arranged in said casing and guided by said baffle-plates in its up-and-down motion, said float being provided with a needle-valve adapted to close said air-duct, substantially as set forth.

605,316. WHEELBARROW. RENUS A. KNEELAND, Benton Harbor, Mich. Filed Apr. 3, 1896. Serial No. 586,004. (No model.)

Claim.—1. The combination with a wheelbarrow: of an auxiliary wheel B; a frame composed of side pieces C, secured to the axle of said wheel; and having notches at their upper ends; cross-bar H, between the side pieces C, above the said wheel B; arms D, D, pivoted to the axle at each side of the wheel extending upwardly and forwardly and pivotally connected to the handles of the wheelbarrow; loop-guides G, G, on the handles of the wheelbarrow for receiving the side pieces C, C, and engaging the ratchet-notches thereon; levers E, E, pivoted to the handles of the wheelbarrow positioned to act upon the side pieces C, C, and throw them out of engagement with the guides G, all coacting together substantially as described for the purpose specified.

2. The combination with a wheelbarrow: of an auxiliary wheel B; a frame composed of side pieces C, secured to the axle of said wheel; and having notches in their upper ends; arms D, D, pivoted to the axle at each side of the wheel extending upwardly and forwardly and pivotally connected to the handles of the wheelbarrow; loop-guides G, G, on the handles of the wheelbarrow for receiving the side pieces C, C, and engaging the ratchet-notches therein; levers E, E, pivoted to the handles of the wheelbarrow positioned to act upon the side pieces C, C, and throw them out of engagement with the guides G, all coacting together substantially as described for the purpose specified.



3. The combination in a wheelbarrow of an auxiliary rear wheel; bars D, D, pivoted to said wheelbarrow and extending downwardly and rearwardly and connecting to the said auxiliary wheel and arms C, C, extending upwardly said wheel; and suitable means of adjustably connecting the same to the handle of the wheelbarrow to adjust the same to any height desired as specified.

4. The combination of a wheelbarrow of an auxiliary wheel downwardly and rearwardly extending bars pivotally connecting said wheel and wheelbarrow together; loop-guides on the handle of said wheelbarrow; upwardly-extending bars from said wheel having ratchet-notches to engage the loop-notches on the handles; and levers E, pivoted to the handles to throw said ratchet bars out of engagement for the purpose specified.

5. In an attachment for a wheelbarrow, a wheel B, with side pieces D, D and C, C, pivotally secured to the axle thereof; and suitable means of securing the opposite ends of said sides to the barrow as specified.

6. The combination of a wheelbarrow; an auxiliary wheel to the rear of said wheelbarrow; a frame for carrying said rear wheel freely movable vertically in relation to the handles of said wheelbarrow, a suitable ratchet connection for securing said rear wheel automatically to the handles of the wheelbarrow to control the height of the handles as they are raised, and means of releasing the ratchet connection to permit the handles to be lowered with relation to the rear wheel for the purpose specified.

605,317. ELECTRIC-RAILWAY SYSTEM. WILLIAM LAWRENCE, New York, N. Y., assignor to the Universal Surface Electric Railway Company, of West Virginia. Filed Dec. 1, 1897. Serial No. 660,348. (No model.)

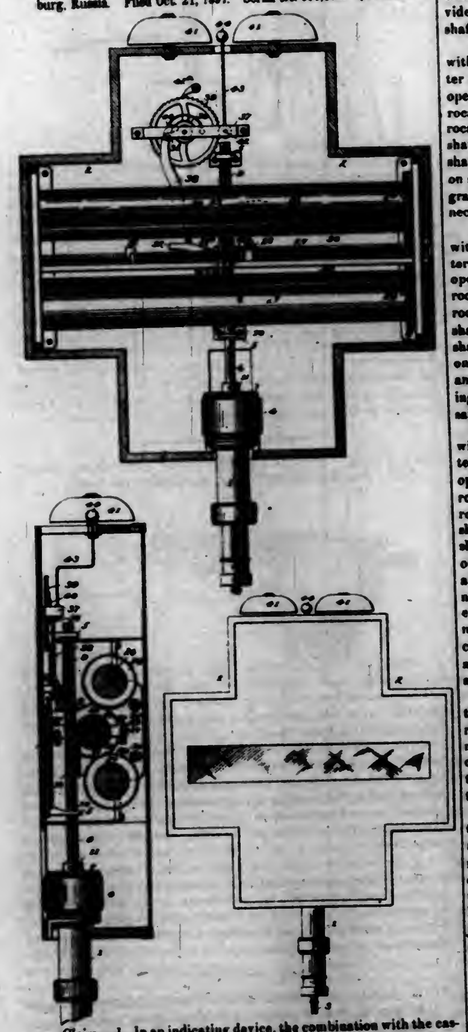
Claim.—1. In a surface-contact electric railway, the combination of a moving vehicle, field-magnet poles located between the tracks at suitable intervals, an armature mounted for movement between the faces of each pair of poles, and a magnet carried by the moving vehicle supplying a magnetic flux to the field-poles for moving the armature.

2. The combination of feeder-rail sections, pole-pieces upon each of said sections, an armature pivoted at its center and disposed between the adjacent ends of said pole-pieces normally at right angles to said sections, wire connections, and a source of energy, whereby the armature is caused to swing into line with said sections and find its relative poles.

3 The combination of feeder-rail sections, pole-pieces upon said sections, an armature hung between said pole-pieces, and means for energizing said sections, whereby the armature is caused to swing into line with said sections.

4. The combination of a sectional track-rail, feeder-rail sections, pole-pieces upon said sections, an armature pivotally hung between said pole-pieces, an oscillating shaft upon which the armature is hung, means for normally holding the armature at right angles to said sections, switch-pieces upon said shaft and oscillating therewith, fixed switch-pieces, wires leading from the switch-pieces to adjacent sectional track-rails, a source of electrical energy, and wires leading therefrom to the oscillating switch-pieces upon the armature-shaft.

5. The combination of feeder-rail sections, pole-pieces upon said sections, a centrally-pivoted armature hung between said poles, an oscillating shaft upon which the armature is hung, a switch-piece upon the shaft, wire connections, a source of energy for energizing the feeder-rail sections and causing the armature to find its relative poles and actuate the switch, and a car carrying a motor and a current-collector.



6. In an electric-railway system the combination of a junction-box having a top provided with a cover and a seat for the feeder-section, an oscillating shaft mounted therein carrying an armature and a switch, and a secondary box within the junction-box inclosing the switch.

7. In an electric-railway system, a junction-box having a seat for a feeder-rail extending longitudinally across one side of the same, a secondary box within the junction-box inclosing a switch mechanism, and a removable cover for the junction-box.

8. A junction-box for surface-contact railways provided with a seat at one side for the surface contact, a cover-plate alongside thereof, and having a removable secondary switch-box within the junction-box, a shaft within the secondary switch-box carrying a switch, and extending out across the junction-box and carrying an armature.

9. A junction-box for surface-contact railways provided with a seat at one side for the surface contact, a cover-plate alongside thereof, a secondary switch-box within the junction box having a removable cover lying under the removable cover of the junction-box; a shaft extending across the junction-box and through the secondary box, having a switch within the secondary box, and an armature within the junction-box.

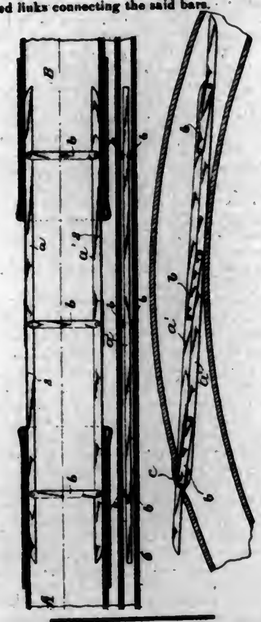
605,318. STATION-INDICATOR. OSSEME LEDOWSKY, St. Petersburg, Russia. Filed Oct. 21, 1897. Serial No. 656,112. (No model.)

Claim.—1. In an indicating device, the combination with the casing and with a revoluble roll or rolls journaled therein and carrying the matter of indication, of a revoluble horizontal shaft journaled in said casing and operatively connected with said roll or rolls, a longitudinally-reciprocatory vertical rack-carrying rod also mounted in said casing means for operating said reciprocatory rod, a pinion loosely mounted on said shaft and engaging the rack on said rod, a pair of reversely-disposed laterally-movable ratchet-wheels arranged one on each side of said pinion and keyed on the shaft, pawls carried by said pinion and adapted to alternately engage said ratchet-wheels, and automatic means for throwing said pawls into engagement with said ratchet-wheels, substantially as described.

2. In an indicating device, the combination with the casing and with a revoluble roll or rolls journaled therein and carrying the matter of indication, of a revoluble horizontal screw-threaded shaft journaled in said casing, intermeshing gears mounted on said rolls and the shaft, a longitudinally-reciprocatory vertical rack-carrying rod also mounted in said casing, means for operating said reciprocatory rod, a pinion engaging the rack of said shaft, a pawl carried on each face of said pinion, a laterally-movable sleeve keyed on the shaft, constituting the journal for said pinion and provided at its ends with reversely-disposed ratchet-wheels, and a pair of adjustably-connected brackets mounted on said shaft, the one loosely and the other provided with internal screw-threading engaging the threading of said shaft, substantially as described.

3. In an indicating device, the combination with the casing and with a revoluble roll or rolls journaled therein and carrying the matter of indication, of a revoluble shaft journaled in said casing and operatively connected with said roll or rolls, a longitudinally-reciprocatory rod mounted in said casing, means for operating said reciprocatory rod, means for transmitting motion from said rod to said shaft, automatic means for reversing the direction of rotation of said shaft, an arm carried by said reciprocatory rod, a pair of bells mounted on said casing, a hammer for said bells trunnioned in said casing and gravity-actuated means for operating said hammer operatively connected with said arm, substantially as described.

4. In an indicating device, the combination with the casing and with a revoluble roll or rolls journaled therein and carrying the matter of indication, of a revoluble shaft journaled in said casing and operatively connected with said roll or rolls, a longitudinally-reciprocatory rod mounted in said casing, means for operating said reciprocatory rod, means for transmitting motion from said rod to said shaft, automatic means for reversing the direction of rotation of said shaft, an arm carried by said reciprocatory rod, a pair of bells mounted on said casing, a vertical elastic hammer trunnioned in said casing and situated between the bells, a toothed wheel journaled in the casing and engaging said hammer and operative connection between said toothed wheel and the arm, substantially as described.



5. In an indicating device, the combination with the casing and with a revoluble roll or rolls journaled therein and carrying the matter of indication, of a revoluble shaft journaled in said casing and operatively connected with said roll or rolls, a longitudinally-reciprocatory rod mounted in said casing, means for operating said reciprocatory rod, means for transmitting motion from said rod to said shaft, automatic means for reversing the direction of rotation of said shaft, an arm carried by said reciprocatory rod, a pair of bells mounted on said casing, a vertical elastic hammer trunnioned in said casing and situated between the bells, a toothed block mounted on the trunnion for said hammer, a toothed wheel journaled in the casing and engaging the toothed block of said hammer, a ratchet-wheel journaled concentrically with said toothed wheel, a spring actuated pawl carried by said toothed wheel and engaging the ratchet-wheel, and a system of gravity-actuated levers connected to said ratchet-wheel and adapted to be engaged by said arm, substantially as described.

6. In an alarm mechanism for an indicating device, the combination with the case for said device and with a vertically-reciprocatory rod mounted therein, of an arm carried by said rod, a pair of bells mounted on said casing, a vertical elastic hammer trunnioned in said casing and situated between the bells, a toothed wheel journaled in the casing and engaging said hammer and operative connection between said toothed wheel and the arm, substantially as described.

7. In an alarm mechanism for an indicating device the combination with the case for said device and with a vertically-reciprocatory rod mounted therein, of an arm carried by said rod, a pair of bells mounted on said casing, a vertical elastic hammer trunnioned in said casing and situated between the bells, a toothed block mounted on the trunnion for said hammer, a toothed wheel journaled in the casing and engaging the toothed block of said hammer, a ratchet-wheel journaled concentrically with said toothed wheel, a spring-actuated pawl carried by said toothed wheel and engaging the ratchet-wheel, and a system of gravity-actuated levers connected to said ratchet-wheel and adapted to be engaged by said arm, substantially as described.

605,319. APPARATUS FOR SECURING ENDS OF BICYCLE-TIRES. RICHARD A. LEIGH, Boston, Mass., assignor, by mesne assignments, to the Consolidated Rubber Works, same place. Filed Oct. 4, 1897. Serial No. 653,981. (No model.)

Claim.—As a means for holding the separated ends of a tire in the process of construction, a collapsible holder comprising parallel bars and pivoted links connecting the said bars.

605,820. COMPOSITION FOR REMOVING BOILER INCRUSTATIONS. GEORGE LINDE, Omaha, Nebr. Filed Jan. 6, 1898. Serial No. 666,096. (No specimens.)

Claim.—The herein-described compound, consisting of gallic powder, sal-ammoniac, soda, salt, acetic acid, catechu, and Irish moss, in about the proportions stated.

605,821. OILER. JOHN LEES, Waterbury, Conn., assignor to The Scovill Manufacturing Company, same place. Filed July 24, 1897. Serial No. 645,755. (No model.)

Claim.—1. An oiler, comprising a liquid-receptacle, a detachable closer therefor, a longitudinally-shifting spout guided by said closer, a pin within said liquid-receptacle projecting into said spout, and extending to a point above the limit of outer movement of the lower end of the spout, and a recess in the side of said pin toward its upper end, the spout and pin forming an oil-tight joint when the spout is pushed inwardly beyond said recess said pin assisting in holding the spout in the latter's outermost position.

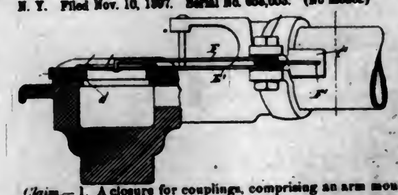
2. An oiler, comprising a liquid-receptacle, an extensible spout therefor guided in a detachable closure at one end of said liquid-receptacle, a stuffing-box at the inner end of said spout, a stationary pin within said liquid-receptacle projecting through said stuffing-box and into the spout, the length of said pin being sufficient to project beyond the limit of outer movement of said stuffing-box, and a recess in the side of said pin whereby the liquid may be ejected from said receptacle through said spout when the latter is moved to its outer limit.

3. In an oiler having a longitudinal extensible spout, a curved nozzle end, a stop to limit the inward movement of said spout, comprising a pin held within said receptacle, projecting up into said spout and engaging the bent end of the spout when the same is moved to its inward position.

4. In combination, an oil receptacle, an extensible nozzle, a pin in said receptacle having a reduced upper end and entering said nozzle when in its extended position, said reduced upper end engaging and holding said nozzle in said nozzle's extended position but allowing oil to then pass by said reduced portion.

5. In an oiler, in combination, a receptacle for oil, an extensible nozzle, a pin in said receptacle having part of its periphery at its upper end cut away, and extending into said nozzle at all times, said nozzle closely fitting the periphery of said pin at all times and aiding in retaining said nozzle in its extended position, but allowing oil to pass at the point where said periphery is cut away.

6. In an oiler, in combination, an oil-receptacle, an extensible hollow nozzle, a pin in said receptacle extending into said nozzle and closely fitted as to its periphery by said nozzle, said nozzle, in its extended position, fitting said pin and partially held in this position thereby but uncovering a passage in said pin for oil to flow from said receptacle.

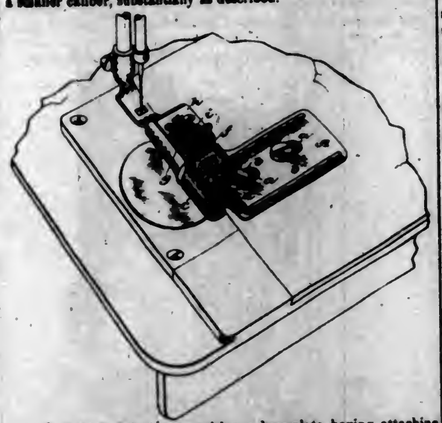


605,822. GRAIN-DRILL. JOHN F. MONTGOMERY and WILLIAM T. BERRY, Cocsawattee, Ga. Filed Mar. 14, 1898. Serial No. 673,819. (No model.)

Claim.—1. A grain-drill having, in combination, a standard, a furrow-forming shoe carried thereby, and a pair of fender strips or blades secured at their front ends to the heel end of the standard and having their rear ends flared outwardly and upwardly on a gradually-increasing curve from the lower to the upper edges thereof, substantially as described.

2. A grain-drill having, in combination, a standard, a furrow-forming shoe carried thereby, a lug on the heel end of the standard formed with parallel sides and a transverse bolt-hole, vertical fender-carrying strips arranged on the opposite sides of the lug and formed with longitudinal slots, a bolt passing through said slots and transverse hole in the lug and securing the strips to said lug, and a pair of fender-plates secured at their front ends to said strips and extending rearwardly therefrom, said plates being flared outwardly and upwardly at their rear ends on a gradually-increasing curve from the lower to the upper edges thereof, substantially as described.

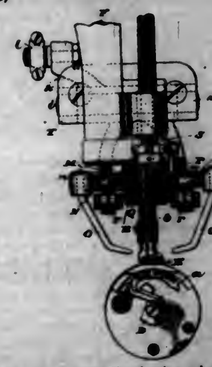
605,823. CLOSURE FOR COUPLINGS. JOSEPH MUHR, Dunkirk, N. Y. Filed Nov. 10, 1897. Serial No. 658,053. (No model.)



Claim.—1. A closure for couplings, comprising an arm mounted to swing, and formed with a cap, a spring for pressing against the said cap, and an upwardly-turned flange on the said cap, for moving the latter out of engagement with the face of the coupling, substantially as shown and described.

2. A closure for hose-couplings, the closure comprising a cap mounted to swing edgewise toward and from the coupling member to command the mouth thereof, the cap having a downwardly-projecting flange engaging the coupling member to limit the movement of the cap and the cap also having an upwardly-projecting flange adapted to be engaged by the companion coupling member to push the cap out of place.

3. A closure for couplings, the closure comprising a cap mounted to swing edgewise toward and from the coupling members to command the mouth thereof, the cap having an upwardly-projecting flange capable of being engaged by one of the coupling members as the two members are moved to connection, whereby the cap is moved edgewise out of active position.



605,824. FOLDING-GUIDE FOR SEWING-MACHINES. LORENZ MUTHER, Oak Park, Ill., assignor to The Union Special Sewing Machine Company, Chicago, Ill. Filed Feb. 10, 1898. Serial No. 670,726. (No model.)

Claim.—1. A folding device comprising a base-plate having attaching means and carrying a folding-guide, and a supplemental guide hinged to the main guide and having its guiding-channel when in operative position in longitudinal alinement with the guiding-channel of the main guide and being of the same character as the latter, but of a smaller caliber, substantially as described.

2. A folding device comprising a base-plate having attaching means and carrying a folding-guide, a plate removably secured to said folding-guide, a supplemental guide hinged to said plate and having its guiding-channel when in operative position in longitudinal alinement with the guiding-channel of the main folding-guide, substantially as described.

605,825. SEWING-MACHINE. LORENZ MUTHER, Oak Park, and ELIAS C. HOLLAND, Austin, Ill., assignors to The Union Special Sewing Machine Company, Chicago, Ill. Filed Feb. 28, 1898. Serial No. 672,009. (No model.)

Claim.—1. A sewing-machine having a bed-plate, a feeding device working longitudinally thereof, stitch-forming mechanism including a looper-shaft arranged longitudinally of the bed-plate and having a reciprocating and oscillating movement therein, a looper on said shaft, a plurality of vertically-arranged needles, and a set of thread or cord guiding devices, reciprocating back and forth across the longitudinal axis of the bed-plate and depositing threads or cords in position to be secured to the fabric by the rows of stitching, substantially as described.

2. A sewing-machine having a bed-plate, a feeding device working longitudinally thereof, stitch-forming mechanism which includes a looper-shaft having a reciprocating and oscillating movement in the bed-plate, a vertically-arranged needle, a rocking shaft arranged transversely of the bed-plate and above the same and a set of thread-carrying devices operatively connected with the rocking shaft and adapted to reciprocate across the longitudinal axis of the bed-plate, with means for rocking said shaft, substantially as described.

3. A sewing-machine comprising a main shaft, a gear-wheel thereon, a gear-wheel in mesh therewith arranged on an axis parallel with the axis of the main shaft, a rocking crank-frame with its axis also parallel with the axis of the main shaft, universal-joint connections between the second gear-wheel and the rocking crank-frame, thread-carrying fingers, a connecting-rod between the fingers and the rocking crank-frame universally jointed at each end respectively to said frame and fingers; substantially as described.

4. A sewing-machine having a suitable head, a lug thereon, a sleeve secured in said lug, angle-arms with thread-carrying fingers secured at their outer ends and provided with collars embracing the sleeve and journaled thereon, and means for oscillating said angle-arms, substantially as described.

5. A sewing-machine having a suitable head, a lug thereon, a sleeve secured on said lug and having a head on its lower end, angle-arms with thread-carrying fingers secured at their outer ends and provided with collars embracing the sleeve and journaled thereon between the lug and the head, and means for oscillating said angle-arms, substantially as described.

6. A sewing-machine having a driving shaft a suitable head, a lug thereon, a sleeve secured in said lug, angle-arms with thread-carrying fingers secured at their outer ends and provided with collars embracing the sleeve and journaled thereon, said angle-arms being provided with downwardly-extending ball-studs, connecting-rods secured thereto, a rocking crank-frame arranged to swing on an axis transverse to the axis of the machine-frame and having ball-stud connections with the said connecting-rods, and connections between the rocking crank-frame and the driving shaft; substantially as described.

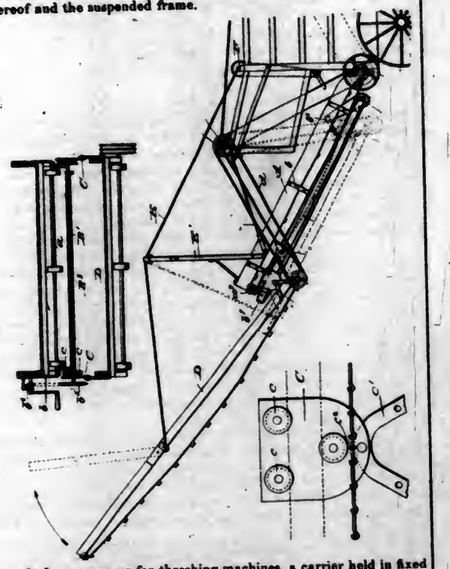
7. A sewing-machine comprising a driving shaft, a suitable stitch-forming mechanism and an overhanging frame or gooseneck, a bracket secured upon said frame or gooseneck, said bracket having downwardly-extending lugs, a pin or rod *i* secured to said lugs, a crank-frame sleeved on said pin or rod and having downwardly-extending arms *n* and an upwardly-extending lug or arm *k*, a connecting-rod attached to the arm *k* and connections between said connecting-rod and the driving-shaft for oscillating the crank-frame, connection-rods, as *q*, operatively connected with the downwardly-extending arms *n* and thread-carrying finger-supporting levers secured to said connection-rods *q*, substantially as described.

8. A sewing-machine having a bed plate, a feeding device working longitudinally thereof, a looper-shaft arranged longitudinally of the bed-plate and having a reciprocating and oscillating movement therein, a looper on said shaft, and complemental stitch-forming mechanism which includes a device reciprocating back and forth across the longitudinal axis of the bed-plate to make a cross-stitch; substantially as described.

605,826. TROLLEY CONNECTION FOR ELECTRIC CARS. JOHN G. MCLAUGHLIN, Brooklyn, N. Y., assignor of one-half to Robert W. Gleason, same place. Filed Dec. 28, 1897. Serial No. 663,916. (No model.)

Claim.—1. The combination of the trolley-pole P, the swinging frame 3 having cheeks 3^a extending upward above and beyond the extremity of the trolley-pole, and the wheel 6 mounted between the upwardly-projecting cheeks 3^a of the swinging frame as set forth.

2. The combination of the trolley-pole P, the swinging frame 3 pivoted to the trolley-pole near its extremity, the sliding frame 4 guided by the frame 3; and the trolley-wheel 6, mounted in the upwardly-projecting cheeks 4^a of the sliding frame, by an axis 5, at a point above the pivot 2 by which the swinging frame is connected to the pole substantially as set forth.



3. The combination of the trolley-pole P with the pivoted frame 3, sliding frame 4, trolley 6 running therein, the spring 7 and the trolley-rope 8, connected to the sliding frame 4, substantially as described.

605,827. FOLDABLE STRAW-CARRIER FOR THRESHING-MACHINES. ALBERT R. MCMULLEN, Lemmon, S. D. Filed Dec. 22, 1897. Serial No. 663,015. (No model.)

Claim.—1. In a conveyer for threshing-machines, the combination of a carrier attached to and supported from the threshing-machine, a frame suspended beneath said carrier, a pair of slides mounted on the suspended frame, a second carrier pivotally attached to the slides, an end section hinged to the second carrier and adapted when folded to lie over the same so that it may be housed beneath the suspended frame, substantially as shown.

2. In a conveyer for threshing-machines, a carrier held in fixed engagement with the threshing-machine, a frame suspended beneath

said fixed carrier and provided with side bars, slides having rollers for engagement with the side bars, means for moving the slides upon the side bars of the suspended frame, in combination with an adjustable carrier of greater length than the fixed carrier, the adjustable carrier being pivotally attached to the slide and provided with an end section which is hinged thereto so as to be folded upon the lower section and when so folded to be housed between the lower section thereof and the suspended frame.

3. In a conveyer for threshing-machines, a carrier held in fixed engagement with the threshing-machine, a frame suspended from said carrier, slides mounted on the side bars of the suspended frame, a second carrier pivotally attached to the slides, chains attached to the slides, a shaft with sprocket-wheels over which the chains pass, a spring attached to the shaft so as to be coiled thereon when the slides are moved toward the same and means for manually rotating the shaft, substantially as shown and for the purpose set forth.

4. In combination with a carrier-section, a frame suspended therefrom, slides mounted on said frame, a second carrier-section pivoted to the slides, of means for moving the slides on the suspended frame comprising endless chains which are connected to the slides, a shaft having sprocket-wheels over which the chains pass, means for turning the shaft and a spring attached to the shaft so as to exert a tension thereon and retard its rotation when the slides are moved toward said shaft, substantially as set forth.

5. In a straw-conveyer for threshing-machines, the combination with a fixed section, its conveyer-belt, a frame suspended from the fixed section, slides mounted on the suspended frame, chains attached to the slides, a shaft having sprocket-wheels with which the chains engage, a second carrier-section pivotally attached to the slides, a drive pulley for the conveyer-belt of the second section, a belt which passes over said pulley and a driven pulley on the threshing-machine, said belt being looped as shown, a pulley which engages with the loop of the belt and a flexible connection attached to said pulley, substantially as shown and for the purpose set forth.

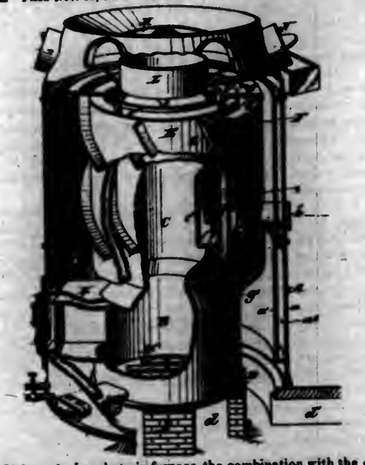
6. In a straw-conveyer for threshing-machines, the combination with a fixed carrier, of a frame attached thereto, slides mounted on the frame, means for moving the slides, a pair of standards with rollers carried by the fixed carrier, an extensible conveyer-section the lower end of which is held in pivotal engagement with the slides, a flexible connection attached to the extensible conveyer, a drum mounted on the threshing-machine with which the flexible connection engages, a looped driving-belt between the threshing-machine and the extensible carrier, a pulley mounted on the looped portion of said belt and a flexible connection attached to the pulley, substantially as shown and for the purpose set forth.

605,328. PAPER-FEEDING MACHINE. JOHN F. MCNUTT, Warren, Ohio, assignor to the Harris Automatic Press Company, Niles, Ohio. Filed July 3, 1897. Serial No. 643,272. (No model.)

Claim.—1. A feeder comprising a longitudinally-movable rod, a head mounted on said rod so as to move axially thereon, and having an upper, forward edge forming a shoulder, means for adjusting said head perpendicularly to said rod and a block on the forward end of said head having its inner edge adjacent to said shoulder and tapered on its upper surface toward its outer edge, and means for adjusting said block relatively to said shoulder, substantially as set forth.

2. A feeder comprising a longitudinally-movable rod, a head mounted on said rod so as to move axially thereon and having an upper forward edge forming a shoulder, a block on the forward end of said head extended in advance of said shoulder and having its upper surface tapered, a spring interposed between said head and block exerting an upward pressure on the latter, and means for adjusting said block at its sides, substantially as set forth.

3. A feeder comprising a longitudinally-movable rod, a head mounted on said rod so as to move axially thereon and having a forward edge, means for adjusting said head perpendicularly to said rod, a block on the forward end of said head extended in advance thereof and having its upper surface inclined, and means engaging the sides of said block for adjusting and holding the same relative to the forward edge of said head, substantially as set forth.

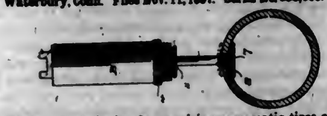


4. A feeder comprising a longitudinally-movable rod, a sleeve loose on said rod so as to move axially thereon, a head from which said sleeve extends having an upper forward edge forming a shoulder, a block on said head having an upper inclined surface, said block being extended in advance of said head, a spring interposed between said head and block exerting an upward pressure on the latter, and screws carried by said block at its sides for adjusting said block bodily or at either side, as set forth.

5. A feeder comprising a longitudinally-movable rod, a sleeve loose on said rod and having a bifurcated end a head adjustably held to said bifurcated end and having a forward edge forming a shoulder, and a block on said head capable of being raised and lowered thereon, substantially as and for the purpose stated.

6. The combination with the rod, of the head mounted on said rod having forward grooved ends and an upper forward edge forming a shoulder, a block having its upper surface inclined and formed with a longitudinal recess to accommodate said head, a spring between said head and block bearing upwardly on the latter, and screws carried by said block at its sides and engaging said head, whereby the block may be adjusted bodily or at either side, substantially as set forth.

7. The combination with the rod, of a sleeve swiveled thereon having a bifurcated end, a head having a lip, and a screw adjustably holding said lip within said bifurcated end, a block fitted on said head so as to be moved up and down thereon, said block having its upper surface inclined, a spring fitting in a recess of said block and bearing at one end against a shoulder of said head, and screws carried by said block and engaging said head for adjusting the former, substantially as set forth.



605,329. HOT-AIR FURNACE, &c. THOMAS G. NEAL, Warren, Pa. Filed Nov. 11, 1897. Serial No. 658,166. (No model.)

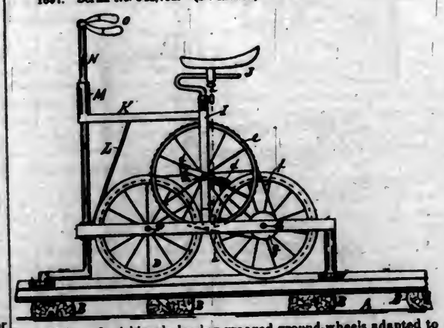
Claim.—1. In a hot-air furnace, the combination with the outer casing and inner heating drum, of a plurality of vertically-disposed radiators encircling said drum and each other, a plurality of deflectors circuitously arranged between said radiators, outlets connecting, respectively, the heating-drum with the adjacent radiators and the radiators with each other and an outlet connecting the outermost radiator with the chimney; said outlets being located in the lower portions of said radiators whereby to provide an indirect circulation of the products of combustion, substantially as described.

2. In a hot-air furnace, the combination with the outer casing and inner heating-drum, of a plurality of vertically-disposed radiators encircling said drum and each other, a plurality of deflectors circuitously arranged between said radiators, outlets connecting, respectively, the heating-drum with the adjacent radiator and the radiators with each other and an outlet connecting the outermost radiator with the chimney, said outlets being located in the lower portions of said radiators, and vertical partitions in each radiator located between the inlet and outlet openings thereof, substantially as described.

605,330. DEVICE FOR REPAIRING PNEUMATIC TIRES. PHILO NEWELL, Oakville, Conn., assignor of one-half to Frederick J. Wooster, Waterbury, Conn. Filed Nov. 11, 1897. Serial No. 658,165. (No model.)

Claim.—1. A device for repairing pneumatic tires comprising a hub threaded at each end and having at one end a stem threaded at its outer end, and a shell adapted to engage the other end of the hub and to serve as a magazine, substantially as shown, for the purpose specified.

2. A device for repairing pneumatic tires comprising a hub threaded at each end and having at one end a stem threaded at its outer end, a shell adapted to engage the hub and inclose the stem, and a shell adapted to engage the other end of the hub and to serve as a magazine, substantially as shown, for the purpose specified.

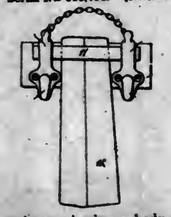


3. A device for repairing pneumatic tires comprising a hub having a circular rib and threaded at each end and having at one end a stem threaded at its outer end, a shell adapted to engage the hub and inclose the stem and having at its outer end a cutter and a shell adapted to engage the other end of the hub and to serve as a magazine substantially as shown, for the purpose specified.

4. A device for repairing pneumatic tires comprising a hub threaded at each end and having at one end a stem threaded to engage the shank of the plug, a shell adapted to engage the hub and inclose the stem and a shell adapted to engage the other end of the hub and to serve as a magazine for plugs and having at its outer end prongs adapted to engage the outer head of the plug.

5. The plug C comprising an inner head having a shank formed integral therewith and threaded internally and externally and an outer head threaded to engage the external thread upon the shank.

6. A device for repairing pneumatic tires comprising a hub threaded at each end and having at one end a threaded stem, a shell adapted to engage the other end of the hub and serve as a magazine for plugs and having at its outer end prongs and a plug consisting of an inner head and a shank internally threaded to engage the stem and externally threaded to engage an outer head which is itself adapted to be engaged by the prongs.

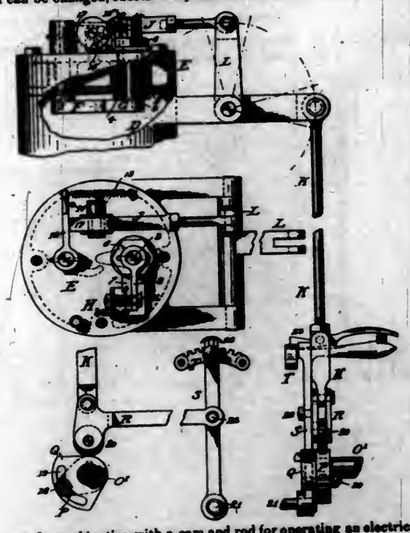


605,331. BICYCLE. CARL F. NILSON, Gile, Wis. Filed June 21, 1897. Serial No. 641,732. (No model.)

Claim.—1. A bicycle having grooved ground-wheels adapted to ride on a rail, a frame supported by said wheels and having horizontal motion to either side, guiding-rollers mounted on horizontally-swinging arms and touching the sides of the rail, said arms being operatively connected with a pair of handles within easy reach of the rider, substantially as and for the purpose set forth.

2. In a bicycle, the combination of a suitable frame, a pair of grooved ground-wheels carrying same, and being adapted to run on a rail and having lateral motion in direction of their shafts, a crank-shaft mounted in the frame and geared to one of the ground-wheels, a seat for the rider, mounted on said frame, a pair of handles for the rider to have hold of and horizontally-swinging arms operated by said handles and carrying guide rollers adapted to touch the sides of the rail and throw the frame from side to side, substantially as and for the purpose set forth.

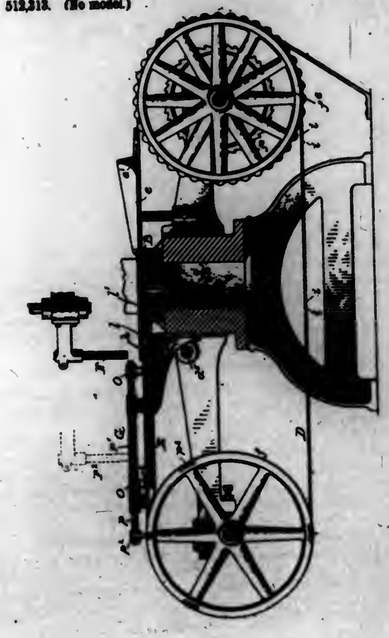
605,332. GARMENT-HANGER. THOMAS G OWEN, Newport, R. I. Filed Dec. 4, 1897. Serial No. 660,751. (No model.)



Claim.—A garment-hanger having a body and a bracket fixed thereto and provided with a forwardly projecting hook and the bracket also having a forwardly and upwardly projecting hook both hooks being adapted to carry garments and the forwardly and upwardly projecting hook being provided with a wall inclined toward the body, so that a cleat may be forced between the body and said wall.

605,333. IGNITER FOR EXPLOSIVE-ENGINES. OSCAR OWEN, San Francisco, Cal., assignor to the American Type Founders Company. Filed Nov. 27, 1896. Serial No. 613,671. (No model.)

Claim.—1. In an igniter for explosive-engines, the combination with two pivotal terminal electrodes having returning-springs, and operating arms or levers, of a reversible push-bar, having cam curves on opposite edges placed out of line with each other, a guide-roller for said push-bar, and connections from the engine-shaft for operating said push-bar, substantially as described.

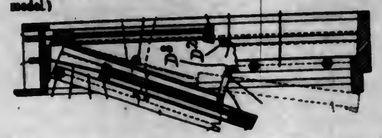


2. In an igniter for explosive-engines, and in combination, movable igniting-electrodes, a rod for operating said electrodes, a cam mounted on a geared-down shaft, for operating said rod, and means for adjusting the end of said rod relatively to the cam, in order to vary the time of its operation by the cam, substantially as described.

3. In an explosive-engine having an electrical igniter, a shaft geared down from the engine-shaft, a cam mounted on said shaft, a rod connected to the igniter, an adjustable lever, means for locking said lever in different adjustments, and a connection from said lever to the said rod, adapted, by the adjustment of said lever, to be placed in different positions relatively to the cam, whereby the time of ignition can be changed, substantially as described.

4. In combination with a cam and rod for operating an electrical igniter, a lever connected to said rod, a latch carried by said lever, and a toothed sector for locking said latch and lever, substantially as described.

605,884. SHEET-FEEDING MECHANISM FOR PUNCHING-MACHINES. WILLIAM PAINTER, Baltimore, Md., assignor to the Crown Cork and Seal Company, same place. Filed May 24, 1894. Serial No. 512,313. (No model.)



Claim.—1. In a sheet-feeding mechanism, the combination substantially as hereinbefore described, of a feeding belt or belts provided with upwardly-projecting feeding-studs, capable of puncturing the material to be fed, and a reciprocating socket punch or punches coöperating with said studs for forcing them through, and into controlling engagement with each sheet of the material.

2. In a sheet-feeding mechanism, the combination substantially as hereinbefore described, of a pair of parallel endless bands provided with upwardly-projecting feeding-studs; means for intermittingly moving said bands; and a pair of socket-punches reciprocated toward and from said studs, the organization being such that when said studs and punches register with each other, the studs will be forced through a sheet of material resting thereon thereby uniting the sheet at its side edges to said bands.

3. In an organization wherein sheets of material are to be intermittingly fed to tools adapted to operate thereon, the combination with intermittingly-operated sheet-feeding bands provided with puncturing studs, of coöperating socket-punches, a stationary sheet-supporting bed between said bands, a stationary end gage and side edge gages, the organization being such, that when a sheet of material has been placed upon said bed, the side gage will present gaging-contacts against one side edge of the sheet, the latter will be properly located with relation to the puncturing-studs, and enable the socket-punches to force said studs through the sheet of material at precisely accurate points for assuring a proper delivery of the sheet to the tools.

4. In an organization wherein sheets of material are to be intermittingly fed to tools adapted to operate thereon, the combination with intermittingly-operated sheet-feeding bands provided with punching-studs and of coöperative socket-punches, automatically-operated side edge gages substantially as hereinbefore described, the organization being such, that when a sheet of material has been fed to said gages previously retired from their gaging position, they will be automatically restored to the gaging position before the engagement of the socket-punches with the punching-pins.

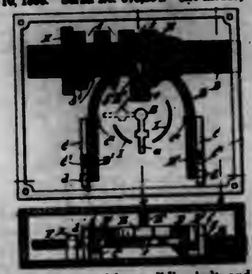
605,885. WINDOW-FRAME. FRANCIS X. PAYMENT and JOHN C. HARTIG, Chicago, Ill. Filed Nov. 9, 1896. Serial No. 611,602. (No model.)

Claim.—1. A window-frame provided with grooves at each side thereof in which fits the window-sash, the upper part of the grooves on each side being associated with a strip, said strips connected with the window-frame so that they may be moved to an angular position, an arm pivotally connected to the lower end of one of said strips, said arm adapted to engage the window-frame when the strip containing the groove is in such a position that the two parts of the groove are in line so as to lock said strip in this position, said arm adapted to be moved so as to release the strip and allow it to be moved to its angular position.

2. A window-frame provided with grooves at each side thereof in which fits the window-sash, the upper part of the grooves on each side being associated with a strip, said strips connected with the window-frame so that they may be moved to an angular position, an arm pivotally connected to the lower end of one of said strips, said arm adapted to engage the window-frame when the strip containing the groove is in such a position that the two parts of the groove are in line so as to lock said strip in this position, said arm adapted to be moved so as to release the strip, and allow it to be moved to its angular position, said arm adapted to be rotated about its pivotal point until it projects toward the window, the arm engaging the window-frame so as to hold said strip in its angular position.

3. A window-frame provided at its sides with grooves in which the window-sashes move, the upper part of each groove being associated with a strip which is pivotally connected with the window-frame in such a manner that it has a slight longitudinal movement, said strips constructed so that they can be moved to an angular position, one or more plates connected with the inner surface of each of said strips and provided with a beveled edge, projections on the window-frame adapted to engage the beveled edges of said plate when the strips are moved to their normal position and force said strips against the side of the frame.

4. A window-frame provided with grooves at the sides thereof, in which fit the window-sash, a portion of each groove associated with a movable part and adapted to be moved to an angle with the frame, an arm pivotally connected to each of said movable parts and provided with a projecting piece, adapted to engage a portion of the window-frame and hold the movable parts so that the parts of each groove are in line, said arm adapted to be moved about its pivotal point so as to project rearwardly from said movable parts and engage a portion of said frame when the parts are moved to an angular position so as to hold said parts and prevent them from returning to their normal position.



605,886. DISH-DRAINER. MARIN I. PERROTTET, New York, N. Y. Filed Oct. 11, 1897. Serial No. 654,891. (No model.)

Claim.—1. A dish-drainer comprising a reservoir, a tray fitted in the reservoir, provided with openings in its bottom, deflecting plates or partitions adjacent to one of the walls of the said openings, and cross-bars located above and between the deflecting-plates, as and for the purposes specified.

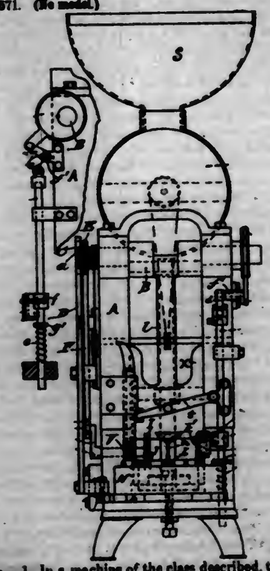
2. A dish-drainer consisting of a reservoir adapted to receive water, a tray supported by the reservoir, the tray being provided with openings in its bottom and deflecting-plates at one side of the said openings, cross-bars located above and between the said plates, and shelves hinged to the sides of the reservoir and adapted to fold upward against the tray, and swing-supports arranged for engagement with the bottom portions of the shelves to hold the said shelves in a substantially horizontal position, for the purpose specified.

605,887. LOCK. GEORGE L. B. PIERCE, San Francisco, Cal. Filed Mar. 10, 1898. Serial No. 673,594. (No model.)

Claim.—1. A lock, comprising a sliding bolt, and a pivoted and spring-pressed yoke-shaped locking-lever provided with a central body, one portion of which has an interlocking engagement with the bolt, and the other portion extending to within a short distance of the keyhole, substantially as described.

2. A lock, comprising a sliding bolt, and a pivoted and spring-pressed yoke-shaped locking-lever provided with a central body, one portion of which has an interlocking engagement with the bolt and the other portion extending to within a short distance of the keyhole and provided with pins on one face, substantially as and for the purpose set forth.

3. A lock, comprising a casing, a sliding bolt provided with notches on opposite sides, a yoke-shape lever having its members loosely pivoted in supports on the casing and provided with a central body, one portion of which is provided with a pin engaging one set of notches of the bolt, the other portion of the body extending to within a short distance of the keyhole and provided on one face with pins, and a spring between the said body and casing, substantially as described.



4. A lock, comprising a bolt, having locking projections, a yoke-shaped locking-lever pivoted to swing upon pivots substantially parallel to the bolt, and adapted to engage at its free end said locking projections upon the bolt, a central arm or body projecting near the keyhole and adapted to be engaged by the key before the latter engages the bolt to throw it, and a spring adapted to normally hold said lever in locking engagement with the bolt, in combination with a key having lockings upon the edges of its bit, adapted as the key is rotated, to engage said lever and raise it free of the bolt before engaging the bolt to throw it, substantially as described.

5. A lock, comprising a bolt having locking projections thereon, a yoke-shaped locking-lever pivoted to swing upon pivots substantially parallel to the bolt and adapted to engage at its free end said locking projections upon the bolt, a central body projecting from the yoke-shaped lever near the keyhole and adapted to be engaged by the key before the latter engages the bolt to throw it, said central body having downwardly-projecting pins disposed across the same, and a spring adapted to normally hold said lever in locking engagement with the bolt, in combination with a key having a blade cross-shaped or formed with a central cross-web, the end corners of said cross-web being inclined and adapted to engage said lever to swing it free of the bolt before engaging the bolt to throw it, substantially as described.

6. A lock, comprising a bolt provided with means for engagement of a locking-lever and a key therewith, pivot-flanges at one side of the bolt extending substantially at right angles thereto, said flanges having each an undercut notch, a yoke-shaped lever having its arms adapted to fit within said flanges and having pins at the ends of said arms adapted to enter the notches in said flanges, the other end of said lever being adapted to engage and lock the bolt, and the lever being adapted to be engaged by the key and swung upon its pivot to free the bolt, substantially as described.

7. A lock, comprising a bolt provided with means for engagement of a locking-lever and a key therewith, pivot-flanges at one side of the bolt extending substantially at right angles thereto, said flanges having each an undercut notch, a yoke-shaped lever having its arms adapted to fit within said flanges and having pins at the ends of said arms adapted to enter the notches in said flanges, the other end of said lever being adapted to engage and lock the bolt, and the lever being adapted to be engaged by the key and swung upon its pivot to free the bolt, the pivot-flanges having retaining-lugs at the end opposite the pivot-notch, and the yoke having shoulders engaging said lugs, to prevent longitudinal movement of the yoke, substantially as described.

605,888. MACHINE FOR HEADING CARTRIDGE-SHELLS. WILLIAM B. PLACE, King's Mills, Ohio. Filed Nov. 20, 1891. Serial No. 412,571. (No model.)

Claim.—1. In a machine of the class described, the combination of the extractor with the lever having one of its ends connected with said extractor and its other end pivoted to the frame and its fulcrum secured to a sliding head connected to the main shaft, substantially as and for the purpose set forth.

2. In a machine of the class described, a combined reducing and crimping mechanism consisting of a sleeve and rod fastened through the sleeve and limited in its downward movement, a spring normally pressing the rod downward, and a die internally formed so as to reduce and crimp the end of the shell, such die resting against the spring-pressed rod, and mechanism connected with the main shaft for actuating the reducing and crimping mechanism, substantially as and for the purpose set forth.

3. In a machine of the class described and in combination with a wad-gage, a shell-case crimper, a head-setting plunger and an extractor, a revoluble shell-case-carrying dial, shell-case supports arranged therein comprising two portions elastically supported with reference to each other, and means arranged in the path of revolution of said dial for projecting said supports above the surface of said dial during the action of said wad-gage, crimper and extractor and for withdrawing said support below the surface of said dial during the action of said head-setting plunger, as and for the purpose set forth.

4. In a machine for heading cartridge shells, the combination with a vertically-disposed hopper adapted to receive the caps or heads therein, a revoluble disk having rotating corrugations in said hopper and forming one wall of the cap or head receiving chamber a vertically-arranged chute or raceway, all of size adapted to receive the heads or caps in single file, and connected at its upper end with the cap or head chamber of the hopper, a spring-pressed plunger arranged to project transversely across the lower end of said raceway and forming a cut-off for the column of caps or heads contained therein, a shell case carrier, means for depressing said plunger and for receiving and transferring a head or cap from said raceway to said carrier, and means for applying the transferred head to the end of the shell-case, substantially as and for the purpose set forth.

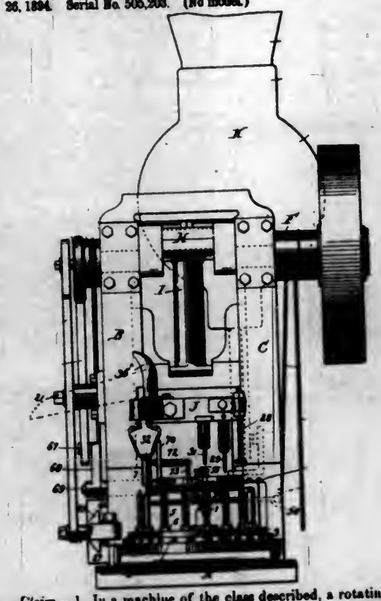
5. In a machine of the class described, the combination with a vertically-disposed hopper, a revoluble disk mounted therein and forming one wall of a chamber adapted to receive the caps or heads, a vertically-arranged chute or raceway communicating at its upper end with said chamber, means yieldingly mounted for supporting a column of caps or heads in said chute or raceway, a shaft arranged adjacent to the lower end of said raceway, clamping-fingers mounted thereon to rock therewith, and adapted to receive and transfer the heads or caps from the raceway to the shell-cases, a main operating-shaft and eccentric mounted thereon, a pivotally-mounted lever arranged to be engaged and rocked by said eccentric and means actuated by the rocking motion of said lever for imparting a quarter-revolution and return to said clamping-finger-supporting shaft, as and for the purpose set forth.

6. In a machine of the class described, a revoluble dial, a series of shell-case supports arranged therein, said supports comprising an exterior sleeve and an interior pin and a spring interposed between said sleeve and pin, a stationarily-held cam arranged in the path of travel of the shell-case supports and adapted to elevate and depress said supports as said dial revolves, as and for the purpose set forth.

7. In a machine of the class described, a framework, a shell case-feeding mechanism, a main driving-shaft mounted in said framework, a plunger-head arranged to be actuated by said shaft, a shell-case head-setting mechanism mounted on said plunger-head, a fixed guide mounted on said framework, a rod mounted to slide in said guide, a spring arranged to maintain said rod yieldingly in elevated position, a rocking shaft mounted in said framework and having an arm arranged to engage said rod, an eccentric mounted on said main shaft and connected to a crank-arm on said rocking shaft, whereby when said main shaft is actuated said rod is depressed against a yielding resistance, and a shell-case crimping-die carried by said rod, as and for the purpose set forth.

8. In a machine of the class described, a head-setting mechanism, a head-feeding device and means for transferring the heads from said feeding device to said setting mechanism and for holding and guiding the same during the action of said setting mechanism comprising two pairs of clamping-jaws superposed the one pair upon the other, a rocking support for said clamping-jaws, means for simultaneously opening both pairs of jaws to receive a head, and means for rocking said support comprising a pivotally-mounted lever, means for rocking the same about its pivot and connections between said lever and support, as and for the purpose set forth.

9. In a machine of the class described, the combination with a chute or raceway adapted to receive a column of heads or caps, a plunger mounted to reciprocate transversely therethrough, a spring arranged to yieldingly maintain said plunger in position to form a support for the column of heads, clamping-fingers and means for actuating the same, as and for the purpose set forth.



10. In a machine of the class described, the combination with a plunger-head and head-setting devices carried thereby, of a plunger-rod, a crimping-die carried thereby and arranged to crimp the end of the shells preparatory to receiving the heads thereon, means for projecting said rod longitudinally, whereby said crimping-die is advanced to its work, and means for yieldingly resisting the longitudinal projection of said rod and for returning the same to normal position, as and for the purpose set forth.

11. In a machine of the class described, a chute, a support for the end of said chute, a spring-pressed cut-off device carried by said support, said cut-off device cut away upon its upper surface and adapted to be projected across the end of said chute, a pivotally-mounted head-transferring device, means for rocking the same, said head-transferring device adapted to be rocked to engage and force said cut-off device back out of the line of travel of the heads in said chute, thereby permitting the head to drop into the jaws of the transferring device, as and for the purpose set forth.

12. In a head-assembling machine, a chute, a pivoted finger at the end thereof, a movable support for the column of heads and a pivotally-mounted head-transferring device and means for rocking the same, all combined and arranged, as and for the purpose set forth.

605,839. MACHINE FOR PRIMING OR CAPPING HEADS OF CARTRIDGE-SHELLS.

WILLIAM B. PLACE, King's Mills, Ohio, assignor to the Peters Cartridge Company, Cincinnati, Ohio. Filed Mar 26, 1894. Serial No. 505,203. (No model.)

Claim.—1. In a machine of the class described, a rotating cap-feeding table, a feed-chute, means for delivering the caps from said chute to said table in a single column, and a reciprocating device for feeding the caps singly from the end of said column upon said table, and placing them in position to be inserted in a head, as and for the purpose set forth.

2. In a machine of the class described, a cap-feeding table horizontally arranged and provided with a groove, a vertical feeding-chute arranged to deliver the caps upon said table and into said groove in a single column, and reciprocating placing mechanism, as and for the purpose set forth.

3. In a machine of the class described, a rotating cap-feeding table, a grooved plate, a feed-chute arranged to deliver the caps to said table and within the groove in said plate, and reciprocating placing mechanism, as and for the purpose set forth.

4. In a machine of the class described, a cap-feeding table, a cap-feeding chute arranged to deliver the caps upon said table in a single column, a cap-placing mechanism comprising a head having clamping-jaws, one of said jaws being pivoted thereto, and means for reciprocating said head transversely the column of caps upon said table, said pivoted clamping-jaw having a prolonged end whereby said jaws are opened to receive a cap, as and for the purpose set forth.

5. In a machine of the class described, cap feeding and placing mechanism comprising a continuously-rotating table, a stationary grooved plate, and a head having clamping-jaws adapted to reciprocate across the top of said table and transverse to the groove in said plate, and means for delivering the caps singly to said table and within said groove, as and for the purpose set forth.

6. In a machine of the class described, a stationary grooved feeding-plate provided with a yielding part in the wall of said groove, as and for the purpose set forth.

7. In a machine of the class described, a stationary grooved feeding-plate having a portion of the wall of said groove cut away, in combination with a spring-supported lip or tongue adapted to be received in said cut-away portion as and for the purpose set forth.

8. In a machine of the class described, a cap placing device comprising a head, a plate secured to said head and grooved or cut away in one of the projecting corners thereof, a spring-pressed jaw pivoted to said head, said jaw provided with an extended end and also grooved to correspond with the groove in said plate and adapted to form therewith a clamp, and means for reciprocating said head, and means adapted to engage the extended end of said pivoted jaw at the limit of movement of said head, whereby it is rocked about its pivot to open said jaws, as and for the purpose set forth.

9. In a machine of the class described, a main driving-shaft, a rotary eccentric mounted thereon, a reciprocating cap-placing clamp and means operated by said eccentric for reciprocating said clamp, as and for the purpose set forth.

10. In a machine of the class described, a main driving-shaft, an eccentric and strap mounted thereon, a lever pivoted intermediate its ends and connected at one end to said strap, a cap-placing clamp and means operated by the other end of said lever for reciprocating said clamp, as and for the purpose set forth.

11. In a machine of the class described, a rock-shaft, a slotted crank-arm carried thereby, a cap-placing clamp, a link pivoted at one end to the clamp and at the other end attached to said slotted crank-arm, and means for rocking said rock-shaft, whereby said clamp is reciprocated, as and for the purpose set forth.

12. In a machine of the class described, a feeding-chute having an enlarged chamber, a cap-agitating disk arranged in said chamber having a flanged crank-arm connected to the hub thereof, a rod adapted to pass through a perforation in said flange and having collars, springs interposed between said flange and collars, and means for reciprocating said rod comprising a rotating shaft and a crank-arm thereon, all combined and arranged as and for the purpose set forth.

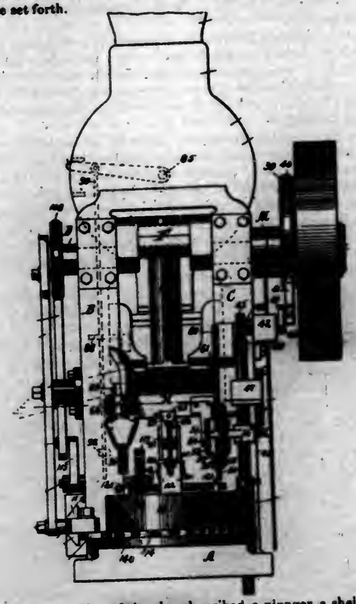
13. In a machine of the class described, the combination with a table having a perforation therethrough, of a punch arranged to operate in line with said perforation, and a shell-supporting pin adapted to present the shells to the action of said punch, said pin provided with a central longitudinal bore therethrough increasing in size from one end to the other, as and for the purpose set forth.

14. In a machine of the class described, a shell-feeding disk provided with suitably-spaced screw-threaded perforations through the outer rim thereof, and longitudinally-bored shell-supporting pins screw-threaded at the lower end, to be received in said screw-threaded sockets, as and for the purpose set forth.

15. In a machine of the class described, a feeding-chute, an agitating-disk arranged therein, a flanged crank-arm connected to said disk, a rod arranged to pass through a perforation in said flange, means for reciprocating said rod and springs interposed between said rod and flange, as and for the purpose set forth.

16. In a machine of the class described, a cap-feeding device comprising a table, means for delivering the caps thereto in a single column, a reciprocating clamp having a pivoted jaw adapted to grasp the caps singly from the end of said column, and to place them in position to be inserted in a shell, and connections for reciprocating said clamp, as and for the purpose set forth.

17. In a machine of the class described, a main driving-shaft, a reciprocating cap-feeding device comprising a clamp having a pivoted jaw, means for reciprocating said device from said shaft, a cap-feeding chute arranged to deliver the caps to said feeding device in a single column, means actuated by said main shaft for feeding the caps singly down said chute, and means whereby the pivoted jaw of said clamp is opened at one limit of movement of said clamp to receive a cap therein, as and for the purpose set forth.



605,840. MACHINE FOR ASSEMBLING HEADS OF CARTRIDGE-SHELLS.

WILLIAM B. PLACE, King's Mills, Ohio, assignor to the Peters Cartridge Company, Cincinnati, Ohio. Filed Mar. 26, 1894. Serial No. 505,204. (No model.)

Claim.—1. In a machine of the class described, a plunger-head, a head-setting die carried thereby, a plunger rod, a shell-crimper carried thereby, shell feeding and extracting devices, means for reciprocating said plunger-head and means for reciprocating said plunger-rod independently of the reciprocations of the plunger-head, as and for the purpose set forth.

2. In a machine for placing heads on cartridge-shells having the wads previously inserted therein, a reciprocating plunger-head, a head-setting die carried thereby, shell-case feeding and extracting devices, and means for actuating these several parts, in combination with an independent plunger, a gage carried thereby and arranged to gage the depth of the wads in the shell-cases in advance of the action of the head-setting die and means for reciprocating the said independent plunger, as and for the purpose set forth.

3. In a machine of the class described, a driving-shaft having an eccentric disk mounted thereon, a strap for said disk, a plunger-rod, a crimping-die carried thereby, means operated by said eccentric-strap for moving said rod and a yielding resistance against which said rod is moved and adapted to return the same, as and for the purpose set forth.

4. In a machine of the class described, a plunger, a shell-crimping die carried thereby, yielding means for normally keeping said plunger elevated, means for periodically advancing said plunger against said yielding resistance, a head placing and setting mechanism, and shell extracting and feeding devices, all combined and arranged as and for the purpose set forth.

5. In a cartridge-shell-head-assembling machine, a plunger-head, carrying a head-setting die and a shell-extractor a rod independent of said plunger-head, a crimping-die carried thereby, a shell-feeding mechanism and means for independently operating said plunger head, rod and feeding mechanism, as and for the purpose set forth.

6. In a machine of the class described, a plunger-rod, a shell-crimping die carried thereby, devices for moving said plunger in one direction to its work and a yielding resistance arranged to oppose said movement and normally acting to return said plunger, a plunger-head carrying a setting-die, a shell-extractor and a shell-feeding mechanism, all combined and arranged as and for the purpose set forth.

7. In a cartridge-head-assembling machine, a grooved, reciprocating plunger, a crimping-die carried thereby, a stationarily-held feathered box through which said plunger reciprocates, means for reciprocating said plunger, and cartridge-shell-feeding mechanism, all combined and arranged as and for the purpose set forth.

8. In a machine of the class described, a reciprocating plunger-head, shell-extracting and head-setting mechanisms carried thereby, a plunger-rod, shell-crimping mechanism carried thereby, and means for moving said plunger-rod independently of the reciprocations of the plunger-head, and a yielding resistance against which said rod is moved, as and for the purpose set forth.

9. In a machine of the class described, a plunger, a block adjustably supported by said plunger, a shell-crimping device carried thereby, means for moving said plunger, a yielding resistance against which said plunger is moved, shell feeding and extracting devices and head placing and setting mechanism, all substantially as and for the purpose set forth.

10. In a machine of the class described, a plunger, a block adjustably carried thereby, a crimping-die and a wad-gage carried by said block, reciprocating head-setting and shell-extracting devices, shell-feeding devices and means for moving said plunger against a yielding resistance independent of the reciprocations of the head setting and extracting devices, as and for the purpose set forth.

11. In a machine of the class described, a plunger adapted to be periodically moved against a yielding resistance, a crimping-die and a wad-gage adjustably carried thereby, and means for securing a yielding motion of said gage, as and for the purpose set forth.

12. In a machine of the class described, a plunger adapted to be

moved periodically against a yielding resistance, a block adjustably carried thereby, a crimper-die carried by said block, a wad-gage yieldingly supported by said block, all in combination, as and for the purpose set forth.

13. In a machine of the class described, a plunger, a hollow crimper-die carried thereby, a shell-stripper stationarily held and adapted to be projected longitudinally through said hollow die and means for moving said plunger positively in one direction and a spring arranged to return said rod to its normal position, as and for the purpose set forth.

14. In a machine for placing heads on cartridge-shells having the wads previously placed therein, a reciprocating plunger-head, a head-setting die carried thereby, means for reciprocating said plunger-head, a shell crimper and stripper arranged in advance of the head-placing mechanism, an independent reciprocating plunger, a wad-gage carried thereby and adapted to gage the depth in the shells of the wads previously placed therein, means for actuating said independent plunger, and shell-extracting mechanism, all combined and arranged as and for the purpose set forth.

15. In a machine of the class described, a short shaft journaled in a stationary bearing and having a crank-arm on each end thereof, means connected with one of said crank-arms for rocking said shaft, a plunger adapted to be moved by the other of said arms against a yielding resistance, a crimping-die and a wad-gage carried by said plunger, all combined and arranged as and for the purpose set forth.

16. In a machine of the class described, a main shaft, an eccentric mounted thereon, an eccentric-strap mounted on said eccentric and provided with a pitman, a spring-supported plunger adapted to slide in a stationary bearing, a rock-shaft journaled in a stationary bearing and provided with a crank-arm on each end thereof, one of said crank-arms connected to said pitman and the other adapted to contact with said plunger and force the same in a direction opposed to its spring-supports, as and for the purpose set forth.

17. In a cartridge-shell-head-assembling machine, the combination with wad-gaging, shell-crimping, head-setting and shell-extracting mechanisms of a shell-feeding mechanism for successively presenting a shell to said several mechanisms, comprising a dial having sockets formed therein and having a continuous groove upon the under side thereof, pins loosely mounted in said sockets, a cam-surface stationarily mounted and arranged to be received in said groove and upon which said pins are supported, whereby when said dial is rotated, said pins are projected or retracted, and means for rotating said dial, as and for the purpose set forth.

18. In a cartridge-shell-head-assembling machine, the combination with a plunger, a wad-gaging device and a shell-crimping device actuated thereby, a reciprocating plunger-head, shell-case-head setting and extracting devices actuated thereby, of means for successively presenting the shell-cases to said several devices, comprising a dial, pins carried thereby and means for projecting said pins and withdrawing the same to properly present the shell-cases, and means for rotating said dial, as and for the purpose set forth.

19. In a cartridge-shell-head-assembling machine, the combination with a plunger, wad-gage and shell-crimping devices carried thereby, and a reciprocating plunger-head, head-setting and shell-extracting devices carried thereby, of means for successively presenting a shell-case to said several devices, comprising a shell-carrier having sockets formed therein, pins loosely mounted in said sockets, cam-plates mounted in the path of travel of said sockets upon which said pins are supported, and means for actuating said carrier, as and for the purpose set forth.

20. In a cartridge-shell-head-assembling machine, the combination with wad-gaging, shell-crimping, head-setting and extracting devices, and means for actuating the same, of means for successively presenting the shells to said several devices, comprising a table, a shell-carrier mounted thereon and having a groove upon the under side thereof, sockets formed through said carrier and communicating with said groove, cam-plates stationarily mounted upon said table and arranged to register with and to be received in the groove in said carrier, pins loosely mounted in said sockets and arranged to rest upon said cam-plates, and means for actuating said carrier, as and for the purpose set forth.

21. In a cartridge-shell-head-assembling machine, the combination with wad-gaging, shell-crimping, head-setting and extracting devices, and means for actuating the same, of means for successively presenting the shell-cases to said several devices, comprising a table, a rotary dial arranged to rest thereon and having a circularly-arranged groove on the under side thereof, peripherally-arranged sockets formed through said dial and opening into said groove, cam-plates stationarily mounted on said table and arranged to project into said groove, pins loosely mounted in said sockets and arranged to rest on and to be supported by said cam-plates, and means for rotating said dial, as and for the purpose set forth.

22. In a cartridge-shell-head-assembling machine, the combination with wad-gaging, shell-crimping, head-setting and extracting devices, and means for actuating the same, of means for successively presenting the shell-cases to said several devices, comprising a table, a carrier arranged to rest thereon and having a groove or recess upon the under surface thereof, sockets formed through said carrier and opening into said groove, fixed cam-plates mounted on the top surface of the said table and arranged to project into said groove, headed pins arranged in said sockets and having the heads thereof arranged in said groove and resting upon said cam-plates, and means for actuating said carrier, as and for the purpose set forth.

23. In a cartridge-shell-head-assembling machine, the combination with wad-gaging, shell-crimping, head-setting and extracting devices and means for actuating the same, of means for successively presenting the shells to the said several devices, comprising a perforated table, a shell-case carrier mounted thereon, said carrier provided with sockets, pins loosely mounted in said sockets, said sockets and perforations being so relatively arranged as to be brought into register with each other when said carrier is suitably actuated, whereby said pins may be inserted in or withdrawn from said sockets, means for closing said perforations, cam-plates arranged in the path of travel of said carrier and upon which said pins are supported, and means for actuating said carrier, as and for the purpose set forth.

24. In a machine of the class described, a plunger, a head-setting die actuated thereby and means for feeding a head, in combination with a table, a shell-feeding device mounted thereon and arranged to present the shells to the action of said setting-die and a stationary support for the shell adjustably mounted in said table and arranged in line with the head-setting die, said support adapted to resist the action of said die, as and for the purpose set forth.

25. In a cartridge-shell-head-assembling machine, a head transferring and placing device, a shaft upon which said device is mounted, a gear-wheel mounted on said shaft and means for operating the same, comprising a rock-shaft, a gear-wheel mounted thereon and meshing with said first-mentioned gear and a rocking-lever for rocking said shaft, as and for the purpose set forth.

26. In a machine of the class described, a head-setting mechanism, a head transferring and placing device, a shaft upon which said device is mounted, a gear-wheel mounted on said shaft, a second gear-wheel meshing with the first mentioned gear and means for rocking said last-mentioned gear at each operation of said head-setting mechanism, as and for the purpose set forth.

27. In a machine for heading shells in which the wads have been previously placed, the combination with wad-gaging, shell-crimping, head-setting and extracting devices and a main shaft for actuating the same, of a head transferring and placing device and means for actuating the same, comprising a pivotally-mounted lever having connection at one end with said transferring device, an eccentric mounted on said main shaft and connections between said eccentric and the other end of said lever, as and for the purpose set forth.

28. In a machine for heading shells in which the wads have been previously inserted, a head-setting mechanism, a head-transferring device, a shaft for supporting the same, a rock-shaft, intermeshing gear-wheels respectively mounted on said shafts, and means for rocking said rocking shaft at each actuation of said head-setting mechanism, comprising an eccentric and a pivotally-mounted lever, as and for the purpose set forth.

29. In a machine of the class described, a head-setting mechanism, a head-transferring mechanism and supporting-shaft therefor, a rock-shaft, a gear-wheel mounted thereon for angular adjustment and adapted to mesh with a gear-wheel on the first-mentioned shaft and means for rocking said rock-shaft at each actuation of said head-setting mechanism, as and for the purpose set forth.

30. In a cartridge-shell-head-assembling machine, the combination of a reciprocating plunger, a head-setting die and shell-extracting devices carried thereby, means for actuating said plunger, means for crimping the ends of the shell-cases and means for presenting the heads to the said setting mechanism, comprising pivoted jaws having oppositely-beveled meeting projections or flanges and means for engaging said oppositely-beveled flanges for opening said jaws, as and for the purpose set forth.

31. In a cartridge-head-assembling machine, a reciprocating plunger, a head-setting die and shell-extracting devices carried thereby, means for actuating said plunger, a crimper and a wad-gage arranged in advance of said die and means for presenting the shell-cases to these several parts, in combination with means for presenting the heads to the said head-setting die comprising pivoted jaws having oppositely-beveled meeting projections or flanges, springs arranged to normally close said jaws and means for engaging said oppositely-beveled flanges for opening said jaws, as and for the purpose set forth.

32. In a cartridge-head-assembling machine, a reciprocating plunger a head-setting die and shell-extracting devices carried thereby, means for actuating said plunger, a crimper and a wad-gage arranged in advance of said head-setting die and means for successively presenting a shell-case to these several devices, in combination with means for presenting the heads to the action of said setting-die, comprising pivotally-mounted, spring-pressed jaws, having oppositely-beveled meeting projections or flanges, said jaws being cut away on their meeting edges to conform to the shape of the head, and means arranged to engage said oppositely-beveled projections or flanges upon said jaws, as and for the purpose set forth.

33. In a cartridge-shell-head-assembling machine, a shell-crimping device, a head-setting die, a shell-extracting mechanism, means for actuating these several parts, and means for successively presenting the shell-cases to the action of these several devices, in combination with a head-transferring device, comprising pivotally-mounted spring-pressed jaws having oppositely-beveled meeting projections or flanges, and an adjustably-fixed part arranged to enter the space between the beveled meeting edges of said flanges or projections when said jaws are rocked, whereby said jaws are forced apart, and means for rocking said jaws upon their pivotal support, as and for the purpose set forth.

34. In a machine of the class described, a crimper, a head-setting die, a shell-extractor, means for actuating these several devices, in combination with a rocking, head-transferring device comprising pivotally-mounted spring-pressed jaws arranged with the edges thereof opposed to each other, said edges provided with projections or flanges oppositely beveled on the meeting edges thereof, an adjustable pointed screw or pin arranged in the path of movement of said transferring device and adapted, when said jaws are rocked about their pivotal support, to enter the space between the beveled meeting edges of said projections or flanges, whereby said jaws are forced apart, and means for rocking said jaws, as and for the purpose set forth.

35. In a cartridge-head-assembling machine, a shell-crimping device, a head-setting die and a shell-extractor, means for reciprocating these several parts, and means for successively presenting the shells to the action of the several parts, in combination with means for feeding the heads to the said head-setting die, comprising a stationary raceway having a delivery-mouth and adapted to receive the heads in single column, a support for said raceway, a recess formed in said support adjacent to the delivery-mouth of said raceway, a yieldingly-mounted block arranged in said recess and normally held across the delivery-mouth of said raceway, and a head-transferring device arranged, when actuated, to displace said block from across the delivery-mouth of the said raceway, whereby the heads are permitted to pass singly from said raceway to said head-transferring device, and means for actuating said head-transferring device, as and for the purpose set forth.

36. In a machine of the class described, a feeding-chute comprising a stationary chamber having a mouth, a removable tray adapted to receive the articles to be fed and to be telescoped into the mouth of said stationary chamber to deliver the articles therein, means for supporting the movable part in the mouth of said stationary part and means arranged within said chamber for agitating the heads contained therein, as and for the purpose set forth.

37. In a machine of the class described a feeding-chute, comprising a chamber, means for delivering the heads to said chamber with their open ends all presented in one direction, a raceway communicating with said chamber, a disk arranged in said chamber and means for rocking or agitating said disk, whereby the heads are prevented from clogging the mouth of said raceway, as and for the purpose set forth.

38. In a machine of the class described, a head-feeding chute comprising an enlarged chamber, a raceway communicating with the lower part of said chamber and a rocking disk mounted in said chamber and provided with a pin in the face thereof, and means for rocking said disk, as and for the purpose set forth.

39. In a machine of the class described, a feeding-chute comprising a chamber, a receiver communicating with said chamber, an agitating-disk arranged in said chamber, a reciprocating plunger and yielding connections between said plunger and disk for yieldingly rocking the latter, as and for the purpose set forth.

40. In a machine of the class described, a feeding-chute, an agitating-disk arranged to rock therein, a reciprocating plunger and yielding connections intermediate said plunger and said disk for rocking the latter, as and for the purpose set forth.

41. A head-feeding chute having an enlarged chamber, a rocking disk mounted therein, a crank-arm sleeved on the disk-support, a rod connected to said crank-arm, a reciprocating plunger, a perforated arm carried thereby, said rod adapted to pass through said perforation and springs interposed between said arm and collars on said rod, as and for the purpose set forth.

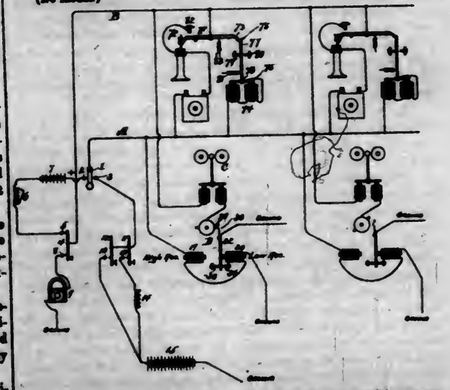
42. In a head-feeding device, a raceway adapted to receive a single column of heads, a slidable spring-pressed plunger normally held transversely across the mouth of said raceway and adapted to support said column of heads and a transferring device arranged to periodically engage said support and slide the same out of line with said column of heads, whereby said heads are delivered to said transferring device, as and for the purpose set forth.

43. In a head-feeding device, a raceway adapted to receive a single column of heads, a support for the said column of heads comprising a spring-pressed, cylindrical block provided with a flat upper side, as and for the purpose set forth.

44. In a machine of the class described, a raceway, a spring-pressed lip mounted thereon at the end thereof, a spring-pressed support for the column of heads contained in said raceway, and a head-transferring device adapted to force said support out of the line of travel of the heads in said raceway and to receive therefrom a single head, all combined and arranged as and for the purpose set forth.

45. In a machine of the class described, a plunger-head in combination with a shell-extracting mechanism mounted thereon, said extracting mechanism comprising loosely-mounted, gravity-operated blocks, as and for the purpose set forth.

46. In a cartridge-shell-extracting mechanism, a sleeve provided with oppositely-inclined passages and gravity blocks or pins loosely mounted therein, as and for the purpose set forth.



47. In a shell-extracting mechanism, a sleeve provided with oppositely-inclined passages and gravity-blocks loosely mounted therein, said blocks being beveled upon their opposing faces, as and for the purpose set forth.

48. In a shell-extracting mechanism, a reciprocating sleeve provided with oppositely-inclined passages and blocks loosely mounted to slide therein, said blocks being beveled on their meeting faces and provided with hooks at their lower ends, as and for the purpose set forth.

49. In a shell-extracting mechanism, a reciprocating plunger carrying a sleeve, said sleeve provided with oppositely-inclined passages, blocks loosely mounted to slide in said passages, means for guiding and supporting said blocks, said blocks being beveled on their inner or meeting faces and also on the ends thereof, and provided with hooks or shoulders, as and for the purpose set forth.

50. In a machine of the class described, the combination with a reciprocating, shell-crimping, head-setting and shell-extracting mechanism and means for operating the same, of shell-feeding mechanism and means for elevating the shells to the crimping mechanism, lowering the shells for the setting operation and again elevating the shells for the action of the extracting mechanism, as and for the purpose set forth.

605,841. TELEPHONE SYSTEM. ROBERT T. REES and JAMES L. MCDONNELL, Tacoma, Wash., assignors of one-half to Frank C. Corbin and John T. Bibb, same place. Filed Sept. 25, 1897. Serial No. 653,073. (No model.)

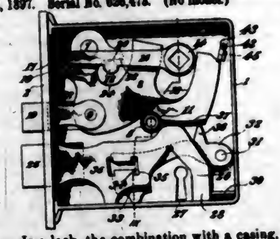
Claim.—1. In a telephone system, the combination with a party-line and subscriber's signal, of a controller for each signal, each controller having a normally open circuit-closer for controlling the circuit of the subscriber's signal, a step-by-step device for each circuit-closer, having a part adapted to move always in the same direction, an electromagnet of high resistance for operating said step-by-step device, a stop device adapted to arrest the circuit closer of each controller, a magnet of low resistance in series with the high resistance magnet for controlling said stop device and devices at the central office for controlling current through the coils of said magnets whereby to cause one signal controller at a time to close the circuit of the cooperating subscriber's signal, substantially as set forth.

2. In a telephone system, the combination with a party-line and subscribers' signals, of a controller for each signal, each controller comprising a circuit-closer in a normally open circuit for controlling the cooperating signal, stop devices, step-by-step devices having a part to move always in the same direction, an electromagnet for oper-

ating the circuit-closer and step-by-step devices, an electromagnet of lower resistance than the first-mentioned one for operating the stop devices to release the circuit-closer, said magnets being included in series with each other in a multiple-arc circuit and means at the central office for causing currents of different electromotive force to flow over the circuit of said electromagnets, substantially as set forth.

3. In a telephone system, the combination with a party-line and subscribers' signals, of a controller for each signal, each controller comprising a circuit closer for controlling the circuit of the cooperating subscriber's signal, a step-by-step device for operating said circuit-closer, an electromagnet for operating said circuit-closer, a stop device for the circuit-closer, an electromagnet for operating said stop device and of lower resistance than the first-mentioned magnet, coils of said magnets being arranged in series, a generator at the central office, a resistance at the central office and devices at the central office for including said resistance in the circuit of said magnets and battery at one time and for excluding said resistance from said circuit at another time, substantially as set forth.

4. In a telephone system, the combination with two conductors of a party-line and telephones included in parallel between said conductors, of a signal-controller at each subscriber's station, each controller comprising a normally open circuit-closer, step-by-step devices for operating said circuit-closer, high-resistance electromagnetic devices for operating said step-by-step devices, stop devices for the circuit-closer and low-resistance electromagnetic devices for controlling said stop devices and included in series with the high-resistance electromagnetic devices, a signal in a multiple-arc circuit from one of the line conductors to the ground and including said circuit-closer, devices at the central office for causing currents of different electromotive force to flow over the circuit of said electromagnetic devices, and means for causing a pulsatory current to pass over the circuit of the multiple-arc circuit including the subscriber's signal and circuit-closer, substantially as set forth.



5. In a telephone system, the combination with a party-line and subscribers' signals, of a controller for each signal, each controller comprising a circuit-closer, a step-by-step device for operating said circuit-closer, a lock device for the circuit-closer, electromagnets for the step-by-step devices and the lock devices respectively, a signal-transmitter at the central office comprising a make-and-break wheel, an arm carried thereby, a contact-arm to engage the make-and-break wheel, a lock-lever for the arm carried by the make-and-break wheel, means for stopping said arm and the make-and-break wheel at the desired point, a normally open circuit including one line-wire, the make-and-break wheel, the contact-arm which cooperates therewith, a resistance and a battery, a contact-arm connected with said line-wire and adapted to be engaged by said first-mentioned arm whereby to short-circuit the resistance and a normally closed circuit including both line-wires, a battery, an annunciator, the lock-lever, the first-mentioned arm the make-and-break wheel and the resistance, substantially as set forth.

6. In a telephone system, the combination with a party-line and subscribers' signals, of a controller for each signal each controller comprising a step-by-step circuit-closer, a lock device, an electromagnet of high resistance to operate the step-by-step circuit-closer, an electromagnet of low resistance to operate the lock and complete the circuit through the circuit-closer and signal, a transmitter at the central office for operating said signal-controllers, said transmitter comprising a motor, a make-and-break wheel and a double arm carried by the shaft of said motor, a contact-arm cooperating with said make-and-break wheel, said contact-arm and make-and-break wheel being included in a normally open circuit with a battery, a resistance and one of the line-wires, a locking-lever for the double arm, a contact-arm connected with said line-wire and cooperating with the double arm to short-circuit said resistance, a plate having a series of sockets or perforations, a metallic pin to enter one or another of said sockets or perforations whereby to stop the double arm and make-and-break wheel, an electromagnet included in circuit with said plate and said line-wire and an armature-lever for said magnet included in a normally open circuit with the other line-wire and a magneto generator, substantially as set forth.

7. In a telephone system, the combination with the conductors of a party-line, of a series of telephones arranged in parallel between said conductors, a switch-arm for each multiple-arc telephone-circuit, an electromagnet, a polarized armature for said magnet, an arm on said armature normally disposed under one end of said switch-arm, and a circuit in parallel with the telephone-circuit and including said electromagnet, the arm on the armature thereof and said switch-arm, substantially as set forth.

8. In a telephone system, the combination with the conductors of a party-line, of a series of telephones arranged in normally open circuits in parallel between the line conductors, a switch-arm or hanger forming part of each telephone-circuit and beveled at one end, an electromagnet, a polarized armature therefor, an arm projecting from said armature and having a tooth at its free end normally disposed under the beveled end of the switch-arm or hanger and a circuit in parallel with the telephone-circuit and including said electromagnet, the arm on the armature thereof, the switch-arm or hanger and said line conductors, substantially as set forth.

605,842. LOCK. HENRY B. RICHARDSON, Keytesville, Mo. Filed Mar. 8, 1897. Serial No. 626,473. (No model.)

Claim.—In a lock, the combination with a casing, of a counterweight pivoted at its upper forward corner within the upper forward corner of the casing and extending rearwardly adjacent to the rear wall of the casing, a latch-bolt pivotally secured to the lower forward corner of the counterweight, counterweight-actuating mechanism having positive connection with said counterweight, a lock-bolt, a tumbler pivoted at its rear extremity adjacent to the rear wall of the casing and operatively connected with the lock bolt, said tumbler being limited in its downward movement by contacting with the lower wall of the casing, an upwardly-extending projection upon the tumbler adjacent to its pivot and in positive contact with the extreme rear end of the counterweight when the tumbler is in its lowest position, and a detent designed to lock the counterweight in position to confine the tumbler immovably between said counterweight and the lower wall of the casing whereby the entire assemblage of operative parts within the casing may be locked positively against movement, vibrational or otherwise, substantially as specified.

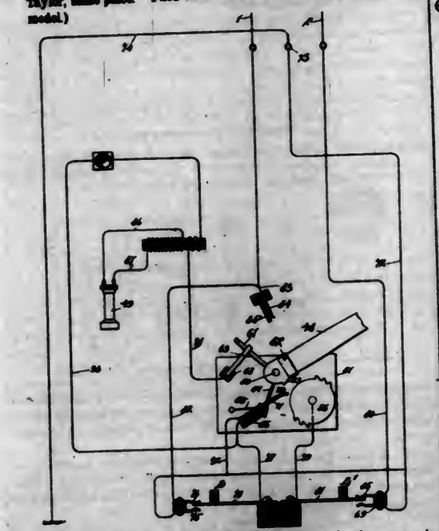
605,843. BAG-CLOSURE. ARCHIA L. ROSS, New York, N. Y., assignor of one-half to David Hyams, same place. Filed June 25, 1897. Serial No. 642,266. (No model.)

Claim.—1. A bag-closure, comprising a frame having two members pivotally connected with each other, and each formed of spring metal, one member being provided at or near its middle with a pivoted loop, and the other with a transversely-extending catch having a shoulder adapted to snap under the other frame member, between the members of the said loop to lock the members and keep the frame in a closed position, and a cord packing arranged on the inside of the frame and following the line of the members thereof, so that when the bag is closed, the said packing hermetically seals the mouth of the bag, substantially as shown and described.

2. A bag-closure, comprising a frame having two members pivotally connected with each other, and each formed of spring metal, one member being provided at or near its middle with a U-shaped keeper and the other with a transversely-extending catch formed by doubling a portion of the member, then bending the doubled-up portion and forming the same with a shoulder adapted to snap under the keeper of the other frame member, to lock the member and keep the frame in a closed position, a loop pivoted on the other frame member for suspending the bag and for conveniently opening the frame members and a cord packing on the inside of the frame and following the line of the members thereof, substantially as shown and described.

605,844. COMBINED BURGLAR-ALARM AND LOCK. CHAUNCEY R. SAMM, St. Louis, Mo., assignor of two-thirds to William B. Knight and Edward B. Knight, same place. Filed Jan. 8, 1896. Serial No. 666,018. (No model.)

Claim.—1. A burglar-alarm and lock comprising an alarm-box provided with a cartridge-receptacle, a locking-bolt adapted to be thrown into said alarm-box, a spring-controlled bolt having an arm and located in said box and normally retracted by said spring, a firing-pin carried by said arm, and a trigger carried by said box, adapted to bear on said locking-bolt and on said spring-controlled bolt and trip the latter, substantially as described.



2. A burglar-alarm and lock comprising an alarm-box provided with a cartridge-receptacle, a locking-bolt adapted to be thrown into said alarm-box, a spring-controlled bolt having an arm and located in said box and normally retracted by said spring, a firing-pin carried by said arm, a stud carried by said bolt, and a trigger carried by said box adapted to bear on said locking-bolt and on said stud and to trip said spring-controlled bolt, substantially as described.

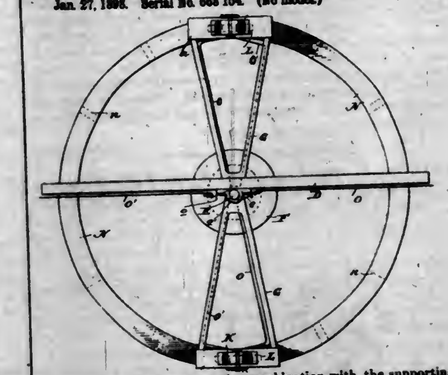
3. A burglar-alarm and lock comprising an alarm-box provided with a cartridge-receptacle and containing a recess in one of its sides, a locking-bolt adapted to enter said recess, a spring-controlled bolt having an arm and located in said box and normally retracted by said spring, a firing-pin carried by said arm, a guide-pin carried by said arm, and a trigger carried by said box and adapted to bear on said locking-bolt and on said spring-controlled bolt and trip the latter, substantially as described.

4. A burglar-alarm and lock comprising an alarm-box containing a cartridge-receptacle, a spring-controlled bolt having an arm and located in said box and normally retracted by said spring, a trigger carried by said box adapted to engage and trip said spring-controlled bolt, said box being provided with a recess in one of its sides, a locking-bolt adapted to enter said recess and contact with said trigger, said recess being of sufficient extent to permit sufficient travel of said locking-bolt to bear on said trigger and to trip said spring-controlled bolt, substantially as described.

605,845. CALL-BOX SYSTEM. EDGAR R. SALISBURY and ALBERT R. DEAN, Tacoma, Wash., assignors to themselves and Frank R. Taylor, same place. Filed June 22, 1897. Serial No. 641,773. (No model.)

Claim.—1. The combination of a signaling mechanism, comprising a call-box movement, a receiver, a supporting-lever mounted on the main arbor of said movement, a circuit-closer extended from the inner end of the lever, a contact-finger in the main line for engagement therewith, a circuit-closing switch for the main line comprising contact-fingers and adapted to be operated by the circuit-closer carried by the lever upon the downward movement of said lever, and connections comprising a grounding-switch between the main line and said circuit-closer carried by the lever, substantially as specified.

2. In a call-box system, the combination of a swinging hinge-lever for supporting a receiver, a call-box movement for moving said lever in one direction, a circuit-closer operated by said lever, circuit-closing fingers for the main line, means operated by a downward movement of the lever to operate said fingers and momentarily close the main line, and means comprising two switches for grounding and opening the circuit should the main line become inoperative, substantially as specified.



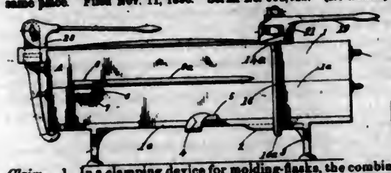
3. In a call-box system, a call-box mechanism comprising a lever containing a hinge and adapted to support a telephone-receiver, a movable insulating-block, and supporting circuit-closers arranged in a shunt-circuit from the main line and adapted to a change of position by engagement with the support-lever when said lever is at its extreme downward movement, substantially as specified.

4. A call-box mechanism, comprising a hinged receiver-supporting lever, a circuit-closing finger carried by the said lever and having connection with the main line, a fixed finger with which such movable circuit-closing finger is designed to engage, a wire extended from the fixed finger to a transmitter, the said wire comprising a resistance, a wire extended from the transmitter to another fixed contact-finger arranged for connection with the main line, means for closing a central office-signaling-device circuit upon a downward movement of the hinged lever, and a local circuit comprising a resistance and receiver, said resistance being wound in close proximity to the resistance contained in the wire leading to said transmitter, substantially as specified.

5. A messenger-call system, comprising main wires, a battery in the main wires for operating all the call-boxes, an ordinary call-box circuit, normally-closed contact-fingers arranged in said circuit, an auxiliary circuit 25, 36, 37, comprising a resistance and transmitter, and means for connecting said auxiliary circuit with the main-line wires, substantially as specified.

6. A messenger-call system, comprising main wires, a battery in the main wires for operating all the call-boxes an ordinary call-box circuit containing the usual apparatus for operating the same, normally-closed contact-fingers arranged in said circuit, an auxiliary circuit 25, 36, 37, comprising a resistance and transmitter, means for connecting said auxiliary circuit with the main-line wires, and a local circuit comprising a resistance and receiver, said resistance being wound in close proximity to the resistance of the auxiliary circuit, substantially as specified.

605,846. CAPSTAN. JAMES B. SAMPLE, Columbus, Ga. Filed Jan. 27, 1898. Serial No. 668,154. (No model.)



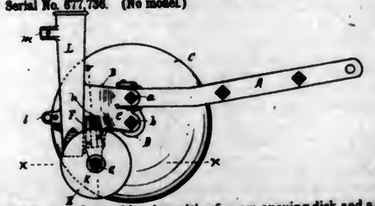
Claim.—1. In a capstan, the combination with the supporting-frame, of an upright shaft, sweeps connected to the shaft, a motor carried by the outer end of each of the sweeps, means for supplying the motors with motive power, drive-wheels driven by the motors and a track on which the wheels move, substantially as described.

2. In a capstan, the combination with a frame, of a vertical shaft loosely mounted therein, sweeps connected to the shaft and extending in opposite directions therefrom, platforms on the outer ends of the sweeps, a motor mounted on each of the platforms, a drive-wheel secured below each platform and having driving connections with the motor thereon and a circular track on which the drive-wheels move, substantially as described

3. The combination with a frame, of a vertical shaft mounted therein, a sweep fixedly secured to the shaft and extending outwardly therefrom, a motor on the outer end of the sweep, means for supplying the motor with motive power, a drive-wheel carried by the outer end of the sweep and having a gear connection with the motor, a circular track on which the wheel moves and a drum on the shaft.

605,847. HAND CLAMPING DEVICE FOR MOLDING-FLASKS.

JOSEPH SCHERER, Buffalo, N. Y., assignor to himself and John Heider, same place. Filed Nov. 11, 1896. Serial No. 611,712. (No model.)



Claim.—1. In a clamping device for molding-flasks, the combination with a longitudinal supporting-frame for supporting the operating parts and holding the top of the mold in place, of a head cross-bar carrying a cam at each end, substantially vertical arms having clamping-hooks at their lower ends and mounted in openings at each end of said cross-bar so that while their lower ends are capable of a free swinging movement to bring their hook ends toward or from the the sides of the flask they cannot turn out of the plane of their swinging movement, cam-arms mounted on the upper ends of the hook-arms adapted to turn horizontally thereon and engage with the cams for raising or lowering the hook-bars and simultaneously swinging their hooks toward or away from the flask, a clamping hook-arm at the opposite end of the clamping device, and means for operating it, substantially as described.

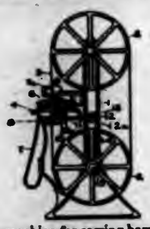
2. A molder's flask and clamping device therefor, comprising a flask formed in two sections, means for alining the sections when united, a supporting base or table having side projections, portions extending from the lower flask portion and engaging with the side projections of the table for limiting the forward longitudinal movement of said flask upon said table, a side clamping device having hooked arms for preventing transverse movement of the flask upon the table, and a forward clamp for preventing the rearward longitudinal movement of the flask upon the table, as set forth.

3. In a molder's flask and clamping device therefor, the combination with the flask formed in two separable halves and having means of alinement and wedge-shaped portions projecting from the lower half, of a supporting-base provided with a transverse ledge, longitudinal ledges, and hooks adapted to catch over the wedge portions projecting from the lower half, a cross-bar adapted to seat upon the top of the flask, a cam at each end of said bar, clamping-arms provided with hooks at their lower ends, adapted to fit over the longitudinal ledges, levers journaled to the upper ends of said clamping-arms and having portions adapted to travel upon the cams, a longitudinal bar or bars extending from the cross-bar to and over one end of the flask, a clamping-arm provided with a hook at its lower end adapted to fit over the transverse ledge and a lever for raising or lowering said clamping arms, as set forth.

605,848. SEEDING-MACHINE.

WALTER W. SCHULTS, Richmond, Ind., assignor to The Wayne Works, same place. Filed Apr. 15, 1896. Serial No. 577,736. (No model.)

Claim.—1. In combination with a furrow-opening disk and a seed-tube of a seeding device, the rotating guard-disk E journaled on an independent center, below and in rear of the center of the furrow-opening disk and opposite the mouth of the seed-tube, substantially as specified.



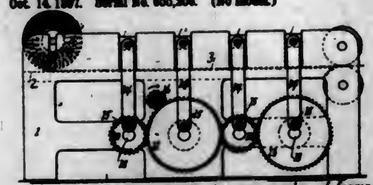
2. In a seeding device in combination with a furrow-opening disk journaled upon a hanger, and a seed-tube mounted thereon, the rotating disk-guard E journaled upon an independent center, below and eccentric to the plane of the furrow-opening disk, substantially as specified.

3. In a seeding device, in combination with a furrow-opening disk journaled upon a hanger, and a seed-tube mounted thereon, the rotating disk-guard E journaled upon an independent center, below and eccentric to the plane of the furrow-opening disk and having its forward edge in frictional contact with said furrow-opening disk, substantially as specified.

4. In a seeding-machine, in combination with a furrow-opening disk and a seed-tube connected to a hanger and a drag-bar support, a seed-guard disk journaled upon a secondary hanger detachably connected to the main hanger and having its center of rotation below and in rear of the axis of the furrow-opening disk, substantially as specified.

605,849. MACHINE FOR SAWING BARREL-HOOPS.

THEODORE C. SPENCER, Bay City, Mich. Filed Sept. 2, 1897. Serial No. 650,444. (No model.)



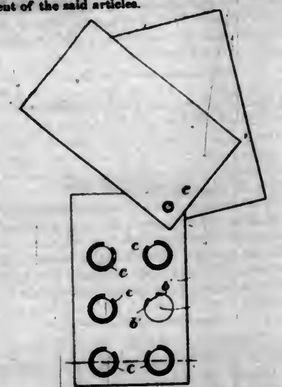
Claim.—1. In a machine for sawing barrel-hoops from poles, the combination with a band-saw having a horizontal sawing-table and a yielding whip-roller; of a yielding-surfaced guide-roller opposite the whip-roller, with its axis parallel with and at the side of the saw-teeth, said guide roller being adapted to be rotated toward the saw by connection with the band-wheel shaft, and serving both as a fulcrum about which the hoop may be swerved in sawing and also as a friction feeding-roller, substantially as described and for the purpose set forth.

2. In a machine for sawing barrel-hoops from poles, having a band-saw and a flexibly-mounted whip-roller; the combination feeding and guiding mechanism herein described, consisting of a vertical guide-roller at the side of the saw and substantially on the same transverse line with the saw-teeth and the axis of the whip-roller, forming a fulcrum about which to swerve the pole being sawed, and having a yielding surface adapted to seize the pole, said roller being rotated from the band-saw shaft and by the friction of its yielding surface feeding the pole at a speed proportional to the velocity of the saw, substantially as described.

3. In a hoop sawing machine, a combined feeding and guiding roller having a yielding surface for feeding the pole by frictional contact therewith, together with means of rotating said roller at a speed proportional to the speed of the saw, the roller being mounted substantially on a line with the teeth of the saw, and forming a fulcrum about which to swerve the pole in feeding, substantially as described.

605,850. PRINTING-PRESS.

ANOS H. SMITH, Brooklyn, N. Y., assignor of one-half to Frederick T. Van Hoesen, same place. Filed Oct. 14, 1897. Serial No. 655,206. (No model.)

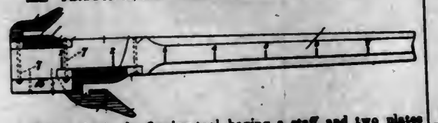


Claim.—1. A printing-press having a succession of forms, actuating-gears of varying diameters for the forms, and crank-pins and links for connecting the forms and gears, said crank-pins being placed equidistant from the centers or shafts of their respective gears substantially as described.

2. A printing-press having a succession of forms, a gear for each form, and crank-pins and links for connecting each form to its respective gear, said gears being made differential or variously speeded, substantially as described.

605,851. DISPLAY-CARD.

HENRY T. SMITH, Pawtucket, R. I., assignor to the Standard Seamless Wire Company, same place. Filed Nov. 11, 1897. Serial No. 658,194. (No model.)



Claim.—1. A display-card having orifices for the reception of articles to be held by the card, said orifices extending through the card, so that articles inserted therein are exposed at both sides of the card, and movable covers hinged to the card at opposite sides thereof, the axis of the hinge being at a right angle to the plane of the card so that the covers will swing in the plane of the card whereby both sides of the card may be simultaneously covered to secure the articles in said orifices, and simultaneously uncovered to permit the displacement of the said articles.

2. A display-card having orifices formed to receive curved articles, such as watch-bows, the said orifices having curved walls formed to bear on the outer surfaces of the watch-bows, and shoulders or abutments formed to bear on the ends of said bows.

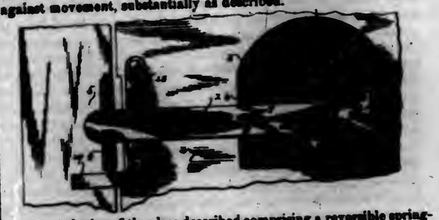
605,852. WIRE-FENCING TOOL.

JAMES R. SMITH, Jefferson, Ala. Filed Dec. 13, 1897. Serial No. 661,710. (No model.)

Claim.—1. A wire-fencing tool having a staff, and two plates rigidly secured to the head thereof, each plate having a hook thereon, and the hook of one plate having a recess therein capable of receiving the wire and of holding the wire to permit stretching the same, the other hook being capable of receiving the wire to handle the wire.

2. A wire-fencing tool having a staff, two plates respectively engaging opposite edges of the staff, each plate having a hook thereon, a clamping-plate overhanging one of the first-named plates, and fastening devices passing through the staff and through said plates to securely hold the same.

3. A wire-fencing tool having a staff, the head of which is provided with a recess, a plate rigidly secured in said recess and having the middle portion of its sides beveled oppositely with reference to each other, and a projection on the plate, the projection forming a hook thereon.



4. A wire-fencing tool having a staff provided with a recess, a plate secured in said recess, an arm or projection extending from the plate, the arm or projection forming a hook, and a clamping-plate rigidly secured against the staff and overhanging one end of the first-named plate, the clamping-plate having a recess receiving the base of said arm or projection.

605,853. COMBINED LATCH AND LOCK.

WILLIAM L. SMITH and HARRY M. PUTT, Huntingdon, Pa., assignors of one-third to Frank H. McGraw, same place. Filed Aug. 28, 1897. Serial No. 649,190. (No model.)

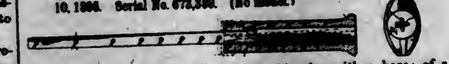
Claim.—1. A device of the class described comprising a casing provided at opposite sides with openings, a pair of pivots mounted within the casing and located adjacent to the openings, a reversible latch-bar provided between its ends with a pivot-opening and adapted to be arranged on either of the said pivots, the rear end of the latch-bar being arranged within the casing, and a spring connected with the casing and the rear portion of the latch-bar and adapted to swing to either side of the former to accommodate itself to the position of the latter, substantially as described.

2. A device of the class described comprising a casing provided at opposite sides with openings and having pivots arranged adjacent to the openings, a latch-bar provided between its ends with a pivot-opening to receive one of the pivots and having a transverse opening at its inner end to receive the other pivot, said latch-bar being reversible from one pivot to the other, and means for locking the latch-bar against movement, substantially as described.

3. A device of the class described comprising a reversible spring-actuated latch-bar, a casing receiving the same, a tumbler pivotally mounted in the casing and provided with a lug adapted to be swung into and out of engagement with the latch-bar, and a reversible stop adapted to be mounted at either side of the keyhole of the casing to limit the swing of the lug, substantially as described.

4. In a device of the class described, the combination with a keeper, of a guide designed to be mounted at the free edge of a gate and provided with a rigid arm extending beneath the keeper, a pivoted latch-bar mounted on the gate, passing through the guide and engaging the keeper, and means for locking the latch-bar against movement, substantially as and for the purpose described.

605,854. SELF-ADJUSTABLE BICYCLE-LAMP.



FRANK S. SNYDER, Brice, Ohio. Filed June 26, 1897. Serial No. 643,263. (No model.)

Claim.—A bicycle-lantern embracing the combination of a body part, an oil-reservoir, a ball connected with the reservoir, the said ball having a passage through which oil is supplied to the burner and a socket for the ball connected with the body of the lantern, substantially as described.

605,855. FENCE-POST.

JAMES H. SPARKS, Hobbieville, Ind., assignor of one-half to Asbury F. Mood, Buena Vista, Ind. Filed Mar. 10, 1898. Serial No. 673,389. (No model.)

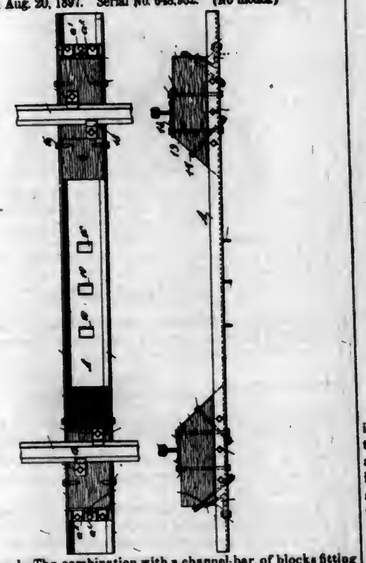
Claim.—1. In a fence-post, the combination with a base; of a post supported thereby and flat and tapering in cross-section, holes through the post, oblique slots cut from the thinner edge of the post into the holes, and fence-wires removably passing through the latter, substantially as described.

2. In a fence-post, the combination with a base having an aperture in its lower end leading upward to a shoulder and a slot in its upper end leading downward through the shoulder; of a post proper of a shape to fit said slot and having an eye at its lower extremity, a removable stop in said eye and of a size to pass into the aperture and strike the shoulder, and a fence supported by the post, as and for the purpose set forth.

3. In a fence-post, the combination with a base having an aperture in its lower end leading upward to a shoulder and a slot in its upper end leading downward through the shoulder, said slot tapering in width from one edge to the other; of a post proper of a shape to fit said slot and having an eye at its lower extremity, a removable stop in said eye and of a size to pass into the aperture and strike the shoulder, holes through the post where it projects above the base, fence-wires supported in said holes, and a key removably inserted in the lowermost hole at a point just above the upper end of the base, as and for the purpose set forth.

4. The herein-described fence-post base of clay or the like, the same consisting of a body substantially round in cross-section at its

upper end and oval in cross-section near its lower end, a bottom horizontal flange on said body, and upright side wings thereon, substantially as described.



5. The herein-described fence-post base of clay or the like, the same consisting of a body substantially round in cross-section, and upright wings on diametrically opposite sides of said body, said wings being beveled off at their upper ends and thinner at that point and growing thicker to their lower ends, substantially as described.

6. The herein-described fence-post base of clay or the like, the same consisting of a body substantially round in cross section at its upper end and oval in cross-section near its lower end, and upright wings on diametrically opposite sides of said body and corresponding with the longest diameter at its lower end, the outer edges of said wings standing on substantially parallel lines, substantially as described.

7. The herein-described fence-post base of clay or the like, the same consisting of a body substantially round in cross-section at its upper end and oval in cross-section near its lower end, and upright wings on diametrically opposite sides of said body and corresponding with the longest diameter at its lower end, the outer edges of said wings standing on substantially parallel lines and their bodies being thinner at their upper ends and thicker at their lower ends, substantially as described.

8. The herein-described fence-post base, the same comprising an upright body substantially round at its upper end and oval near its lower end, a horizontal bottom flange at its lower end, and upright side wings corresponding with the longest diameter of the body and extending from its upper end where the wings are thinner down to and merging into the flange at its lower end where the wings are thicker, the outer edges of said wings standing in parallel lines and the whole being of clay or the like, substantially as described.

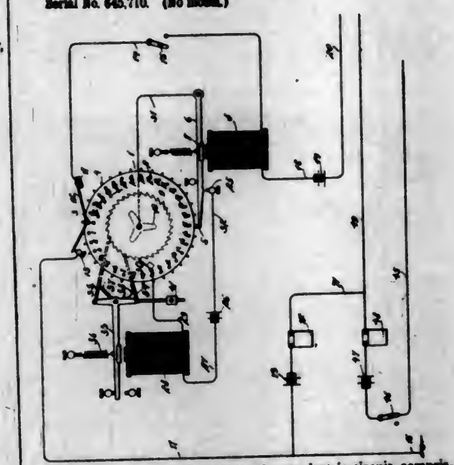
605,356. RAILWAY-RAIL TIE. EDWARD R. STILES, Decatur, Ill. Filed Aug. 20, 1897. Serial No. 648,932. (No model.)

Claim.—1. The combination with a channel-bar, of blocks fitting in said bar, each block having the lower portion of its outer end inclined upwardly and outwardly and its inner end inclined from top to bottom, shoes secured in the channel-bar and having an inclined face resting against the outer inclined portion of the block, and bolts extending through the blocks and bottom of the channel-bar, substantially as described.

2. The combination, with a channel-bar provided with fillets upon its inner face at its flanges, of blocks fitted to the said bar, each block having the lower portion of its outer end inclined, shoes secured to the said bar and fitting between the flanges thereof, the said shoes comprising a horizontal member and an inclined member engaging with the inclined portions at the outer ends of the blocks, clamps secured upon the upper surfaces of the blocks, and fastening devices auxiliary to the said shoes, arranged to hold the blocks firmly in engagement with the said channel-bar, as and for the purpose specified.

3. The combination, with a channel-bar having fillets formed upon its inner face at its flanges, portions of the bottom of the bar being struck downward forming anchors for the bars, of blocks fitted in the said channel-bar, shoes secured to the channel-bar between its flanges and having inclined faces engaging with the corresponding faces at the lower portion of the outer ends of the blocks, bolts passed through the blocks and through and beyond the bottom of the channel-bar, serving as auxiliary anchors for the bar, clamps adapted for engagement with the rails, secured upon the upper surface of the blocks nearer their inner than their outer ends, and bolts passed through the said clamps, through the blocks and through the bottom of the channel-bar, for the purpose set forth.

605,357. STEP-PAD. HENRY C. SWAN, Oshkosh, Wis. Filed Mar. 19, 1898. Serial No. 674,463. (No model.)



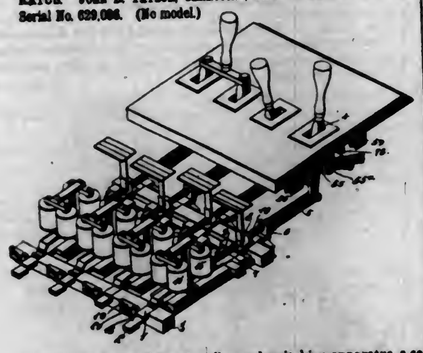
Claim.—1. The combination with a pad having a projecting lip, of a shank having its end arranged to fit under this lip and provided with a hole arranged to receive a bolt upon the pad.

2. The combination with a pad having an intermediate lip struck up therefrom and a bolt secured in said pad; of a shank having a flattened end portion arranged to fit under the lip, and a hole to receive the pad-bolt

---

605,358. SIGNALING DEVICE. FRANK B. TAYLOR, EDGAR E. SALISBURY, and ALBERT R. DEAN, Tacoma, Wash. Filed July 23, 1897. Serial No. 645,710. (No model.)

Claim.—1. A controlling device for an electric circuit, comprising a wheel having a number of stop-pins, an armature-lever adapted to engage with the respective stop-pins, an electromagnet located in a main circuit and coacting with said armature-lever, a local circuit in which the armature-lever is comprised and for which it serves as a circuit-closer, and a motor in the local circuit for operating the wheel, substantially as specified.



2. In a call-box, a controlling-wheel having a number of stop-pins, an armature-lever adapted to engage with the respective stop-pins, an electromagnet located in the main circuit at the central office and coacting with said armature-lever and a local circuit in which the armature-lever is comprised, the said armature-lever also forming an opening and closing switch for said local circuit, an electromagnet in said local circuit, a motor armature-lever coacting with said electromagnet, a ratchet-wheel movable with the stop-wheel, and a pair of ratchet-bars pivotally connected to the armature-lever and having yielding engagement with the ratchet-wheel, substantially as specified.

3. A central-office controlling device for an electric circuit having a number of call-boxes, comprising an indicator-wheel having a series of holes near its periphery, a series of pins extended radially from the periphery of the wheel, the number of pins being equal to that of the number of holes, a plug for insertion into either one of said holes, a spring contact-plate in the main circuit and adapted to be moved by said plug to break the circuit, an armature-lever actuated by the current through the main circuit, a local circuit in which said armature-lever is comprised, the said armature-lever forming a circuit-closer for the local circuit and also providing a stop for the indicator-wheel by engaging with one of its pins, an electromagnet in said local circuit, a motor armature-lever coacting with said electromagnet, a ratchet-wheel carried by the indicator-wheel, spring-pressed ratchet-bars pivotally connected to extensions from the motor armature-lever and engaging with the ratchet-wheel, and a retarding device for the wheels, substantially as specified.

4. In a call-box located in an electric circuit controlled from a central station, a wheel having a series of stop-pins, a contact-plate carried by said wheel, a motor located in a local circuit for rotating said wheel, a call-wheel having projections on its periphery corresponding to the number of the box, a local circuit for operating a motor to rotate said call-wheel, an armature-lever for closing said local circuit, and an electromagnet for drawing said armature to its closing position, the said electromagnet being located in the same circuit, the circuit through which is closed by the contact-plate carried by the first-named wheel, substantially as specified.

5. In a call-box, the combination with an electric circuit controlled from a male office, of a circuit-closing wheel, a motor for operating said wheel, comprising an electromagnet in a local circuit controlled from the main circuit, an armature-lever coacting with said electromagnet, a ratchet-wheel connected to the circuit-closing wheel, a ratchet-bar extended from the ratchet-wheel to a downwardly-extended arm of the armature-lever, another ratchet-bar extended from the ratchet-wheel to an upwardly-extended arm of the armature-lever, an adjustable pendulum-like governor for the motor, carried by the armature-lever, and a contact-plate having connection with the electromagnet and adapted for intermittent contact with the ratchet-wheel, to open and close the circuit through the electromagnet, substantially as specified.

605,359. RAILWAY SIGNALING AND SWITCHING APPARATUS. JOHN D. TAYLOR, Chillicothe, Ohio. Filed Mar. 24, 1897. Serial No. 629,096. (No model.)

Claim.—1. In a railway signaling and switching apparatus, a series of operating-levers, primary and secondary locking-bars, connections between the primary bars and levers, yielding connections between the primary and secondary bars, holding-latches for the secondary bars, and electrical means for releasing the latches, substantially as specified.

2. In a railway signaling and switching apparatus, a series of operating-levers, primary and secondary locking-bars arranged in pairs, one upon the other, connections between the primary bars and levers, spring-yielding connections between the pairs of bars, and electrically-actuated locking devices for the secondary bars, substantially as specified.

3. In a railway switching apparatus, a series of operating-levers, primary and secondary locking-bars arranged in pairs, one upon the other, link connections between the primary bars and levers, spring-yielding connections between the primary and secondary bars, two latches for controlling the opposite movements of each secondary bar, spring-pressed pawls, one at each end of each primary bar, adapted to engage notches in the primary bars and hold said primary bars until released by the secondary bars and electromagnetic means for lifting the latches and releasing the secondary bars substantially as specified.

4. A railway switching mechanism, comprising operating-levers, primary and secondary locking-bars, link connections between the primary bars and levers, spring-yielding connections between the primary and secondary bars, holding-latches for the secondary bars, electromagnets for raising the latches, and a switch-operating motor by means of which the magnets are energized at the proper time by currents generated by the rotation of the switch-motor momentum, substantially as specified.

5. In a railway-switch-operating mechanism, a series of operating-levers, circuit-closers carried by the levers, primary and secondary locking bars, link connections between the primary bars and levers, spring-yielding connections between the primary and secondary bars, holding-latches for the secondary bars, spring pressed pawls for holding the primary bars until the secondary have made complete movement, electromagnets for lifting the latches, and electric circuits comprising the switch-operating motor, an automatic electric reversing-switch operated by the motor, the circuit-closers attached to the operating-levers, the electromagnets and the electrical connections substantially as specified.

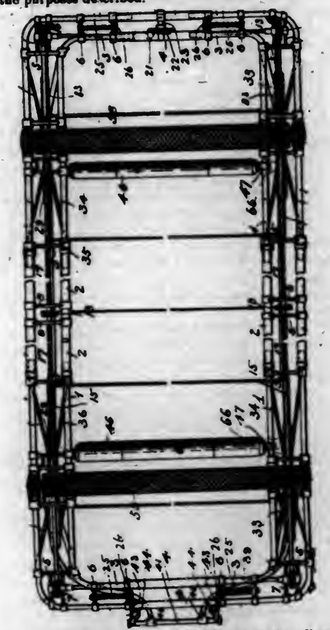
6. In a railway signaling apparatus, a signal, a motor for reversing the same, a counterbalanced lever for restoring the signal to normal position and rotating the motor in the reverse direction, a signal-operating lever, a two-position circuit-closer attached to the lever, a primary locking-bar, a secondary locking-bar, a link connection between the primary bar and lever, a spring-yielding connection between the two bars, a latch for controlling the movement of the secondary bar, and an electromagnet for raising said latch, the said magnet being in a circuit leading from the motor and energized by a current generated by the reverse rotation of the motor, substantially as specified.

7. In a railway signaling apparatus, two semaphores or signals, a motor, sheaves loosely mounted on the shaft of the motor, a clutch mechanism between said shaft and the sheaves, the said clutch mechanism operating to rotate the sheaves in opposite directions when the motor is reversed, and connections between said sheaves and semaphores or signals, substantially as specified.

8. A railway-signal, comprising two swinging signals, a motor for operating the same, two sheaves loosely mounted on the shaft of the motor, a single-toothed ratchet-wheel arranged at one side of each sheave, pawls carried by the sheaves for engaging the said teeth, counterbalanced levers on the support for the signals, connections between the sheaves and levers, and connections between the levers and signals, substantially as specified.

9. In a railway-signal-operating mechanism, two semaphores or signals, a reversible electric motor for operating the signals, a clutch mechanism on the shaft of the motor for selecting either one or the other signal depending on the direction of rotation of the motor, a polarized pole-changing relay for determining the direction of current through the motor-armature, a two-position circuit-closer attached to each of the two signal-operating levers, one for each signal, said circuit-closers acting conjointly to control the circuit through the polarized relay and severally to control circuits through the motor, a generator and the electrical connections, substantially as specified.

605,360. BURIAL APPARATUS. RICHARD H. THORNE, El Paso, Tex. Filed Mar. 2, 1898. Serial No. 672,253. (No model.)



Claim.—1. In a burial device, a frame composed of side members formed in sections and having a sliding connection with each other, end members formed in sections having a sliding connection with each other, and screws operatively connected with the sliding members for moving both the side and the end members and holding the same to their adjustment, and means for supporting a casket between the side and end members of the frame, substantially as and for the purposes described.

2. In a burial device, a frame composed of centrally-located stationary members at both the sides and ends of the frame, adjustable members extended along a portion of the sides and a portion of the ends of the frame and adjustably connected at their ends to the stationary members at the sides and the ends of the frame, and mechanically-operated means for simultaneously shifting the movable members either longitudinally or laterally for the purpose of varying the dimensions of the frame, substantially as and for the purposes described.

3. In a burial device, the frame composed of end and side members, the side members being formed in sections which have a sliding connection with each other, screw-shafts provided with gear-wheels and formed with right and left handed threads which engage with the movable sections of the side members so as to adjust the same longitudinally, rotatable shafts located adjacent to said screw-threaded shafts and provided with gear-wheels adapted to be thrown into and out of gear with the wheels on the screw-shafts, a shaft extending transversely at the end of the frame and provided with gear-wheels engaging with wheels on the rotatable shafts at the sides of the frame, and means for rotating said end shaft so as to transmit motion to the rotatable side shafts and the adjusting-screws, substantially as and for the purposes described.

4. In a burial device, the frame composed of the side and end members, the end members having a sliding connection with each other to permit lateral adjustment of the frame to vary its width, screws provided with gear-wheels and having a connection with the movable

members of the frame so as to adjust the same laterally, shafts located at opposite ends of the frame and each provided with shiftable gear-wheels adapted to be brought into and out of engagement with the gear-wheels on the adjusting-screws, means connecting the said end shafts with each other so that motion may be transmitted from one to the other, and mechanism for rotating the shafts, substantially as and for the purposes described.

5. In a burial device, the frame composed of the adjustable side members and end members, screw-shafts for adjusting the side members and provided with gear-wheels, rotatable shafts located at opposite sides of the frame and provided with spools carrying straps adapted to be wound upon and unwound from the spools by the rotation of said shafts, a transverse rotatable shaft geared with said side shafts, movable gears on said side shafts adapted to be moved into and out of engagement with the gears on the screw-shafts, and means for rotating the transverse end shaft so as to transmit motion to the side shafts, substantially as and for the purposes described.

6. In a burial device, the combination of the frame provided with rotatable shafts carrying spools, straps or bands secured to said spools so as to be wound upon and unwound therefrom, said straps being secured at one end to the spools and formed with a separable intermediate strap-section, the meeting ends of the straps being provided one with hooks and the other with eyes to permit the connection and separation of the parts of the straps, said eyes being formed of tips with cut-out portions and a rod passed transversely across the cut-out portions, substantially as and for the purposes described.

7. In a burial device, the combination with the frame, of rollers suspended between the opposite sides of the frame, hangers secured to one side of the frame and having one end of the rollers secured thereto to permit rotation of the rollers and swinging of the same when released at one end, and journal-pins located at the opposite side of the frame and adapted to be inserted and withdrawn from the ends of the rollers so as to support the rotatable rollers and when retracted release the rollers, substantially as and for the purposes described.

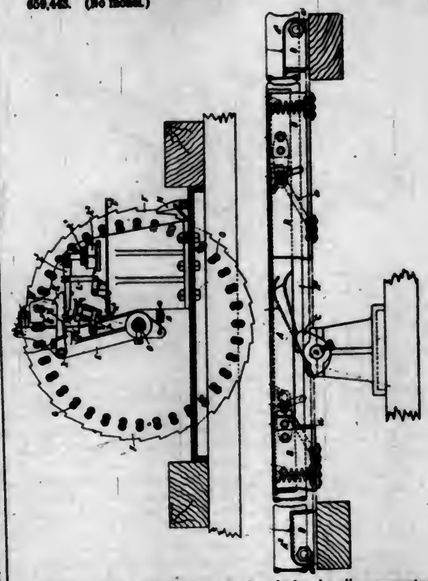
8. In a burial device, the combination with the frame, of rollers supported between the opposite sides of the frame, said rollers being formed in telescopic sections and provided with means for securing the sections at their adjustment, substantially as and for the purposes described.

9. In a burial device, the combination with the frame, of the rollers supported between opposite sides of the frame, said rollers being formed in telescopic sections, one section having a screw extending therefrom into the other section, a nut in said section to receive the screw, and means for locking the screw to its adjustment, substantially as and for the purposes described.

10. In a burial device, the combination of the frame laterally adjustable to vary its width, supporting-wheels for the frame, pivoted tongues extending in front of one set of wheels and provided with brake-shoes to bear against the wheels to steady the frame, and a handle connecting the opposite tongues and permitting the adjustment of the tongues thereon to correspond with the width adjustment of the frame, substantially as and for the purposes described.

11. In a burial device, the combination of the frame for supporting the casket, wheels supporting the frame, the tongues hinged at one end to a portion of the frame of the wheels, a handle having a hinged connection with the tongues so as to move the casket-supporting frame, and means for limiting the movements of the handle both vertically and horizontally, substantially as and for the purposes described.

12. In a burial device, the combination with the frame, of the mantle formed with an outer and an inner curtain adapted to lie respectively to the outside and the inside of the frame and formed in sections so as to be adjustable to vary the dimensions thereof, substantially as and for the purposes described.



13. In a burial device, the combination with the frame, of the mantle enveloping the frame and having an inside curtain, and swinging arms adapted to contact with the inside curtain and when raised to elevate the inside curtain and form a canopy over the space inside of the frame, substantially as and for the purposes described.

14. In a burial device, the combination with the frame, of the curtain, the rotatable shafts, the arms attached thereto, means to rotate said shafts to elevate said arms, and means for holding the arms in their elevated position, substantially as and for the purposes described.

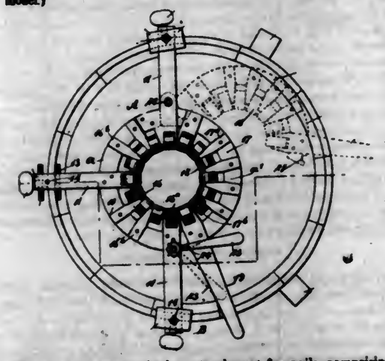
15. In a burial device, the combination with the casket-supporting frame and its supporting-wheels, of the track-rails adapted to lie on opposite sides of a grave and receive said wheels to support the burial device over the grave, and means attached to the rails for suspending a curtain inside the grave, substantially as and for the purposes described.

605,861. FOG SIGNALING APPARATUS FOR RAILWAYS.

HERBERT TOMLINS, London, England, assignor to the Electric Fog-Signal Syndicate, Limited, same place. Filed Nov. 22, 1897. Serial No. 659,443. (No model.)

Claim.—1. In the herein-described explosive signaling apparatus, a revolving cartridge holding disk having pairs of cartridge-holding chambers or barrels arranged in a circle, the two members or barrels of each pair being on the same radius, in combination with a breech-block common to the two chambers or barrels, and hinged to swing ontward toward the circumference when opened, firing-pins for the two barrels yoked together, and a firing-hammer adapted to act on both firing-pins substantially as specified.

2. In the herein-described explosive signaling mechanism the combination, with a revolving cartridge-holding disk provided with breech-closing and firing mechanisms as described, of a spring-projected retractable wiper for acting on the firing-hammer as described, the wiper being carried by an arm on a treadle-operated rock-shaft, an electromagnet whereof the armature is connected to the wiper so as, when attracted, to retract the wiper from operative position, a switch connected to the signal-operating mechanism so as to close the circuit of the electromagnet when the signal is moved to "all right," and of retaining mechanism consisting of a lever-bolt caused to engage the wiper and retain it in the retracted inoperative position until, by the oscillation of the rock-shaft by the depression of the treadle, the lever-bolt is tripped by contact with a fixed abutment and the wiper is permitted to resume its operative position in readiness for acting when next the signal is put to "danger" substantially as specified.



3. In the herein-described explosive signaling apparatus the combination with a revolving cartridge-holding disk, of a gravity or spring operated pawl-arm, engaging with the disk so as to give step-by-step motion thereto, and fast on a rock-shaft provided with another arm adapted when raised to be acted on by a wheel-depressed treadle, retaining mechanism consisting of a latch-lever engaging with a catch for preventing the action of the lever, and of electromagnetic releasing mechanism for disengaging the latch on the closure of the magnet-circuit by a switch operated by the movement of the signal to "danger" so that when the pawl-arm is thus permitted to act, the cartridge-carrying disk will be partially rotated to bring the next chamber to firing position and raise the other arm on the rock-shaft into position to be acted on by the depression of the treadle as specified.

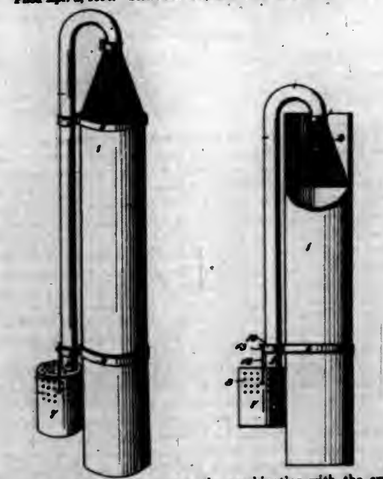
4. In the herein-described explosive signaling mechanism, the combination with a revolving disk having cartridge-holding chambers provided with breech-closing blocks, fire-pins and a spring-actuated hammer pivoted in position to act on the firing mechanism which is in firing position, of a radial wiper mounted on a rock-shaft concentric with the cartridge-disk so as to swing through an arc by the rocking motion of the shaft, the wiper being mounted adjustably in such position that it may either be projected so as to act on the said fire-hammer, or be retracted so as to pass clear of the hammer without acting on it, according as the fog-signal is or is not to be fired, as specified.

5. In the herein-described explosive signaling mechanism, the combination with each breech mechanism having its own firing-hammer, of an indicator consisting of a spring-plate pivoted to the breech-block in position to be swung beneath the fire-hammer of the mechanism to which it pertains, a spring tending to swing such indicator-plate from beneath the hammer, and a lip on the indicator-plate adapted to be swung into locking engagement with the said hammer and to be released therefrom by the cocking of said hammer, substantially as specified.

605,862. MOP-WRINGING ATTACHMENT FOR PAILS.

FRANK TRIBBLE, Greensburg, Ind. Filed Feb. 3, 1896. Serial No. 663,922. (No model.)

Claim.—1. A mop-wringing attachment for pails, comprising a section arranged for attachment to a pail, and a pivotal section, both sections being provided with rollers at their inner edges, and means for locking the two sections together, for the purpose specified.



2. A mop-wringing attachment for pails and like receptacles, consisting of pivotally-connected semicircular sections, a locking device for the two sections, rollers located at the inner edges of the sections, and arms projected from one of the sections, provided with clamps, for the purpose specified.

3. A mop-wringing attachment for pails and like vessels, consisting of two segmental pivotally-connected sections, both sections being provided at their inner edges with rollers, one section having arms projected therefrom and clamps attached to the said arms, the other section being provided with a handle whereby it may be readily opened from the opposing section, for the purpose specified.

4. A mop-wringing attachment for pails and like receptacles, consisting of pivotally-connected segmental sections, rollers held to revolve at the inner edges of the said sections, arms projected from one of the said sections, clamps adjustable upon said arms, a handle projected from the opposing section, each section being provided with recesses adapted to register, and a lock-lever pivoted upon one section and provided with a member arranged to enter the recesses of the two sections when said recesses are brought in registry, as specified.

605,868. SPARK-ARRESTER.

JAMES W. TROUTT, Elkton, Ky. Filed Apr. 2, 1897. Serial No. 630,363. (No model.)

Claim.—In a spark-arrester, the combination with the smoke-stack, of a conical sieve, a deflector arranged at or near the top thereof, a pipe leading from the reduced end of said sieve downward along and in parallel relation to the stack, a metallic band extending around the stack adjacent to the discharge end of said pipe and having a portion which embraces the pipe for supporting the latter, and also provided with an upwardly-pointed hook, and a perforated water-receptacle having an opening in its upper end to receive the discharge end of said pipe, and also provided with a bail to be received upon the hook of the band, substantially as described.

605,864. BOOKBINDING.

JOSHUA R. WALES, Marlborough, Mass. Filed Oct. 2, 1897. Serial No. 653,882. (No model.)

Claim.—The combination, with the body of a book and the covers proper, of the back-binding, composed of the strip of fabric having transversely-separated portions or tongues, 4 and 5, which are secured on the covers and body, respectively, and the tapes 7, which are arranged within such binding, and passed through longitudinal slits in the tongues 4, and glued down on such tongues, as shown and described.

605,865. BICYCLE.

ALBERT S. WEAVER, Hamilton, Canada. Filed Sept. 9, 1896. Serial No. 605,281. (No model.)

Claim.—1. A bicycle provided with a front frame extending transversely and having side arms and top and bottom cross-arms connecting the side arms, a center brace located between and parallel with the side arms and connecting the top and bottom cross-arms, a brace connecting the said center brace with the upper part of the

steering-head for the front wheel, braces connecting the said steering-head with the bottom cross-arm at each side of the said center brace, and a saddle and a pedaling device carried at each side of the said frame substantially as shown and described.

2. In a bicycle, the combination with a front frame extending transversely and provided with side arms and top and bottom cross-arms, a center brace connecting the said top and bottom cross-arms, and a brace connecting said center brace with the steering-head of the front wheel to leave the side of the frame open at the front on both sides of the said brace, of a rear frame extending transversely and adapted to carry the rear or drive wheel, a longitudinally-extending brace connecting the middle portion of the top of the rear frame with the middle portion of the top of the front frame, and braces connecting the lower portions of the sides of the front and rear frames with each other, whereby an open space is left between the sides of the front and rear frames, the sides of the front and rear frames being arranged to carry saddles and pedaling devices, substantially as shown and described.

3. In a bicycle, a frame comprising a transversely-extending front frame adapted to carry saddles and pedaling devices, the said front frame being provided with side arms and top and bottom cross-arms connecting the side arms, a center brace connecting the top and bottom cross-arms, a steering-head for the front wheel, a brace connecting the upper part of the steering-head with the said center brace, braces connecting the lower part of the steering-head with the bottom cross-arm of the frame at each side of the center brace, and a transversely-extending rear frame connected with the front frame and arranged to carry the rear wheel and also arranged to carry saddles and pedaling devices, substantially as shown and described.

4. In a bicycle, a transversely-extending front frame adapted to carry saddle and pedaling devices and having side arms connected by top and bottom cross-arms, a center brace connecting the top and bottom cross-arms, a steering-head provided with forks for the front wheel, a cross-arm held on the upper end of the steering-head and provided at each end with a head for the handle-bars, a brace connecting the upper part of the steering-head with the said center brace, braces connecting the lower part of the steering-head with the bottom cross-arm of the frame at each side of the center brace, and a transversely-extending rear frame connected with the front frame and arranged to carry the rear wheel and also arranged to carry saddles and pedaling devices, substantially as shown and described.

5. A bicycle, comprising a transversely-extending front frame having side arms connected by top and bottom cross-arms, a center brace connecting the top and bottom cross-arms a steering-head provided with forks for the front wheel, a brace connecting the upper part of the steering-head with the said center brace, a lower brace connecting the said steering-head with the bottom cross-arm, a transversely-extending rear frame connected with the front frame and carrying the rear or drive wheel, saddles and pedaling devices carried by each side of the front and the rear frame, and steering devices for the said front fork, substantially as shown and described.

6. In a bicycle, a transversely-extending front frame having side arms connected by top and bottom cross-arms, a center brace connecting the top and bottom cross-arms, a steering-head provided with forks for the front wheel, a brace connecting the upper part of the steering-head with the said center brace, a lower brace connecting the said steering-head with the bottom cross-arm of the front frame, a transversely-extending rear frame connected with the front frame and carrying the rear or drive wheel, saddles and pedaling devices carried by each side of the front and the rear frame, a handle-bar for each of the saddles, and steering devices for the front fork, substantially as shown and described.

7. A bicycle-frame comprising a transversely-extending front frame provided with side arms and a top and bottom cross-arm, a center brace connecting the top and bottom cross-arms, a steering-head for the front fork, inclined braces connecting the said steering-head with the bottom cross-bar at each side of the said center brace, a brace connecting the upper end of the steering-head with the center brace of the said front frame, a transversely-extending rear frame connected by longitudinally-extending braces with the front frame and comprising side arms and a cross-arm connecting the side arms, the said rear frame having a rearward extension at each side in which the rear wheel of the bicycle is adapted to be journaled, the sides of the front and the rear frame being arranged to carry saddles and pedaling devices, substantially as shown and described.

8. A bicycle, comprising a transversely-extending front frame carrying saddles and pedaling devices at its sides, a transversely-extending rear frame carrying the rear wheel of the bicycle and likewise carrying saddles and pedaling devices at its sides, a central longitudinally-extending brace connecting the upper parts of the front and the rear frames, braces connecting the sides of the said front and rear frames near the bottoms thereof, arms extending rearwardly from each side of the front frame and carrying the rear handle-bars, a steering-head in which the fork of the front wheel is mounted, a rearwardly-extending brace connecting the said steering-head with the front frame, and a cross-arm held on the upper end of the steering-head and provided at each end with a head for the front handle-bars, substantially as shown and described.

9. A bicycle, comprising a transversely-extending front frame carrying saddles and pedaling devices at its sides, a transversely-extending rear frame carrying the rear wheel of the bicycle and also carrying saddles and pedaling devices at its sides, a central longitudinally-extending brace connecting the top portions of the front frame with the top portion of the rear frame, longitudinally-extending braces connecting the side of the said front and rear frames, at the lower portion thereof, horizontally-arranged arms extending rearwardly from the sides of the front frame and carrying the rear handle-bars, a steering-head in which the fork of the front wheel is mounted, a brace connecting the said steering-head with the front frame, a cross-arm held on the upper end of the steering-head and provided at each end with a head for the front handle-bars, and a connection between the stems of the front handle-bars and the front fork for steering the bicycle, substantially as shown and described.

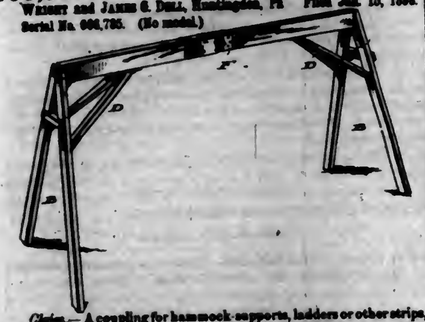
10. In a bicycle, a frame frame comprising side arms connected by a top and a bottom cross-arm, a center brace connecting the said top and bottom cross-arms, the said side arms being arranged to carry saddles at their upper ends, and pedaling devices near their lower ends, a rear frame having side arms connected by a top cross-arm, the said rear frame being likewise arranged to carry saddles and pedaling devices at the sides, a central longitudinally-extending brace connecting the top cross-arm of the rear frame with the top cross-arm of the front frame, lower braces attached to the bosses carrying the pedal-shafts and connecting the side arms of the front and rear frames, longitudinal bottom braces connecting the extreme lower ends of the side arms of the front and rear frames with each other, the extreme rear ends of the said bottom braces extending upwardly and rearwardly to connect with rear lower braces extending rearwardly from the bosses of the pedal-shafts of the rear frame, the rear ends of the said rear lower braces being arranged to carry the rear wheel of the bicycle, upper rear braces connecting the rear ends of the said lower rear braces with the upper ends of the side arms of the rear frame, arms extending rearwardly from the upper part of the side arms of the front frame and adapted to carry the rear handle-bars, a steering-head for the fork of the front wheel, rearwardly-extending braces connecting the lower part of said steering-head with the lower cross-arm of the front frame, a brace connecting the upper part of the steering-head with the center brace of the front frame, and a cross-arm held on the upper end of the steering-head and provided at each end with a head for the front handle-bars substantially as shown and described.

605,866. BARRICADE-ALARM FOR DOORS. GEORGE D. WILTSEE, Reno, Nev. Filed Jan. 21, 1898. Serial No. 667,456. (No model.)

Claim.—1. A barricade-alarm for doors comprising a strut-bar having at its upper end a sliding connection with the door and an alarm mechanism supported on the door and including a trip-bar arranged for operation by the upper end of the strut-bar substantially as set forth.

2. A barricade-alarm for doors, comprising an alarm mechanism adapted to sound the alarm repeatedly and having a trip-bar adapted to release the alarm and a catch or detent for holding said bar when adjusted to release the alarm and a strut-bar for operating the trip-bar substantially as set forth.

3. In an apparatus substantially as described the combination of the door, a strut-bar having at its upper end a sliding connection with said door and the alarm supported independently of the strut-bar and having a trip portion arranged to be released by said strut-bar substantially as described.



4. A barricade-alarm for doors comprising a frame-plate supporting the alarm mechanism and provided with brackets, a strut-bar having a longitudinally-elongated slot and fitted between said brackets, the pin or bolt passed through said slot whereby the strut-bar has a sliding connection with the frame-plate, and the alarm mechanism having a trip portion arranged for operation by the strut-bar substantially as described.

5. A barricade-alarm for doors comprising the bell, the spring for sounding the bell, the detent-pawl for restraining said spring, the trip-bar arranged at one end to release said detent-pawl, the strut-bar for operating said trip-bar to release the detent-pawl, and a detent for holding said trip-bar when adjusted by the strut-bar substantially as set forth.

6. In an alarm mechanism the combination of the strut-bar having at its upper end a sliding connection with the door, alarm mechanism arranged to be released by such upper end of the strut-bar, and a seat-plate to receive the lower end of the strut-bar substantially as set forth.

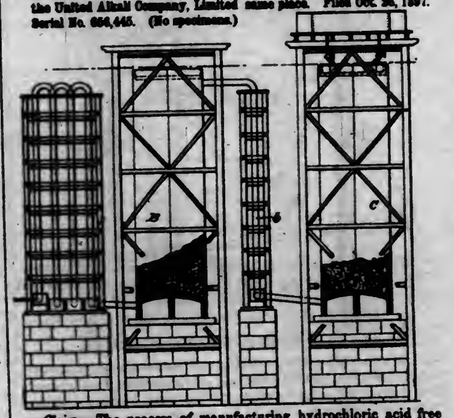
7. A barricade-alarm for doors, comprising the door, the strut-bar, the alarm mechanism arranged for operation by the strut-bar, a seat-plate in the floor, an eye or staple on the door and a bolt at the swinging end of the strut bar arranged to engage the seat-plate when the strut-bar is lowered and the eye or staple when the strut-bar is raised substantially as set forth.

605,867. COUPLING FOR HAMMOCK-SUPPORTS. WILLIAM H. WRIGHT and JAMES G. DELL, Huntingdon, Pa. Filed Jan. 15, 1898. Serial No. 666,795. (No model.)

Claim.—A coupling for hammock-supports, ladders or other strips, consisting of the two sections hinged together the notched plates fastened to the sides of the sections, the plates and loops passing through the same and secured to the sections, and the two interlocking spring-strips on the upper edges of the said sections, as shown and described.

605,868. CROSSCUT-SAW. RUDOLF WIESELER, Chicago, Ill. Filed Aug. 5, 1897. Serial No. 647,288. (No model.)

Claim.—1. In a crosscut-saw, the combination of a saw-blade rigidly attached to a handle, an opposing saw-blade pivotally attached to said handle, and a spring pressing upon said pivoted blade.



2. In a crosscut-saw, the combination of a crescentic saw blade attached to a handle, an opposing segmental saw-blade pivotally attached to said handle, and a spring pressing upon said pivoted blade.

3. In a crosscut-saw, the combination of a crescentic saw-blade attached to a handle, an opposing segmental saw-blade pivotally attached to said handle, a spring pressing upon the pivoted blade, and means for determining the tension of said spring.

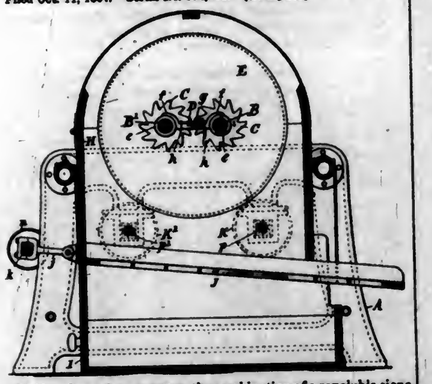
4. In a crosscut-saw, the combination of a crescentic saw-blade attached to a handle, an opposing segmental saw-blade pivoted to said handle, a spring pressing upon said pivoted blade, a gear-wheel to the hub of which the heel end of said spring is attached, an idle-wheel engaging with said gear-wheel, a crank-handle for turning the pinion, a ratchet-wheel on the pinion-shaft and a pawl upon the handle, which engages with the ratchet-wheel.

5. In a crosscut-saw, the combination of a handle carrying ratchet and gear wheels, a spring controlled by said wheels, crescentic and segmental blades adapted to encircle a tree, and one of which is pivoted and pressed upon by said spring and a flat chain rest or support, as and for the purpose described.

605,869. PROCESS OF MAKING HYDROCHLORIC ACID. JOHAN R. WYLDE and JOHAN W. KYNASTON, Liverpool, England, assignors to the United Alkali Company, Limited same place. Filed Oct. 26, 1897. Serial No. 656,445. (No specimens.)

Claim.—The process of manufacturing hydrochloric acid free from arsenic from gases evolved by the treatment of an alkaline chlorid with ordinary arsenical sulfuric acid or the gases known as "roaster-gas," or the gases evolved during the calcination of a mixture of bisulfate of soda with common salt, consisting in first cooling the said gases, and then passing them in the presence of chlorin through or in contact with coke, in a "dry tower" in which the arsenic is retained, and thence to a wet tower, in which the hydrochloric acid is condensed, substantially as hereinbefore described.

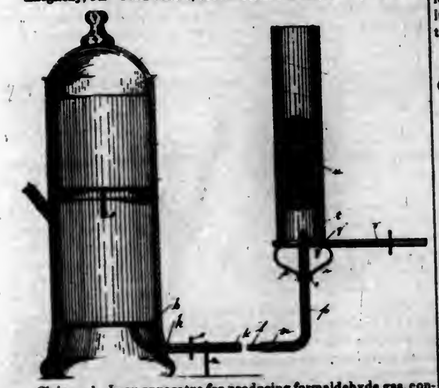
605,870. TRESTLE. HARRY L. ADAMS, Wilmington, Vt. Filed Sept. 20, 1897. Serial No. 653,239. (No model.)



Claim.—1. A saw-bench consisting of a top, legs hinged thereto having a four-way movement, a toggle-joint interposed between each pair of legs, a brace-rod connected at one end to the joint and means for engaging the rod in position for holding the joint in the open or folded position of the legs, substantially as described.

2. In combination, a top, two pairs of legs hinged thereto so as to have a four-way motion; a toggle-joint interposed between each pair of legs, a brace-rod pivoted to the center of each of the toggle-joints, and a guide-strip having a slot formed therein through which the inner end of said brace-rod passes and is adapted to slide, as specified.

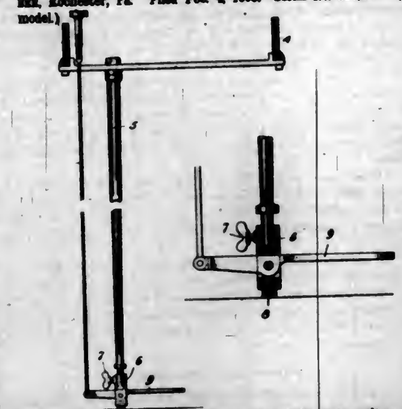
3. The herein-described combination of the top A, the legs B hinged thereto so as to have a four-way motion, clips G swiveled to said legs, a toggle-joint, the members of which are pivoted to the clips and to each other, a brace-rod K having its outer end bifurcated and pivoted to the center of the toggle-joint, a guide-strip secured to the under side of the top and having a slot formed therein, said slot terminating at each end in an enlargement, and a reduced end L formed with the brace-rod adapted to run within said groove and be locked in one of said enlargements, substantially as and for the purpose set forth.



4. In combination with a saw-bench of the character described, hinged legs, toggle-levers for forcing said legs apart, a brace-rod connected to the levers, an angle-iron through which the outer end of said rod passes, said iron having a slot and locking-notches formed therein, a cam-lever pivoted upon the end of the brace-rod, and a cam formed with said lever adapted to force this end of the brace-rod into the locking-notches, and a spring adapted to hold the cam-lever in its locked position, as specified.

605,371. TOBACCO-CUTTER. JOHN B. ADT, Baltimore, Md. Filed Oct. 11, 1897. Serial No. 654,773. (No model.)

Claim.—In a tobacco-cutter, the combination of a revoluble sieve, a pair of revoluble shafts within the sieve, saws on the said shafts, spacing-collars between the saws, and removable bridge cutters of a width corresponding with that of the spacing-collars situated between the saws with their ends resting on and supported by the said spacing-collars, substantially as specified.



605,372. FORMALDEHYDE-GENERATOR. OSCAR I. AFFELDER, Allegheny, Pa. Filed June 1, 1897. Serial No. 639,064. (No model.)

Claim.—1. In an apparatus for producing formaldehyde gas, consisting of a tank having two compartments, the upper tank receiving and supplying the lower tank with alcohol, a pipe connected to the lower tank and carrying a wick at its free end, a burner surrounding said free end of the pipe, and connected thereto by means of braces, a gas-supply connected to said burner, supports projecting inwardly from said burner, a metallic chimney engaging said supports, so that the flame acts upon the outside of said chimney and having a foraminous mantle arranged thereto, said chimney producing a draft so that the vaporized alcohol will come in contact with the mantle or casing, whereby formaldehyde gas will be generated and will pass out through the top of the chimney, substantially as shown and described.

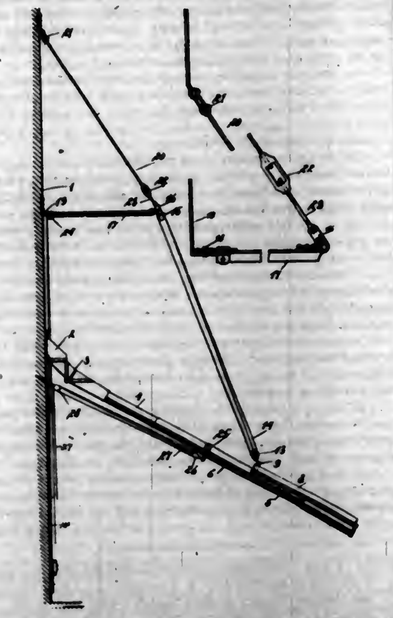
2. In an apparatus for generating formaldehyde gas, consisting of a tank having two compartments, a discharge-pipe leading from the lower compartment and carrying a wick in the discharge and a burner having suitable connections with a gas-supply, said burner surrounding the end of the discharge-pipe and connected thereto, a metallic chimney supported within said burner so that the flame acts upon the outside thereof and having a foraminous mantle arranged therein, said chimney producing a draft so that the vaporized alcohol will come in contact with said foraminous casing or mantle, whereby formaldehyde gas will be generated and pass out through the chimney, substantially as shown and described.

605,373. TYPE-WRITER ATTACHMENT. FREDERICK G. BARBER, Rochester, Pa. Filed Feb. 4, 1895. Serial No. 537,156. (No model.)

Claim.—1. In a platen-shifting attachment for type-writers, the combination with a shifting mechanism, of a foot-lever arranged to receive the toe portion of the foot beneath it and to shift the platen by an upward lift.

2. The combination with a shifting device for a type-writer, of a foot-lever arranged to receive the forward part of the foot beneath its projecting end, the other end of the lever having a direct link connection to the shifting device so that an upward lift of the foot will shift the platen.

3. The combination with a shifting device for a type-writer, of a foot-lever arranged to receive the toe portion of the foot beneath its projecting end, an adjustable fulcrum for said lever, and a connection between the lever and the shifting device.



605,374. TRACE-HOLDER. GRANVILLE BARTLETT, Lexington, Ky. Filed Nov. 27, 1897. Serial No. 659,947. (No model.)

Claim.—1. A trace-holder consisting of a single piece of wire having its middle portion constructed in the form of a helical spring forming a shank, and having at one end of said spring two attaching-eyes one on either side, and at the other end a hook with a prolonged beak formed of the wire doubled on itself and having its free end turned back and housed within the helix substantially as and for the purpose described.

2. The combination with a singletree having a vertical hole through its end; of a trace-holder consisting of a helical spring with attaching-eyes at one end, and a hook at the other whose beak is made double with the free end of the wire extended into the coil of the spring, said beak being extended vertically past the level of the coil or shank portion and adapted to pass through the hole in the singletree substantially as and for the purpose described.

605,375. GRAIN-SPOUT. ALBERT D. BELLINGER, West Superior, Wis. Filed Nov. 29, 1897. (Serial No. 660,053. (No model.)

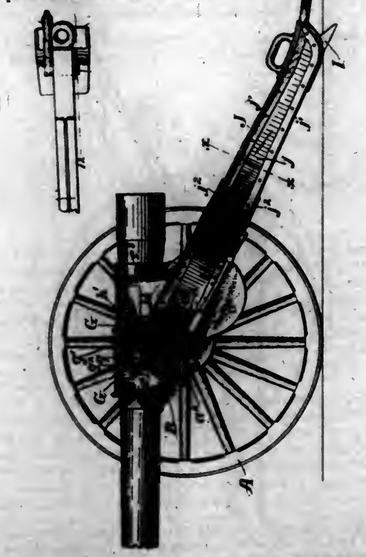
Claim.—1. A grain-spout, comprising two telescopic sections, one of said sections being longitudinally slotted at the top and adapted to slide on the other section, an arm extended from the lower end of the upper section through said slot, means for raising and lowering the spout, and means for moving the movable section on the other section, substantially as specified.

2. A grain-spout, comprising a section having a hinged connection with an elevator-wall, a lower section having an extension engaging around the first-named section, the said lower section being longitudinally slotted, plates extended upward at opposite sides of the slot, an arm extended from the hinged section and extended through the slot, a lifting-rope having connection with said arm and a draw-rope having connection with the extension of the slotted section, whereby said slotted section may be moved longitudinally of the hinged section.

605,376. GUN-CARRIAGE. WILLIAM H. BEVANS, Washington, D. C. Filed Sept. 23, 1897. Serial No. 652,757. (No model.)

Claim.—1. The combination of a gun, a fluid recoil-check located beneath and in close proximity to said gun, said gun directly actuating the mechanism of said recoil-check, said recoil-check being provided with a cylinder arranged substantially at right angles to the axis of the gun, substantially as described.

2. The combination of a gun, a fluid recoil-check located beneath and in close proximity to said gun, said recoil-check being provided with a rotatable cylinder arranged at substantially right angles to the axis of the gun, substantially as described.



3. The combination of a gun, a fluid recoil-check having a cylinder arranged substantially at right angles to the axis of the gun, and means for transmitting the recoil of the gun to said check, causing said cylinder to rotate partially, substantially as described.

4. The combination of a gun, a fluid recoil-check provided with a cylinder located at substantially right angles to the axis of the gun, means for transmitting the recoil of the gun to said cylinder, causing the latter to rotate partially, and means for restoring the gun to its normal position, substantially as described.

5. The combination of a gun, a fluid recoil-check provided with a cylinder located substantially at right angles to the axis of the gun, and a stationary piston in said cylinder, substantially as described.

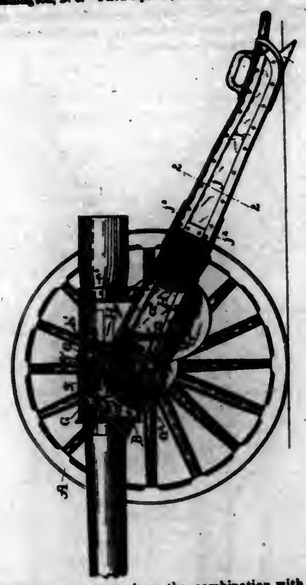
6. The combination of a gun, a recoil-check provided with a rotatable cylinder located at substantially right angles to the gun, a stationary piston in said cylinder, and means for rotating said cylinder by the recoil of the gun, substantially as described.

7. The combination of a gun, a recoil-check provided with a rotatable cylinder arranged at substantially right angles to the gun, a stationary piston in said cylinder, means for rotating said cylinder by the recoil of the gun, and means for restoring said gun to its normal position, substantially as described.

8. The combination with a gun, of a casing in which said gun is mounted and adapted to slide, a recoil-cylinder journaled in said casing at right angles to the gun, and means for transmitting the recoil of the gun to said cylinder, substantially as described.

9. The combination with a gun, of a casing in which said gun is mounted and adapted to slide, a recoil-cylinder journaled in said casing and provided with teeth upon its periphery, and a rack secured to said gun and adapted to engage with the teeth on said cylinder, so that the recoil of said gun will tend to rotate the cylinder, substantially as described.

10. The combination with a gun, of a casing in which said gun is mounted and adapted to slide, a recoil-cylinder journaled in said casing and provided with teeth on its periphery, a stationary piston in said cylinder, a rack secured to said gun and meshing with the teeth on said cylinder and means for restoring the gun to its normal position after firing, substantially as described.



11. The combination with a gun, of a casing in which said gun is mounted and adapted to slide, a recoil-cylinder journaled in said casing and provided with teeth on its periphery, said cylinder being provided with a groove in its inner surface, a stationary piston in said cylinder, a rack secured to said gun and engaging the teeth on said cylinder, and a ring shrunk onto the gun to which said rack is fastened, substantially as described.

12. The combination with a gun, of a casing in which said gun is mounted and adapted to slide, a recoil-cylinder journaled in said casing, means for transmitting the recoil of the gun to the said cylinder to cause the latter to rotate and spiral springs connected to said cylinder and said casing to restore the gun to its normal position after firing, substantially as described.

13. Recoil mechanism for guns, consisting of a stationary piston and shaft having screw-threaded and enlarged portions supporting said piston, supports for said shaft, a cylinder provided with gear-teeth on a part of its periphery inclosing said piston, stops in the interior of said cylinder to limit its motion, said cylinder also being provided with a groove of varying area on its inner surface and the ends of said cylinder being provided with a circular groove, with which extensions on the piston engage, substantially as described.

14. A casing for a gun, having the upper part made substantially circular in shape and provided with two grooves, one for the reception of an enlarged part of the gun and the other for the reception of a rack attached to said gun, projections on said casing adapted to receive a shaft for elevating and depressing said gun, said casing being also provided with journals, for the reception of the main axle and for the reception of the shaft of the recoil mechanism, substantially as described.

605,877. FIELD-MOUNT FOR ARTILLERY. WILLIAM H. BEVANS, Washington, D. C. Filed Apr. 19, 1898. Serial No. 678,144. (No model.)

Claim.—1. In a gun-carriage the combination with a casing mounted upon the axle of the carriage and carrying the gun, and a shaft provided with gearing mounted in the said casing, of a trail also mounted on the said axle, a flask on the said trail, teeth on the said flask meshing with the gearing on the casing, and ratchet mechanism for operating the said gearing, substantially as described.

2. In a gun-carriage the combination with a casing mounted upon the axle of the carriage and carrying the gun, bearings on the said casing, a shaft mounted in the said bearings, and a worm-gear on the said shaft; of a trail also mounted on the said axle, a flask on the said trail, teeth on the said flask to mesh with the gearing on the casing, and ratchet mechanism for operating the said gearing, substantially as described.

3. In a gun-carriage the combination with a casing mounted upon the axle of the carriage and carrying the gun, extensions on the said casing having bearings therein, a shaft mounted in the said bearings, a worm-gear on the said shaft, a spring located between one of the extensions and the worm-gear; of a trail also mounted on the said axle, a flask on the said trail, teeth on the said flask to mesh with the gearing on the casing, and ratchet mechanism for operating the said gearing, substantially as described.

4. The combination with the axle of a gun-carriage having screw-threads thereon, of a ratchet-gear correspondingly screw-threaded engaging the said screw-threads, and provided with teeth, a casing surrounding the said gear and prolonged into a hollow handle, a rod in the said hollow handle, a pointed end on the said rod within the said handle to engage the said ratchet-teeth and means for normally keeping the end of said rod out of engagement with said ratchet-teeth, substantially as described.

5. The combination with the axle of a gun-carriage having screw-threads thereon, of a ratchet-gear correspondingly screw-threaded engaging the said screw-threads, and provided with teeth, a casing surrounding the said gear and prolonged into a hollow handle, a rod in the said hollow handle, a pointed end on the said rod within the said handle to engage the said ratchet-teeth, a spring in the said handle to normally keep the end of said rod out of engagement with the said ratchet-teeth, and a lever for operating the said rod to bring the pointed end thereof into engagement with the said ratchet-teeth, substantially as described.

6. Means for training a gun in a horizontal plane, consisting of screw-threads on the axle of the carriage, a wheel correspondingly threaded to engage the said screw-threads, and means to operate the latter whereby by operating the gearing the carriage will be swung around the spade as a center, substantially as described.

7. Means for training a gun in a horizontal plane consisting of screw-threads on the axle thereof a ratchet-gear correspondingly threaded and meshing with the said threads on the axle, and a ratchet and pawl for operating said ratchet-gear, substantially as described.

8. Means for training a gun in a horizontal plane consisting of a relatively-fixed spade resting upon the ground, gearing upon the said spade, gearing upon the trail meshing with the said gearing on the spade, and means for operating the latter, whereby the trail will be moved along upon the spade, substantially as described.

9. Means for training a gun in a horizontal plane consisting of a relatively-fixed spade resting upon the ground, worm-teeth upon the said spade, a worm-gear mounted in the trail and meshing with the teeth upon the spade and a ratchet and pawl for operating the said worm-gear, substantially as described.

10. Means for training a gun in a horizontal plane consisting of screw-threads on the axle of the carriage, a wheel engaging the said screw-threads, and means for turning the said wheel to cause the carriage to slide upon the axle, and a spade resting upon the ground, gearing on the said spade, gearing on the trail meshing with the gearing on the spade and means for turning the latter to cause the trail to swing around upon the spade, substantially as described.

11. A trail for a gun-carriage, the upper part of which is horse-shoe-shaped and the part which is supported by the axle curved substantially into the arc of a circle around the center of which the gun is moved when it is elevated or depressed, and the lower part consisting of one member shaped like an I-beam and attached to the center of the upper part, triangular plates fastened above and below the junction of the two parts and a foot attached to said lower part, substantially as described.

12. In a gun-carriage the combination with a trail and gearing upon the said trail, of a relatively-fixed spade resting upon the ground, gearing upon the said spade meshing with the gearing upon the trail to move the trail upon the spade, substantially as described.

13. In a gun-carriage the combination with a trail and a worm-gear upon the said trail, of a relatively-fixed spade resting upon the ground, teeth on the said spade meshing with the said worm-gear to swing the trail around upon the spade, substantially as described.

605,878. PROCESS OF MAKING ALUMINIUM SULFID. HENRY S. BLACKMORE, Mount Vernon, N. Y., assignor to the Pure Aluminium and Chemical Company, of West Virginia. Filed June 12, 1896. Renewed Apr. 21, 1898. Serial No. 678,481. (No specimens.)

Claim.—1. The process for transforming aluminium oxid into aluminium sulfid which consists in simultaneously conveying into a chemically inert molten bath capable of dissolving aluminium sulfid, a mixture of aluminium oxid and carbon bisulfid substantially as described.

2. The process for transforming aluminium oxid into aluminium sulfid which consists in introducing simultaneously heated aluminium oxid and carbon bisulfid into a molten bath capable of dissolving the aluminium sulfid produced, without reacting or decomposing either the materials introduced or product produced, substantially as described.

3. The process for transforming aluminium oxid into aluminium sulfid which consists in blowing a heated mixture of aluminium oxid and carbon bisulfid into a retort containing a molten bath capable of dissolving the aluminium sulfid produced but not reacting or combining with or decomposing either the aluminium oxid or carbon bisulfid introduced or the aluminium sulfid produced substantially as described.

605,879. RETORT AND METHOD OF MAKING SAME. HENRY S. BLACKMORE, Mount Vernon, N. Y., assignor to the Pure Aluminium and Chemical Company, of West Virginia. Filed June 12, 1896. Renewed Apr. 21, 1898. Serial No. 678,482. (No model.)

Claim.—1. A retort of refractory material such as fire-clay lined with an enamel or glaze of lead sulfid substantially as described.

2. The method of producing an impervious, non-corrodible retort, for manufacture of carbon bisulfid or similar corrosive material, which consists in exposing the inner surface of a retort of refractory material such as fire-clay to the alternate action of lead oxid and carbon-bisulfid vapor or gas while in a heated state substantially as described.

3. A retort, for the manufacture of volatile corrosive materials such as carbon bisulfid, having a lining or coating of lead sulfid substantially as described.

605,880. PROCESS OF PRODUCING ALUMINIUM SULFID AND REDUCING SAME TO METALLIC STATE. HENRY S. BLACKMORE, Mount Vernon, N. Y., assignor to the Pure Aluminium and Chemical Company, of West Virginia. Filed July 22, 1896. Renewed Apr. 21, 1898. Serial No. 678,484. (No specimens.)

Claim.—1. The process of producing aluminium sulfid and reduction of the same to metallic state which consists in simultaneously converting insoluble aluminium oxid into soluble aluminium sulfid while in a molten bath and dissociating the soluble aluminium sulfid by electrolytical action substantially as described.

2. The process of producing aluminium sulfid and reducing the same to metallic state which consists in dissolving aluminium sulfid in a molten bath not capable of dissolving aluminium oxid, and mixing aluminium oxid in the same, then subjecting the mass to electrolytic action whereby the aluminium sulfid is dissociated, metallic aluminium being produced and insoluble aluminium oxid converted into soluble aluminium sulfid by secondary reaction substantially as described.

3. The process of producing aluminium sulfid and reducing the same to metallic state which consists in exposing aluminium oxid to the action of a molten bath of alkali salts capable of dissolving aluminium sulfid, having dissolved therein sulfids-of-alkali bases containing the combined elements of carbon bisulfid and subjecting the same to electrolytic action substantially as described.

4. The process of producing aluminium sulfid and reduction of the same to metallic state which consists in transforming aluminium oxid into aluminium sulfid by action of thiocarbonate-of-alkali bases, then dissociating the sulfid by electrolysis simultaneously producing metallic aluminium at the cathode and thiocarbonate-of-alkali bases at the anode by secondary reaction, and then adding more aluminium oxid and continuing the electrolysis substantially as described.

5. The process of producing aluminium sulfid and reduction of the same to metallic state which consists in supplying aluminium oxid to a molten bath of sulfid-of-alkali bases during process of electrolysis while employing carbon anodes substantially as described.

6. The process of producing aluminium sulfid and reduction of the same to metallic state which consists in introducing aluminium oxid into a molten bath of sulfid-of-alkali bases containing the combined elements of carbon bisulfid, and electrolyzing the aluminium sulfid produced, thus producing metallic aluminium and regenerating the bath with the combined elements of carbon bisulfid substantially as described.

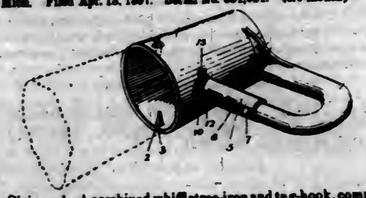
7. The process of producing aluminium sulfid and reduction of the same to metallic state which consists in simultaneously converting aluminium oxid into sulfid by chemical action while suspended in a molten bath of alkali salts, containing sulfid-of-alkali bases and combined elements of carbon bisulfid, and dissociating the sulfid produced by electrolytic action employing carbon anodes substantially as described.

8. The process of producing aluminium sulfid and reduction of the same to metallic state which consists in producing aluminium sulfid in a molten bath of sulfid-of-alkali bases during electrolytic action by adding insoluble aluminium oxid to said bath substantially as described.

9. In the process of producing aluminium sulfid and reduction of the same to metallic state the process for producing aluminium sulfid which consists in transforming aluminium oxid into aluminium sulfid by chemical action of thiocarbonate-of-alkali bases and reduction of aluminium and reproduction of thiocarbonate-of-alkali bases by electrolysis of aluminium sulfid substantially as described.

10. In the process of producing aluminium sulfid and reduction of the same to metallic state, the art of producing aluminium sulfid which consists in introducing aluminium oxid into a molten bath of sulfid-of-alkali bases containing thiocarbonates, and separating the aluminium from the sulfid produced, by electrolysis substantially as described.

11. In the process of producing aluminium sulfid and reduction of the same to metallic state, the process of transforming aluminium oxid into sulfid by chemical action of thiocarbonates, (or sulfid-of-alkali bases containing combined carbon bisulfid) and finally eliminating the metallic aluminium from the product by process of electrolysis substantially as described.



12. In the process of producing aluminium sulfid and reducing the same to metallic state the process of subjecting a molten bath containing dissolved aluminium sulfid to electrolytic action at a temperature sufficient to produce carbon bisulfid at the anode while in a molten bath capable of taking up the combined elements of carbon bisulfid so produced at the temperature employed and suspending aluminium oxid in said bath said bath being maintained at a temperature sufficient to permit reaction substantially as described.

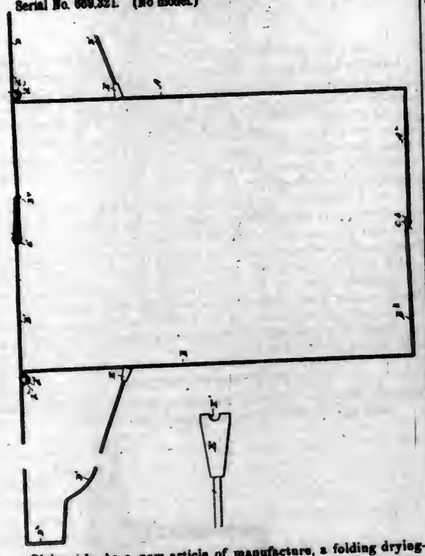
13. In the process of producing aluminium sulfid and reduction of same to metallic state, the art of producing thiocarbonate-of-alkali bases which consists in dissociating aluminium sulfid by electrolysis while dissolved in a molten bath of sulfid-of-alkali bases at a temperature sufficient to produce carbon bisulfid but not so high as to prevent the absorption of the same by the sulfid-of-alkali bases substantially as described.

14. The herein-described process of converting metallic oxid into sulfid and effecting final elimination of metallic base which consists in introducing said oxid into a molten bath containing the thiocarbonate-of-alkali bases and subjecting the product to electrolytic action substantially as described.

15. The process of producing aluminium sulfid herein described which consists in exposing aluminium oxid to the action of thiocarbonate-of-alkali bases in a heated state.

605,881. WHIFFLETREE-HOOK. CALVIN O. BOLTON, Denver, Mich. Filed Apr. 13, 1897. Serial No. 631,921. (No model.)

Claim.—1. A combined whiffletree-iron and tag-hook, comprising a tapering ferrule or sleeve adapted to be secured to the whiffletree, an inturned hook formed integral with said ferrule at its outer end, a thimble movable upon the free end of the hook, said thimble being provided with a beveled outer or rear end and with a longitudinal slot, a pin on the hook passing through said slot in the thimble, and means for holding the thimble normally extended to substantially close the space between the extremity of the hook and the ferrule, substantially as described.

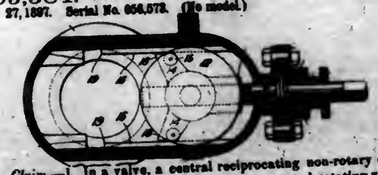


2. A whiffletree-iron and tag-hook, comprising a ferrule adapted to be secured to the whiffletree, a hook formed integral with said ferrule near its outer end, a thimble movable upon the free end of said hook, said thimble having its free end beveled, the ferrule being provided with an opening through which the thimble can be inserted to be positioned upon the hook, a spring for holding the thimble normally extended for substantially closing the space between the end of the hook and the surface of the ferrule, and a hook or projection on the thimble adapting it to be operated by hand for releasing the tug, substantially as described.

605,882. MOTOR. FRANCIS A. BRENNAN, Brockville, Canada. Filed Aug. 14, 1897. Serial No. 648,289. (No model.)

Claim.—1. A motor, comprising a hollow cone, a pitman connecting the apex of said cone with a crank-arm on the main shaft, a cone of a flexible material united at its base with the base of the said hollow cone, a pipe connected with the apex of the said flexible cone to admit and exhaust the motive agent to and from the said cones, the end of the said pipe when the motive agent is admitted extending within the hollow cone to a point near the apex thereof, and a valve mechanism for controlling the admission and exhaust of the motive agent to and from the said pipe, substantially as shown and described.

2. A motor, comprising a hollow cone of rigid or non-flexible material, a pitman extending from the apex of the said cone and connected with a crank-arm on the main shaft, a flexible cone having its base secured to the base of the said non-flexible cone, a fixed pipe rigidly connected with the apex of the said flexible cone to admit and exhaust the motive agent to and from the cones, the end of the said pipe on the return movement of the pitman extending within the non-flexible cone to a point near the apex end, whereby the motive agent admitted exerts its force directly on the apex end of the said cone, and a valve mechanism for controlling the admission and exhaust of the motive agent to and from the said pipe, the said valve mechanism being actuated from the main shaft of the motor, substantially as set forth.



605,388. **FOLDING DRYING-FRAME FOR WOOLEN GARMENTS.** HENRY BRISTOL, New Haven, Conn. Filed Feb. 7, 1898. Serial No. 669,321. (No model.)

Claim.—1. As a new article of manufacture, a folding drying-frame for woolen garments, consisting of two body members and two sleeve members, each of the said members being formed from a single piece of wire, all of the said members being hinged together to permit the frame to be folded, and the sleeve members comprising upper and lower arms, the inner ends of their upper arms being hinged to the upper corners of the body members so as to permit the sleeve members to be folded and unfolded in the planes thereof, and the inner ends of the lower arms of the sleeve members being free but adapted to be engaged with the side bars of the body members.

2. As a new article of manufacture, a folding drying-frame for woolen garments, the said frame consisting of two body members and two sleeve members, each formed from a single piece of wire, and pivotally connected together for being folded to prepare the frame for transportation or storage, and one of the said members being provided with an integral coupling-hook for locking the body members in their open positions, and the lower arms of the sleeve members terminating in safety-buttons adapted to be engaged with portions of the body members for supporting the sleeve members in their open positions.

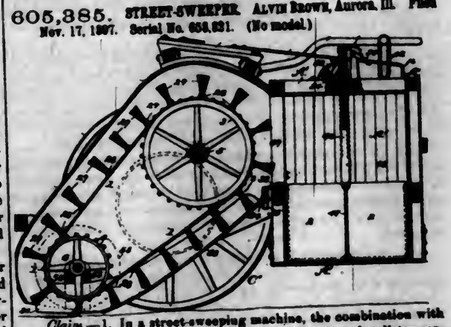
605,384. **VALVE.** ROBERT C. BROWLEY, Pittsburg, Pa. Filed Oct. 27, 1897. Serial No. 656,573. (No model.)

Claim.—1. In a valve, a central reciprocating non-rotary disk-base provided with cam-faces and centrally-mounted rotating valve-disks thereon provided with corresponding cam-faces, substantially as set forth.

2. In a valve, a central reciprocating non-rotary disk-base provided with cam-faces and centrally-mounted rotating valve-disks thereon provided with corresponding cam-faces and means for rotating the disks, substantially as set forth.

3. A valve comprising a case having oppositely-located seats, a non-rotary central base adjustably mounted on a valve-stem having inclined faces on opposite sides, and centrally-mounted rotating valve-disks thereon provided with corresponding inclined faces, and means for rotating the disks, substantially as set forth.

4. A valve comprising a case having oppositely-located seats, a non-rotary central base adjustably mounted on a valve-stem having inclined faces on opposite sides, and centrally-mounted rotating valve-disks thereon provided with corresponding inclined faces, and means for rotating and seating the disks on their inward travel and reversing and unseating the disks on their backward travel, substantially as set forth.



5. A valve comprising a case having oppositely-located seats, guides along the inner sides of the case terminating in abutting ends, abutments beyond such ends, with an intervening recess, and a non-rotary central base adjustably mounted on a valve-stem with rotating valve-disks mounted thereon having projecting arms adapted to engage such abutments and abutting ends on the forward and back travel respectively, substantially as set forth.

6. A valve comprising a case having oppositely-located seats, guides along the inner sides of the case terminating in abutting ends, abutments beyond such ends, with an intervening recess, and a non-rotary central base adjustably mounted on a valve-stem having inclined faces on opposite sides, centrally-mounted rotating valve-disks thereon provided with corresponding inclined faces, and projecting arms adapted to engage such abutments and abutting ends on the forward and back travel respectively, substantially as set forth.

7. In a valve provided with guiding edges terminating in abutting ends, abutments beyond such abutting ends, with an intervening space: rotating disks mounted on a non-rotating base and having lateral arms adapted to engage the abutments and to bear upon the abutting ends, and to reverse the disks upon backward movement, substantially as set forth.

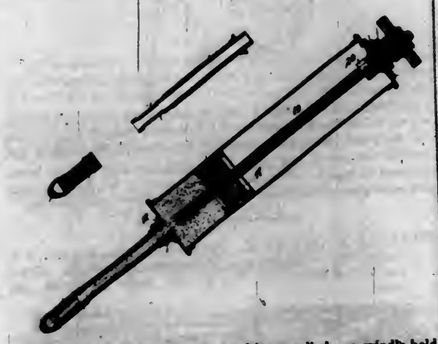
8. In a valve provided with rotating disks having lateral arms with rollers mounted therein and adapted to be seated upon the valve-faces, guiding edges for the lateral arms terminating in abutting ends, substantially as set forth.

605,385. **STREET-SWEEPER.** ALVIN BROWN, Aurora, Ill. Filed Nov. 17, 1897. Serial No. 658,631. (No model.)

Claim.—1. In a street-sweeping machine, the combination with the rear casing, a rotary brush arranged within it and a dirt-receptacle in the front casing, of a dirt-pan arranged under said rear casing and brush, a hinged apron at the front end of the pan, a transverse support for the apron and pan, vertical slots in the casing through which said supports project, and means for clamping the support in any vertical adjustment, as specified

2. In a street-sweeping machine, the combination with the casing, an endless traveling brush-belt, front and rear sprocket-wheels, on which such belt runs, the shaft of such front wheels projecting through the slotted sides of the casing, frame-bars extending along the sides of the latter and having a lengthwise slot, brackets connected with the shaft ends and having a projecting portion or rib that slides in the slots of said bars, a screw-bolt working horizontally in a threaded lug on such bars, and connected with the aforesaid bracket, for adjusting the latter as described, for the purpose of regulating the tension of the belt, as specified.

3. In a street-sweeping machine, the combination with the casing, frame, endless brush, and front and rear brush-shafts, of the means for adjusting the rear shaft vertically, which consists of vertical hangers or threaded rods, fixed perforated lugs to receive said rods and nuts applied to the latter and arranged in the space between said lugs, as shown and described.



4. In a street-sweeping machine, the combination with carrier-chains and cross-bars attached thereto, of brush-sockets brush-tufts and brush-holding wires or rods passing through said sockets and means for securing the ends of such rods to the aforesaid bars, substantially as shown and described.

5. In a street-sweeping machine, the combination with parallel carrier-chains, transverse bars which connect them as shown, a series of brush-sockets attached to said bars, and having end slots, and tufts of wires or rods passing through said slots and the brushes proper and having eyes at their extremities, and screws passing through the said eyes, for securing the rod and brushes, as specified.

6. In a street-sweeping machine, the combination, with a casing having sides adapted to open as desired, of two trays arranged transversely therein and hinged at their outer ends, their closed inner ends abutting as shown, and a hoisting device connected with such inner ends for tilting and discharging both trays simultaneously, in opposite directions laterally, as shown and described.

7. In a street-sweeping machine, the combination with a casing and brush and tray-like dirt-receptacles arranged within said casing and hinged at their open outer ends, the rack-bar arranged vertically and connected with the closed inner ends of the receptacle, a pinion provided with a crank-shaft and arranged on top of the casing, and meshing with the rack-bar, and a locking-pawl and rollers for resisting lateral thrust of the rack-bar, as shown and described.

605,886. **APPLICATOR.** CYRIL P. BROWN, Spring Lake, Mich. Filed June 19, 1897. Serial No. 641,414. (No model.)

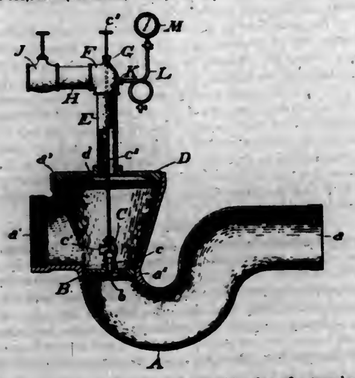
Claim.—1. An instrument comprising a cylinder, a spindle held against end movement in the cylinder, a plunger mounted to travel on said spindle, a tube secured at the outlet of the cylinder and having ports in its sides near its outer end, and a cap mounted on the tube and having a closed outer end, the said cap being provided with similar ports in its sides capable of being brought into register with the ports in the sides of the tube, substantially as described.

2. An applicator, consisting of a cylinder, plunger, a spindle on which said plunger is mounted to travel, the said spindle being held against end movement, means for turning said spindle, and a click-pawl for indicating each revolution of the spindle.

3. In an applicator, a cylinder, a threaded spindle mounted to turn in said cylinder and held against end movement, a plunger held to travel on said spindle, a tube secured at the outlet end of the cylinder and having ports in its sides near its outer end, and a cap mounted on the tube and provided with similar ports in its sides adapted to register with the ports in the sides of the tube.

4. In an applicator, a cylinder, a plunger having a threaded opening, and a threaded spindle upon which the plunger is mounted, the said threaded spindle being held against end movement in the cylinder, and means for turning the said spindle.

5. In an applicator, a cylinder, a plunger having threaded opening, a threaded spindle upon which the plunger is mounted, the said threaded spindle being held against end movement in the cylinder, means for turning said spindle, and a device engaging with the spindle and carried by the cylinder, arranged to indicate when the said spindle has completed a revolution, as and for the purpose specified.



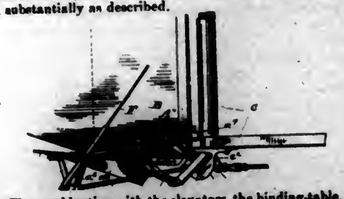
6. The combination, with a cylinder, of a plunger held to slide in the said cylinder, a screw-spindle held against end movement within the said cylinder and capable of rotary movement, the said threaded spindle engaging a threaded surface in the plunger, an outlet for the cylinder, and means for controlling the extent of the opening of the said outlet and for closing the same as desired.

7. The combination, with a cylinder, a plunger held to slide in the said cylinder, and a threaded spindle engaging with a threaded surface of the plunger, the said spindle being capable of revolving within the cylinder and of being held against end movement, of a cam-surface formed near the outer end of the said threaded spindle, and a spring-pressed pawl held in engagement with said cam-surface, for the purpose specified.

8. The combination, with a cylinder, a plunger held to slide in the said cylinder, and a threaded spindle engaging with a threaded surface of the plunger, the said spindle being capable of revolving within the cylinder and of being held against end movement, of a cam-surface formed near the outer end of the said threaded spindle, a spring-pressed pawl held in engagement with the cam-surface, a tube secured at the outlet end of the cylinder, having ports in its lower portion, and a cap adjustable on the said tube, provided with ports corresponding to those in the tube and capable of being brought in registry therewith, for the purpose described.

9. The combination with a cylinder having an outlet, a spindle mounted to turn in said cylinder and held against end movement, and a plunger mounted to travel on said spindle, of means for turning said spindle, and a device for indicating when the spindle has completed a revolution, substantially as set forth.

605,887. **TESTING-TRAP.** DAVID BUNT, Bernardsville, N. J., and EDWARD BERAKELL, New York, N. Y. Filed Jan. 31, 1898. Serial No. 668,562. (No model.)



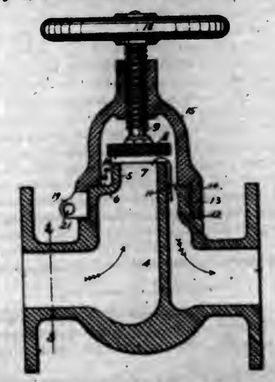
Claim.—1. In a testing-trap, the combination of a trap bend or casing having ends constructed for connection with a plumbing system and sewer-pipe, said trap having a hand-hole, a hand-hole plug, a water-retaining plug having a threaded orifice, a valve connected with said orifice, said trap having an interior portion fashioned to engage said water-retaining plug, water-supply piping opening into said trap above said water-retaining plug, a stuffing-box opening into said trap above said water-retaining plug, and a valve-stem passing through said stuffing-box whereby the valve borne by said water-retaining plug may be operated, substantially as described.

2. In a testing-trap, the combination of a trap-bend having ends constructed for connection with a plumbing system and sewer-pipe, said trap having a hand-hole c^3, a threaded hand-hole plug D having a threaded orifice d, water-supply piping connected with orifice d, an elbow included in said water-supply piping, a stuffing-box attached to said elbow, a water-retaining plug having a threaded orifice, a valve connected with said orifice, said trap having an interior portion fashioned to engage said water-retaining plug, and a valve-stem passing through said stuffing-box whereby the valve borne by said water-retaining plug may be operated, substantially as described.

605,888. **BUTT-ADJUSTER FOR SELF-BINDING HARVESTERS.** WILLIAM BUTTERFIELD, Chicago, Ill., assignor to the Deering Harvester Company, same place. Filed June 21, 1897. Serial No. 641,781. (No model.)

Claim.—1. The combination with the elevators the binding-table and the grain-cover, of a grain-adjusting device consisting of a plurality of orbitally-moved boards arranged one above the other and adapted to move in close relation to each other and also adapted to act alternately, and thus engage the butts of the straws in the receptacle, move them endwise and advance them deliveryward, each of

said boards having a plate attached to the edge adjoining its fellow board, substantially as described.



2. The combination with the elevators, the binding-table, and the grain-cover, of a grain-adjusting device consisting wholly of two orbitally-moving boards placed edgewise in close proximity to each other; the plane of said boards being substantially perpendicular to the binding-table, and said boards being operated so as to act alternately upon the butts of the straw upon the table, to simultaneously move the same endwise and sidewise, whereby only one portion of the adjuster is active upon the grain at a time, the other portion being meanwhile out of action, substantially as described.

3. The combination with the elevating-conveyers, the binding-table, and the grain-cover, of a grain-adjusting device consisting wholly of orbitally-moving boards placed edgewise in close proximity to one another, the plane of said boards being substantially perpendicular to the binder-table, and said boards being operated so that, although the entire face of the adjuster is constantly in motion, the individual boards of which it is composed act alternately upon the butts of the straw upon the table to simultaneously move the same endwise and sidewise, substantially as described.

4. In a grain-binding harvester, the combination with the receiving-table, the grain-cover, and the upper and lower elevating-conveyers, of a grain-adjusting device composed wholly of a plurality of orbitally-moving boards, one placed immediately above the other, the lower board located and adapted to sweep in close contact with the table, and the upper board located and adapted to sweep across the plane of the lower conveyer toward and near the end of the upper conveyer in close contact with the cover, and the two boards thus cooperating to clear the space between the roller of the upper conveyer and the overhead cover and between the roller of the lower conveyer and the edge of the receiving-table, substantially as described.

5. In a grain-binding harvester the combination with the binder receiving-table, grain-cover and upper and lower elevating-conveyers, of a grain-adjusting device composed of two orbitally-moving boards, one above the other, the lower one adapted to clear the space between the grain-receiving table and the lower conveyer-roller, and the upper one to keep clear the space between the upper elevator-roller and the grain-cover, and plates attached to the adjoining edges of said boards and projecting outwardly and adapted to prevent straws from getting between said boards, substantially as described.

605,889. GLOBE-VALVE. CORNELIUS M. CALLAHAN, Buffalo, N. Y. Filed May 15, 1897. Serial No. 636,736. (No model.)

Claim.—1. In combination a valve-casing and a cap therefor screw-threaded to the said casing, one of the said parts being slitted and having clamping-lugs projecting from opposite sides of the slit, and a screw-bolt designed to be received by the lugs as and for the purpose set forth.

2. The combination with a valve-casing provided with an externally screw-threaded dome, of a valve-cap provided with a slit and internally-screw-threaded flange, a pair of clamping-lugs projecting from the threaded flange of the cap upon the opposite sides of the slit, and a screw-bolt, designed to be received by the clamping-lugs, substantially as specified.

3. The combination with a valve-casing provided with a dome-plate having ports and a projecting annular valve-seat, of a valve-cap provided with an internally-screw-threaded and transversely-slitted thread-flange, clamping-lugs projecting from the threaded flange of the cap and a clamping screw-bolt designed to be received by the lugs, substantially as specified.

4. The combination with a valve-casing provided with a dome-plate having ports and an upwardly-projecting annular valve-seat, of a valve-cap provided with a slitted thread-flange internally screw-threaded and designed to engage corresponding threads upon the dome of the valve-casing, clamping-lugs upon the threaded flange, a bolt designed to be received by the lugs, a wrench-collar upon the upper extremity of the cap, a valve-stem carried by said cap and provided with a valve in operative proximity to the valve-seat and means for actuating said valve, substantially as specified.

605,890. BICYCLE TOE-CLIP. HARRY W. CALVERT, McKees Rocks, Pa. Filed June 23, 1897. Serial No. 641,948. (No model.)

Claim.—In a toe-clip, a strap secured to the pedal, bent to form a pocket for the front part of the foot, arms formed integral with the strap and being bent outwardly and downwardly to form side guards, the ends of said arms being bent upwardly to form hooks adapted to engage underneath the cross-plate of the pedals to limit the movement of the strap, substantially as shown and described.

605,891. CAR-WHEEL. FERDINAND R. CARDA, New York, N. Y. Original application filed Sept. 11, 1896, Serial No. 605,486. Divided and this application filed Sept. 27, 1897. Serial No. 653,148. (No model.)

Claim.—1. A car-wheel having a cast-steel hub and rim connected by a series of spokes formed separately from the hub and rim, from a tough welding metal, and welded into the hub and rim so as to produce an integral wheel, substantially as described.

2. A car-wheel having a cast-steel hub and rim connected by a series of spokes formed separately from the hub and rim, from a tough welding metal, bent to offset the hub from the rim, and welded into the hub and rim so as to produce an integral wheel, substantially as described.

3. A car-wheel having a cast-steel hub and rim and T-section spokes, formed separately from the hub and rim, from a tough welding metal, and welded into the hub and rim so as to produce an integral wheel, substantially as described.

605,892. PROPELLING MEANS FOR BICYCLES OR SIMILAR VEHICLES. HERCULES CAVIGNI, Plattsburg, N. Y. Filed Mar. 31, 1897. Serial No. 630,121. (No model.)

Claim.—1. In a bicycle or similar vehicle, a pair of rock-arms journaled in the frame, treadle-levers carried by said shafts upon opposite sides of the frame, arms carried by said shafts upon one side and extending in opposite directions, a wheel journaled in the frame, pitmen having their forward ends connected to the extremities of the arms and their rear ends connected to the said wheel by a common pivot, and driving connections from the said wheel to the rear wheel of the bicycle, substantially as described.

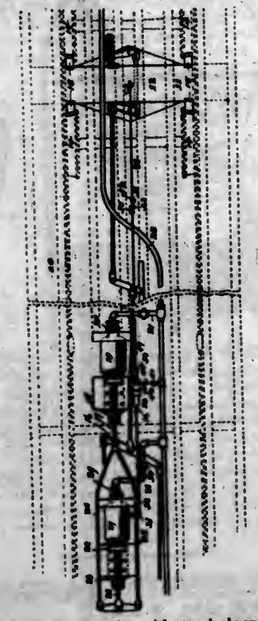
2. In a bicycle or similar vehicle, a pair of rock-shafts journaled in the frame, one above the other, treadles carried by said shafts upon

opposite sides of the frame, an arm carried by the upper shaft extending upwardly and a similar arm carried by the lower one extending downwardly, a sprocket-wheel journaled in the frame, a pitman extending from the extremity of each arm to the said wheel, a sprocket-wheel connected to the hub of the driving-wheel, and a chain connecting said wheels, the said oppositely-extending arms being on the same side of the frame, substantially as described.

3. In a bicycle, a frame having two bars or rods extending from the steering-head to the rear wheel, a box or hanger supported from the said bars or rods, a cross-bar connecting said bars in rear of the hanger or box; and a saddle-post rod having its lower end extending through the cross-bar and carried forward between the said bars and connected to the said box or hanger, substantially as described.

605,893. FENCE. FRANK CHILDERS, Wolf Creek, Ill. Filed Feb. 20, 1893. Serial No. 671,609. (No model.)

Claim.—1. In a wire fence, a fence-post made up of two flat sections located at right angles one to the other throughout the greater part of their length, the upper end of one of the sections being twisted forming a portion which lies parallel to the other section, a bolt extending through the two parallel portions of said section for securing the same together, and line wires located between said sections, as and for the purpose set forth.



2. In a wire fence, a fence-post made up of two flat sections lying at right angles one to the other throughout the greater portion of their length, one of said sections being bent at right angles at its lower end forming a wing or anchor, and the other of said sections having its upper end twisted forming a portion which lies parallel to the first section, a securing-bolt extending through the parallel portions of said sections, and line-wires passing between said sections, as and for the purpose set forth.

3. In a wire fence, a fence-post made up of two flat sections lying at right angles one to the other throughout the greater portion of their length, one of said sections having a laterally-extending wing at its lower end constituting an anchor, and the other of said sections having notches formed in the edge thereof which abuts against the side of the first section, and has its upper end twisted forming a portion which lies parallel to the first section, a securing-bolt extending through the parallel portions of said sections, and line-wires passing between said sections and fitting within said notches, as and for the purpose set forth.

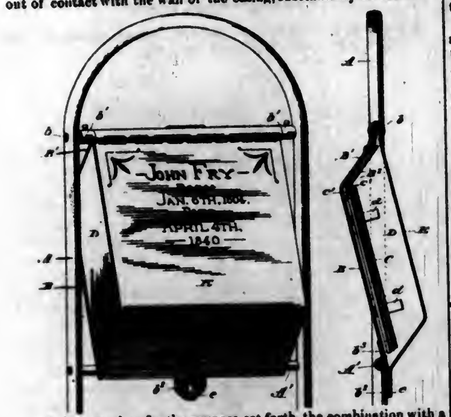
4. In a wire fence, the combination with one of the posts thereof, having notches in one of its side edges, of line-wires secured to said post, a diagonally-disposed bracing rod or bar whose pointed upper end is adapted to engage said notches and whose lower end is secured to a stationary support, and connections between said bracing-rod and said line-wires, as and for the purpose set forth.

5. A fence-post, made up of two sections, one of which is provided with notches for the passage of line-wires, and both of which are provided with notches for the reception of securing-loops which embrace said sections for the purpose of holding the line-wires in place.

605,894. AIR-BRAKE. WILLIAM H. CLOWRY, Chicago, Ill. Filed Jan. 3, 1898. Serial No. 665,563. (No model.)

Claim.—1. The combination, with a car body and truck, and air-braking mechanism therefor, of an auxiliary brake-cylinder having its piston connected with the braking mechanism, a valve controlling the connection between said auxiliary cylinder and the train brake-pipe, a fluid-motor for operating said valve, and means operated by the variations in height of the car-body for actuating said fluid-motor, substantially as described.

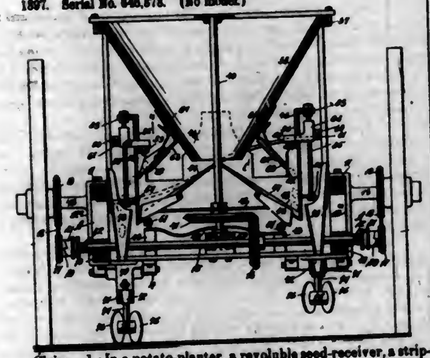
2. The combination, with a car body and truck, and air-braking mechanism therefor, of an auxiliary brake-cylinder and reservoir provided with a triple valve connected with the train brake-pipe, an outlet-valve and a valve controlling the connection with the train brake-pipe, and means operated by the variations in height of the car-body for actuating said controlling-valve and outlet-valve, substantially as described.



3. The combination, with a car body and truck, and air-braking mechanism therefor, of an auxiliary brake-cylinder having its piston connected with the braking mechanism, a valve controlling the connection between said auxiliary cylinder and the train brake-pipe, means whereby a normal depression of the car-body will open said controlling-valve, and means whereby an abnormal depression of the car-body will cut out said auxiliary brake-cylinder, substantially as described.

605,895. MARKER FOR GRAVES, LANDS, &c. JOHN A. COFFEY, Anaconda, Mont. Filed Nov. 11, 1897. Serial No. 658,143. (No model.)

Claim.—1. In a marker for the purpose set forth, the combination with a supporting-frame having a cross-bar *b* attached thereto, a casing rigidly attached to the bar and frame, the casing consisting of rear, front and side pieces, the rear plate B being bent to present a downward and rearward inclined top and a downward and forward inclined portion below, the side pieces D being attached to the rear plate and a covering-plate E held in swinging engagement with the cross-bar and adapted to lie over the side pieces D carried by the rear plate, hooks B^3 attached to the under side of the upper portion of the rear plate and tablets suspended from the hook said tablets being maintained in an inclined position, substantially as shown.



2. In combination with a casing and suspended covering plate therefor, hooks attached to the inner upper wall of the casing, cross-bars *d d* attached to the side wall of the casing, said cross-bars extending over the inner wall thereof and out of contact therewith, of

tablets having eyes for engagement with the hooks said tablets resting upon the cross-bar so as to be maintained in an inclined position out of contact with the wall of the casing, substantially as shown.

3. In a marker for the purpose set forth, the combination with a casing and its support, the casing comprising a rear plate bent so that its upper portion will incline rearward and downward the continuation of the plate extending from the bend downward and toward the front, means as shown for rigidly attaching the rear plate to the support, lozenge-shaped side pieces rigidly attached to the edges of the back plate, a covering-plate in swinging engagement with the rear plate, the same adapted to swing by gravity downward so as to lie over the front edges of the side pieces, hooks attached to the upper portion of the rear plate within the casing and tablets which engage with the hooks and depend therefrom in an inclined position, substantially as shown.

605,896. POTATO-PLANTER. JOHN A. COOPER, Summit, Iowa, assignor of one-half to Arthur C. Savage, Adair, Iowa. Filed Aug. 3, 1897. Serial No. 646,873. (No model.)

Claim.—1. In a potato-planter, a revoluble seed-receiver, a stripping device carried by the receiver, a picking device also carried by the receiver, and means for moving one of said devices to or from the other as the receiver revolves.

2. In a potato-planter, a revoluble seed-receiver, a stripping device stationary on said receiver, a picking device adapted to take up seed from the receiver and mounted on the receiver for movement to and from the stripping device, and means, substantially as described, for carrying the picking device to the stripping device and subsequently releasing the picking device.

3. In a potato-planter, a revoluble seed-receiver, a stripping device secured to said receiver, a picking device mounted to slide on said receiver to and from the picking device, said picking device being provided with a projection, and inclined tracks independent of the receiver, said tracks being in engagement with the projections from the picking device.

4. In a potato-planter, the combination, with a revoluble seed-receiver, a stripping device secured to said receiver, and a picking device mounted to slide on the receiver to and from the stripping device, said picking device being provided with a lateral projection, of spiral tracks arranged one at each side of the receiver, independent thereof, the lower end of one track being beneath the higher end of the opposing track, the tracks being engaged by the projection from the picking device.

5. In a potato-planter, a revoluble seed-receiver, a picker and a stripping device for the picker, carried by said receiver, the receiver being provided adjacent to the path of each picker with an opening in its bottom, a cleaning device located in each of said openings, and means, substantially as described, for imparting vertical movement to the said cleaning devices as the receiver is revolved.

6. In a potato-planter, the combination, with a revoluble seed-receiver, a stationary stripping device carried thereby, a picking device having movement to and from the stripping device, and means for operating the said picking device, of cleaning-blades located in the bottom of the receiver adjacent to that portion at which the picking device has movement, the said cleaning-blades being capable of vertical movement within the receiver, an undulating stationary track, and rollers carried by the cleaning-blades, arranged to travel on said track.

7. In a potato-planter, the combination, with a rotatable seed-receiver, and picking and stripping devices carried by said receiver, of platforms independent of and located within the said seed-receiver, said platforms being arranged to receive the seed when stripped from the picker.

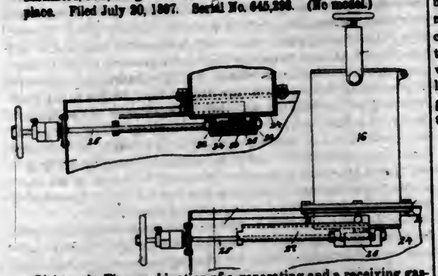
8. In a potato-planter, the combination, with a seed receiver or receptacle provided with stationary strippers and picking devices movable to and from the said strippers, of platforms located within yet independent of the said seed-receiving receptacle, being adapted to receive the seed when dropped from the pickers, and means, substantially as described, for adjusting the position of the platforms relative to the pickers.

9. In a potato-planter, the combination, with a hopper, a seed-receiving receptacle mounted to revolve around said hopper, stationary strippers carried by said receptacle, pickers also carried by the receptacle, having movement to and from the strippers, and means, for operating said pickers, the seed-receptacle being provided with openings between the sections at which the strippers and pickers are located, of platforms adjustably supported from the hopper, and levers for adjusting said platforms.

10. In a potato-planter, the combination, with a hopper, a seed-receiving receptacle mounted to revolve around said hopper, stationary strippers carried by said receptacle, pickers also carried by the receptacle, having movement to and from the strippers, and means, for operating said pickers, the seed-receptacle being provided with openings between the sections at which the strippers and pickers are located, of platforms adjustably supported from the hopper, levers connected one with each platform, cleaning-blades having vertical movement in the bottom of the seed-receptacle, an undulating track upon which the said blades travel, for the purpose specified.

11. In a potato-planter, the combination, with a chute adapted to receive the seed-potatoes, and a runner pivotally connected with the frame of the machine, the said runner being provided with an opening registering with the outlet of said chute, of a covering device located at the rear of the opening in the runner, the covering device consisting of a post and cupped disks having their concaved faces opposite each other, the disks being pivoted to the said post at an angle one to the other so that their rear ends converge and their forward ends diverge.

12. The combination, with the pole of a wheeled vehicle, of an arm pivoted over said pole, a draft device pivoted to the free end of the said arm, and levers having a shifting connection with the said arm.

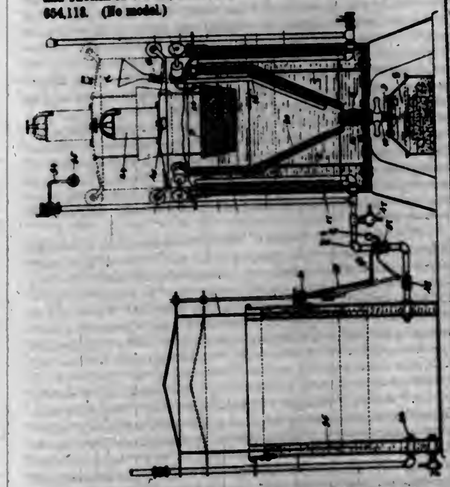


13. In a planter or like machine adapted to plant seed or deliver material from opposite sides, an arm pivoted over the tongue or pole of the vehicle, a draft device pivoted to the free end of the said arm, a shifting lever, and a flexible connection between said lever and said arm, whereby the arm may be held over the tongue, or at the right or the left of the tongue to control the draft of the machine.

14. In a potato-planter, the combination with a revoluble receiver having openings in its bottom, of cleaning-blades pivoted in said openings, rollers secured to the under face of the free ends of the blades, and an undulating track below the receiver and upon which the said rollers travel, substantially as described.

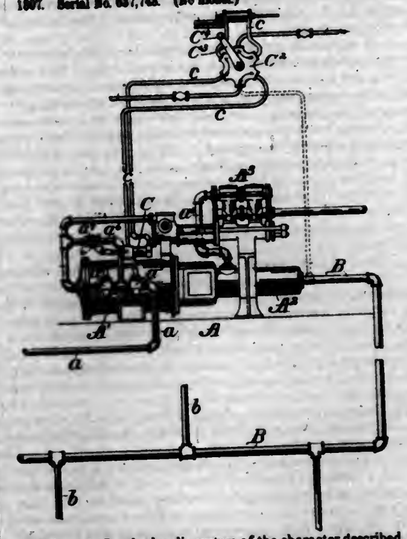
15. In a potato-planter, the combination with a revoluble receiver, a stripper secured to the receiver and provided with tines, a picker mounted on the receiver to slide vertically and provided with downwardly-projecting tines, spiral tracks one at each side of the receiver, and a roller carried by the picker and traveling on said tracks, substantially as described.

16. In a potato-planter, the combination with a hopper, a revoluble receiver below the hopper, a chute adjacent to the receiver, and a picker and stripping device carried by the receiver, of an inclined platform adjustably secured to the hopper, substantially as and for the purpose set forth.



605,897. ACETYLENE-GAS GENERATOR. JAMES H. COOPER, Baltimore, Md., assignor to the Bryan Manufacturing Company, same place. Filed July 20, 1897. Serial No. 645,226. (No model.)

Claim.—1. The combination of a generating and a receiving gasometer, a pipe connecting the gas-spaces of both, a valve in said pipe, operating mechanism for the valve controlled by the movable part of the receiving-gasometer, a receptacle mounted on the movable part of the generating-gasometer, the top of said receptacle opening outward and bottom inward, means for clamping the top in place, a hand-wheel and rod extending from the bottom to the exterior of the gasometer, a nut operated by the rod said nut engaging with a lug on the bottom of the receptacle in such a way that when the rod is turned in one direction the nut engages with the lug and clamps the bottom, and when turned in the opposite direction unclamps the bottom which may then be drawn from under the receptacle by means of the rod, a perforated partition carried by the movable part of the generating-gasometer to receive calcium carbid or other material from the receptacle, and a safety-valve connected to the gas-space of generating-gasometer and operated mechanically by the movable part thereof.



2. In a calcium-carbid receptacle having a removable bottom, the combination of a pair of parallel guides one on each side of the receptacle at its lower edge, a yoke the ends of which rest in and slide in said guides, said yoke being provided with perforated lugs, a threaded rod passing through said lugs, and secured therein so as to turn, but not move laterally, a nut upon said rod adapted to move in a direction parallel to the rod and having its upper surface beveled, and the bottom resting upon and guided by the yoke, and provided with a beveled lug on its under side, which engages with the beveled surface of the nut; the whole yoke and bottom being moved back and forth by the rod in a direction parallel to it, and the bottom being clamped in position by the nut, substantially as described.

605,898. ACETYLENE-GAS GENERATOR. JAMES H. COOPER and THOMAS A. BRYAN, Baltimore, Md. Filed Oct. 5, 1897. Serial No. 654,113. (No model.)

Claim.—An acetylene-gas generator composed of a stationary wall and a gas holder, adapted to float therein, the walls of said well being packed with a suitable non-conductor of heat and constructed to be filled with a fluid having a low freezing temperature, a water-receptacle submerged in said fluid, and contained within the well and holder, the walls of said receptacle also constructed to contain a material which is a poor non-conductor of heat, and a perforated receptacle for calcium carbid suspended from the holder and adapted to be dipped into the water as the gas is drawn off, in combination with a gasometer connected to the generator by a pipe with a self-lubricating valve located therein and operated by the float of the gasometer in such a way as to open the pipe when the float is down, thereby admitting gas from the generator.

605,899. HYDRAULIC MECHANISM FOR CLOSING BULK-HEAD-DOORS. WILLIAM B. COWLES, Cleveland, Ohio. Filed May 22, 1897. Serial No. 637,743. (No model.)

Claim.—1. In a hydraulic system of the character described, the combination with a receptacle adapted to contain a body of fluid under pressure, and means for regulating the pressure of said fluid, of an emergency-cylinder, with piston therein, and emergency mechanism operated by said piston, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe and an exhaust-pipe, and means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, a door, and means operated by the emergency mechanism for moving said door, with additional means operated by the fluid-pressure and controlled by hand for moving said door independently of the emergency mechanism, substantially as described.

2. In a hydraulic system of the character described, the combination with a receptacle adapted to contain a body of fluid under pressure, and means for regulating the pressure of said fluid, of an emergency-cylinder, with piston therein, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe and an exhaust-pipe, and means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, a fluid-pressure main, branch pipes leading from said main, a bulk-head-door, and mechanism operated by the fluid in said branch pipes for moving said door, and mechanism operated by the piston in the emergency-cylinder for controlling the pressure in all of said branch pipes, substantially as described.

3. In a hydraulic system of the character described, the combination with a receptacle adapted to contain a body of fluid under pressure, and means for regulating the pressure of said fluid, of an emergency-cylinder, with piston therein, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe and an exhaust-pipe, and means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, a fluid-pressure main, branch pipes leading from said main, a bulkhead-door, and mechanism operated by the fluid in said branch pipes for moving said door, mechanism operated by the piston in the

emergency-cylinder for controlling the pressure in all of said branch pipes, and a releasing-valve connected to each of said branch pipes and adapted to control the flow of fluid through said branch pipe and thus to control the mechanism operated thereby, substantially as described.

4. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam-cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with piston therein and emergency mechanism operated by said piston, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe, a bulk-head-door, and mechanism operated by fluid-pressure in the system for moving said door, an exhaust-pipe, and means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, substantially as described.

5. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam-cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with piston therein, an emergency-valve operated by said piston, and a hydraulic system controlled by said emergency-valve, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe, a bulkhead-door, and mechanism operated by fluid-pressure in the system for moving said door, an exhaust-pipe, and means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, substantially as described.

6. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam-cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with piston therein and emergency mechanism operated by said piston, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe, a bulk-head-door, and mechanism operated by fluid-pressure in the system for moving said door, an exhaust-pipe, and a six-way valve for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, substantially as described.

7. In a hydraulic system of the character described, the combination with a receptacle adapted to contain a body of fluid under pressure, and means for regulating the pressure of said fluid, of an emergency-cylinder, with piston therein and emergency mechanism operated by said piston, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe, a bulkhead door, and mechanism operated by fluid-pressure in the system for moving said door, an exhaust-pipe, and a six-way valve for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, substantially as described.

8. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam-cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with piston therein, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe and an exhaust-pipe, and means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe, and from the other end of the cylinder to the exhaust-pipe, or vice versa, a fluid-pressure main leading from the ram-cylinder, branch pipes leading from said main, bulkhead-doors, and mechanism operated by the fluid in said branch pipes for moving said doors and mechanism operated by the piston in the emergency-cylinder for regulating the pressure in the steam-cylinder and so controlling the pressure in all of said branch pipes, substantially as described.

9. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam-cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with piston therein, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe connected to said ram-cylinder and an exhaust-pipe, and a six-way valve for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, a fluid-pressure main, leading from the ram-cylinder, branch pipes leading from said main, bulkhead doors, and mechanism operated by the fluid in said branch pipes for moving said doors, and mechanism operated by the piston in the emergency-cylinder for regulating the pressure in the steam-cylinder and so controlling the pressure in all of said branch pipes, substantially as described.

10. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam-cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with pistons therein, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe and an exhaust-pipe, and means for connecting the pipe from one end of the cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, a fluid-pressure main leading from the ram-cylinder, branch pipes leading from said main, a plurality of bulkhead-doors, door opening and closing mechanism operated by the fluid in said branch pipes and mechanism operated by the piston in the emergency-cylinder for controlling the pressure in the ram-cylinder and so in all of said branch pipes, substantially as described.

11. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam-cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with piston therein, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe and an exhaust-pipe, means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, and means for indicating the flow of fluid through said pipes, a fluid-pressure main leading from the ram-cylinder, branch pipes leading from said main, a plurality of bulkhead-doors, door opening and closing mechanism operated by the fluid in said branch pipes and mechanism operated by the piston in the emergency-cylinder for controlling the pressure in all of said branch pipes, substantially as described.

12. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam-cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with piston therein, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe and an exhaust-pipe, and means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, a fluid-pressure main connected to said ram-cylinder, branch pipes leading from said main, bulkhead-doors, mechanism operated by the fluid in said branch pipes for moving said doors, mechanism operated by the piston in the emergency-cylinder for controlling the pressure in all of said branch pipes, and a releasing-valve connected to each of said branch pipes and adapted to control the flow of fluid through said branch pipe and to control the mechanism operated thereby, substantially as described.

13. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam-cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with piston therein, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe and an exhaust-pipe, and means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, a fluid-pressure main connected to said ram-cylinder, branch pipes leading from said main, a plurality of bulkhead-doors, door opening and closing mechanism operated by the fluid in said branch pipes and mechanism operated by the piston in the emergency-cylinder for controlling the pressure in all of said branch pipes, and a hand-operated releasing-valve connected to each of said branch pipes and adapted to control the flow of fluid through said branch pipe and to control the door opening and closing mechanism operated thereby, substantially as described.

14. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with piston therein, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe and an exhaust-pipe, and means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, a fluid-pressure main connected to said ram-cylinder, branch pipes leading from said main, a plurality of bulkhead-doors, door opening and closing mechanism operated by the fluid in said branch pipes and mechanism operated by the piston in the emergency-cylinder for controlling the pressure in all of said branch pipes, and a hand-operated releasing-valve connected to each of said branch pipes and adapted to control the flow of fluid through said branch pipe and to control the mechanism operated thereby, with springs adapted to automatically return said releasing-valve to the initial position, substantially as described.

15. In a hydraulic system of the character described, the combination with a ram-cylinder adapted to contain a body of fluid under pressure, and a steam-cylinder for exerting pressure upon said fluid, with valves for regulating the said pressure, of an emergency-cylinder, with piston therein, pipes respectively connected to each end of said cylinder and adapted to contain fluid under pressure, a fluid-pressure pipe and an exhaust-pipe, and means for connecting the pipe from one end of said cylinder to the fluid-pressure pipe and from the other end of the cylinder to the exhaust-pipe, or vice versa, a fluid-pressure main leading from the ram-cylinder, branch pipes leading from said main, doors provided with cylinders operated by the fluid in said branch pipes, a valve operated by the piston in the emergency-cylinder for controlling the pressure in the steam-cylinder and thus regulating the pressure in the ram-cylinder and in all of said branch pipes, and a hand-operated releasing-valve connected to each of said branch pipes and adapted to control the flow of fluid through said branch pipe and to control the mechanism operated thereby, substantially as described.

16. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure and itself operated by fluid from the source of fluid-pressure, means for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, a branch pipe from said main, a bulkhead-door, and mechanism operated by the fluid in said branch pipe for moving said door, and releasing-valve mechanism located in said branch pipe and operated by hand at low pressures and automatically operated at high pressures, substantially as described.

17. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain a body of fluid under pressure, a plurality of reducing-valves for regulating the admission of fluid-pressure from said source to said accumulator, a by-pass opening from between said reducing-valves into said accumulator, a valve controlling said by-pass, means for operating said valve, a bulkhead-door, and mechanism operated by the fluid-pressure from the accumulator for moving said door, substantially as described.

18. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain a body of fluid under pressure, a plurality of reducing-valves for regulating the admission of fluid-pressure from said source to said accumulator, a by-pass opening from between said reducing-valves into said accumulator, a valve controlling said by-pass, means for operating said valve, a fluid-pressure main connected to said accumulator, branch pipes connected to said main, bulkhead-doors, and mechanism operated by the fluid-pressure in said branch pipes for moving said doors, substantially as described.

19. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain a body of fluid under pressure, a plurality of reducing-valves for regulating the admission of fluid-pressure from said source to said accumulator, a by-pass opening from between said reducing-valves into said accumulator, a valve controlling said by-pass, means for operating said valve, a fluid-pressure main connected to said accumulator, branch pipes connected to said main, bulkhead-doors and door opening and closing mechanism operated by the fluid-pressure in said branch pipes, substantially as described.

20. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain a body of fluid under pressure, a plurality of reducing-valves for regulating the admission of fluid-pressure from said source to said accumulator, a by-pass opening from between said reducing-valves into said accumulator, a valve controlling said by-pass, means for operating said valve, a fluid-pressure main connected to said accumulator, branch pipes connected to said main, bulkhead-doors, and mechanism operated by the fluid-pressure in the branch pipes for opening and closing said doors, and a hand-operated releasing-valve in each of said branch pipes, whereby said doors may be operated by hand when desired, substantially as described.

21. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain a body of fluid under pressure, a plurality of reducing-valves for regulating the admission of fluid-pressure from said source to said accumulator, a by-pass opening from between said reducing-valves into said accumulator, a valve controlling said by-pass, means for operating said valve, a fluid-pressure main bulkhead-doors connected to said accumulator, branch pipes connected to said main, and door opening and closing mechanism operated by the fluid-pressure in said branch pipes, and a hand-operated releasing-valve in each of said branch pipes, substantially as described.

22. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure and itself operated by fluid from the source of fluid-pressure, a plurality of reducing-valves interposed between the source of fluid-pressure and the accumulator, with a by-pass between said valves and the accumulator, for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, a branch pipe from said main, a bulkhead-door, mechanism operated by the fluid in said branch pipe for opening and closing said door, and a releasing-valve located in said branch pipe and operated by hand at low pressures and automatically operated at high pressures, substantially as described.

23. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure and itself operated by fluid from the source of fluid-pressure, a plurality of reducing valves interposed between the source of fluid-pressure and the accumulator, for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, a branch pipe from said main, a bulkhead-door, door opening and closing mechanism operated by the fluid in said branch pipe, and a releasing-valve located in said branch pipe and operated by hand at low pressures and automatically operated at high pressures, substantially as described.

24. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure and itself operated by fluid from the source of fluid-pressure, a plurality of reducing-valves interposed between the source of fluid-pressure and the accumulator, with a by-pass between said valves and the accumulator, for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, a branch pipe from said main, a sliding door, a cylinder and piston one of which is fast to the door and the other to the framework or bulkhead surrounding the door, and the movable part being operated by the fluid in said branch pipe, and a releasing-valve located in said branch pipe and operated by hand at low pressures and automatically operated at high pressures, substantially as described.

25. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure and itself operated by fluid from the source of fluid-pressure, for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, a branch pipe from said main, a bulkhead-door and door opening and closing mechanism operated by the fluid in said branch pipe, and a releasing-valve located in said branch pipe and operated by hand at low pressures and automatically operated at high pressures, substantially as described.

26. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure, means for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, a branch pipe from said main, a sliding door, a cylinder and piston one of which is fast to the door and the other to the framework or bulkhead surrounding the door, and the movable part being operated by the fluid in said branch pipe, and a releasing-valve located in said branch pipe and operated by hand at low pressures and automatically operated at high pressures, substantially as described.

27. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure and itself operated by fluid from the source of fluid-pressure, means for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, branch pipes from said main, bulkhead-doors, and mechanism operated by the fluid in said branch pipes for moving said doors, and releasing-valves located in each of said branch pipes and separately operated by hand at low pressures and simultaneously automatically operated at high pressures, substantially as described.

28. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure and itself operated by fluid from the source of fluid-pressure, a plurality of reducing-valves interposed between the source of fluid-pressure and the accumulator for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, branch pipes from said main, bulkhead-doors, and mechanism operated by the fluid in said branch pipes for moving said doors, and releasing-valves located in each of said branch pipes and separately operated by hand at low pressures and simultaneously automatically operated at high pressures, substantially as described.

29. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure and itself operated by fluid from the source of fluid-pressure, means for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, branch pipes from said main, bulkhead-doors, and door opening and closing mechanism operated by the fluid in said branch

pipes, and releasing-valves located in each of said branch pipes and separately operated by hand at low pressures and simultaneously automatically operated at high pressures, substantially as described.

30. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure and itself operated by fluid from the source of fluid-pressure, means for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, branch pipes from said main, a sliding door, a cylinder attached to said door, a fixed piston, and a hollow piston rod connected to said branch pipe and opening into the cylinder, whereby the door is operated by the fluid in said branch pipes, and releasing-valves located in each of said branch pipes and separately operated by hand at low pressures and simultaneously automatically operated at high pressures, substantially as described.

31. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain fluid under pressure and itself operated by fluid from the source of fluid-pressure, means for regulating the pressure of the fluid in the accumulator, a fluid-pressure main leading from the accumulator, branch pipes from said main, a sliding door, a cylinder attached to said door, a fixed piston, and a hollow piston-rod connected to said branch pipe and opening into the cylinder, whereby the door is operated by the fluid in said branch pipes, and releasing-valves located in each of said branch pipes and separately operated by hand at low pressures and simultaneously automatically operated at high pressures, substantially as described.

32. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain a body of fluid under pressure, a plurality of reducing-valves for regulating the admission of fluid-pressure from said source to said accumulator, a by-pass opening from between said reducing-valves into said accumulator, a valve controlling said by-pass, means for operating said valve, bulkhead-doors, and door opening and closing mechanism operated by the fluid-pressure from the accumulator, substantially as described.

33. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain a body of fluid under pressure, a plurality of reducing-valves for regulating the admission of fluid-pressure from said source to said accumulator, a by-pass opening from between said reducing-valves into said accumulator, a valve controlling said by-pass, a hydraulic system for operating said valve, bulkhead-doors, and door opening and closing mechanism operated by the fluid-pressure from the accumulator, substantially as described.

34. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain a body of fluid under pressure, a pair of reducing-valves for regulating the admission of fluid-pressure from said source to said accumulator, a by-pass opening from between said reducing-valves into said accumulator, a valve controlling said by-pass, a hydraulic system operated by pressure from the accumulator for operating said valve, a fluid-pressure main connected to said accumulator, branch pipes connected to said main, bulkhead-doors and mechanism operated by the fluid-pressure in said branch pipes for moving said doors, substantially as described.

35. In a hydraulic system of the character described, the combination with a source of fluid-pressure, of an accumulator adapted to contain a body of fluid under pressure, a plurality of reducing-valves for regulating the admission of fluid-pressure from said source to said accumulator, a by-pass opening from between said reducing-valves into said accumulator, a valve controlling said by-pass, a hydraulic system operated by pressure from the accumulator for operating said valve, a fluid-pressure main connected to said accumulator, branch pipes connected to said main, bulkhead-doors and door opening and closing mechanism operated by the fluid-pressure in said branch pipes, substantially as described.

36. In a hydraulic system of the character described, the combination with a fluid-pressure main and a branch pipe leading therefrom, and means for raising and lowering the pressure in said main, of a bulkhead-door, and door opening and closing mechanism operated by the pressure in said branch pipe, and a releasing-valve located in said branch pipe, and adapted to be operated by hand at all pressures and to be operated automatically at high pressures only, substantially as described.

37. The combination with a frame secured to the bulkhead and provided with guides for the edges of the door, of a door sliding in said guides and provided with a plurality of inclined bearing-surfaces with projections at the base of said surfaces, a plate sliding between said inclined surfaces and the frame and itself having inclined surfaces oppositely disposed to those on the door, balls or rollers interposed between the inclined surfaces on the door and on the said plate, and means for starting the door before said plate, in opening the door, and for stopping the door after said plate, in closing the door, substantially as described.

38. The combination with a frame secured to the bulkhead and provided with guides for the edges of the door, of a door sliding in said guides and provided with a plurality of inclined bearing-surfaces with projections at the base of said surfaces, a plate sliding between said inclined surfaces and the frame and itself having inclined surfaces oppositely disposed to those on the door, balls or rollers interposed between the inclined surfaces on the door and on the said plate, and a pivoted toe adapted to lock said plate against motion when the door is in the early stages of opening or the late stages of closing, substantially as described.

39. The means for tightening the sides of a sliding door which consists in providing oppositely-inclined surfaces on the door and next the framework, with balls or rollers interposed between the said oppositely-inclined surfaces, substantially as and for the purposes described.

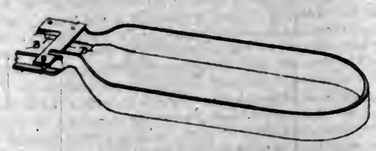
40. The means for tightening the bottom or edge of a sliding door comprising a wedge-shaped heel-piece on the door and a pivoted flap-piece adapted to engage the said heel-piece, substantially as described.

41. The means for tightening the bottom or edge of a sliding door comprising a wedge-shaped heel-piece on the door, and a pivoted flap-piece adapted to engage the said heel-piece, with inclined inner face, and springs normally pressing said inner face against the door-sill when the door is open, substantially as described.

42. The means for tightening the bottom or edge of a sliding door comprising a wedge shaped heel-piece on the door and a pivoted flap-piece adapted to engage the said heel-piece, with inclined inner face, and springs normally pressing said inner face against the door-sill when the door is open, and rollers engaging said heel-piece and pressing said flap-piece back against the action of said springs as the door descends, substantially as described.

43. The means for tightening the top or edge of a sliding door which comprise wedge-shaped rib or ribs secured to the door-frame and a hook or hooks secured to the door and adapted to engage said rib or ribs when the door nears the closed position, substantially as described.

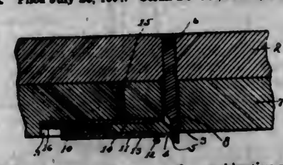
44. In a hydraulic system for opening and closing sliding doors or moving other bodies, the combination with a supply-pipe from the source of fluid-pressure, and an exhaust-pipe, of a fixed hollow piston-rod with separate passages therethrough to the upper and lower sides of the piston, respectively, a cylinder secured to the door or other body to be moved, double pipes connecting the passages in the piston-rod to the supply-pipe, and a four-way valve for connecting one of the passages in the piston-rod to the supply-pipe, and the other to the exhaust, or vice versa, substantially as described.



45. In a hydraulic system for opening and closing sliding doors or moving other bodies, the combination with a supply-pipe from the source of fluid pressure, and an exhaust-pipe, of a fixed hollow piston-rod with separate passages therethrough to the upper and lower sides of the piston, respectively, a cylinder secured to the door or other body to be moved, double pipes connecting the passages in the piston-rod to the supply-pipe, and a four-way valve for connecting one of the passages in the piston-rod to the supply-pipe, and the other to the exhaust, or vice versa, with means for operating this valve by hand at all pressures, or automatically at high pressures only, substantially as described.

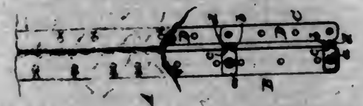
46. In a hydraulic system for opening and closing sliding doors, the combination with a door and rigid guides therefor, of a supply-pipe from the source of fluid-pressure and an exhaust-pipe, a fixed hollow piston-rod with separate passages therethrough to the upper and lower sides of the piston, respectively, a cylinder secured to the door, double pipes connecting the passages in the piston-rod to the supply-pipe, a four-way valve for connecting one of the passages in the piston-rod to the supply-pipe, and the other to the exhaust, or vice versa, and tightening devices automatically operated by the motion of the door, substantially as described.

47. In a hydraulic system for opening and closing sliding doors, the combination with a door and rigid guides therefor, of a supply-pipe from the source of fluid-pressure and an exhaust-pipe, a fixed hollow piston-rod with separate passages therethrough to the upper and lower sides of the piston, respectively, a cylinder secured to the door, double pipes connecting the passages in the piston-rod to the supply-pipe, a four way valve for connecting one of the passages in the piston-rod to the supply-pipe, and the other to the exhaust, or vice versa, and tightening devices automatically operated by the motion of the door, with means for operating this valve by hand at all pressures, or automatically at high pressures only, substantially as described.



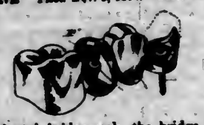
605,400. CUTTER AND HOLDER FOR FRUIT, FLOWERS, &c. WILLIAM W. CROCKETT, Falls City, Nebr. Filed Oct. 23, 1897. Serial No. 656,208. (No model.)

Claim.—1. A cutting apparatus, having a handle composed of two members mounted to move toward and from each other, each member terminating in a flat jaw, arranged with their faces in parallel planes, the jaws being capable of grasping between them the stem of a plant, and one of the jaws having at its upper edge an outwardly-bent flange, and the other of the jaws having at its lower edge an outwardly-bent flange and at its upper edge a slot extending horizontally therein, and a cutter proper or blade secured rigidly on the outwardly-bent flange at the upper edge of the first-named jaw, said cutter or blade extending horizontally toward the other jaw and having an arm normally projecting over the said other jaw and through the slot in the upper edge thereof, the free end of said arm carrying a pin to limit the movement of the jaws away from each other.



2. A cutting apparatus, having a handle formed of two members movable toward and from each other, each member terminating at its free end in a jaw and the jaws having flat faces in parallel planes, between which faces the stems of plants may be engaged and held, one of the jaws having in its upper edge a horizontally-extending slot, and a cutter proper or blade secured to the other jaw and horizontally disposed so as to engage the upper edge of the jaw with the slot, the cutter or blade having a horizontally-projecting arm extending over the upper edge of the jaw with the slot and through the slot, the end of the arm having a pin to limit the movement of the jaws away from each other.

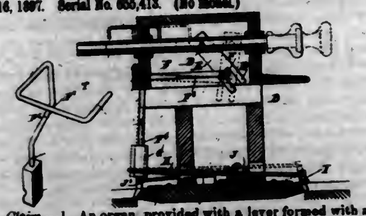
605,401. BOX-FASTENER. CHESTER M. CUNNINGHAM, Peora, W. Va. Filed July 26, 1897. Serial No. 645,922. (No model.)



Claim.—In a fastener for crates, the combination with the cover of the bolt 3, mounted in an aperture in a cross-strip thereof, the free end of said bolt being reduced and a notch formed therein, of the cross-strip of the crate, the casing secured in a recess in the under side of said cross-strip of the crate, the spring-actuated bolt in said casing, the free end of which bolt is disposed in the path of the hooked end of bolt 3, and designed to engage with said hooked end, of the pin 12 secured to the head of the bolt extending through a slot in the casing, and the rotary screw 14 fastened at its lower end to the casing, and the nut 15 carried on the upper end thereof and countersunk in the cross-strip of the crate, as shown and described.

605,402. STAY AND FASTENER. PARLEY A. DAILEY, Brooklyn, N. Y. Filed Mar. 14, 1898. Serial No. 673,185. (No model.)

Claim.—A stay and fastener consisting of the member C formed of longitudinally-extending sections D pivoted together at their adjacent overlapped ends, said sections each having on the lower end of its outer edge an integral eye *d*, a similar eye on the upper end of the upper section D; the eyes *d* intermediate the upper and lower members D being located in transverse alinement with the pivot-points of the members D, and the mating non-sectional member B provided with a series of fastenings in transverse alinement with said pivots and eyes and each comprising a transverse plate *a* on the outer side of said member and having at its outer end a transverse tongue *c* to project inwardly through an eye *d*, and a longer spring-plate *b* at the under side of said member and extending at its free end across the end of tongue *c*; said plates *a*, *b* being riveted together through the member B; substantially as described.



605,403. DENTAL BRIDGEWORK. CHARLES A. DAVIS, Pasadena, and EMORY L. TOWNSEND, Los Angeles, Cal.; said Townsend assignor to said Davis. Filed Nov. 9, 1897. Serial No. 657,866. (No model.)

Claim.—1. In dental bridgework, the bridge, the integrally-formed sockets thereon, a corrugated pin integral with the base of each socket, and a double-ended pin extending through the base of one of the said sockets, combined with the crowns fitted in said sockets and means for holding same on the socket-pins, as set forth.

2. In dental bridgework, the bridge made up of a series of sockets, integral corrugated and shouldered pins, one in each socket, one of the sockets being double with a common base and a double-ended pin extending through the said base thereof, combined with crowns secured as shown and described.

605,404. ORGAN. JOHN E. DAVIS, Washington, N. J. Filed Oct. 16, 1897. Serial No. 655,413. (No model.)

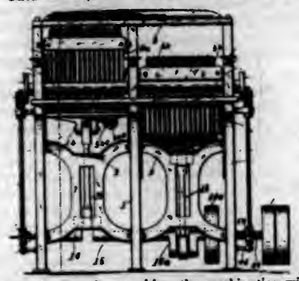
Claim.—1. An organ, provided with a lever formed with a pivot portion, and arms extending therefrom and at angles to each other, one of said arms having a bent portion extending parallel and in alinement with said pivot portion and arranged for connection with the actuating part, and the other arm being formed with a bend by which it is brought in line with the center of the pivot portion, said latter arm being arranged for connection with the part to be actuated, as set forth.

2. In an organ, the herein-described lever formed with a transversely-extending pivot portion held to rotate on its longitudinal axis in a bearing in the organ, an arm extending from one end of said pivot portion and at an angle thereto, said arm having its end bent parallel and in alinement with the pivot portion and by which it is connected with the actuating part, and a second arm extending from the opposite end of said pivot portion and at an angle thereto, said second arm being formed with a bend by which it is brought in line with the center of the pivot portion and being arranged for connection with the part to be actuated, as set forth.

3. In an organ, the combination with a frame and a stop fitted in said frame and having a link pivoted thereon, of a lever formed of a single piece of wire bent to form a transverse pivot portion mounted to rotate on its longitudinal axis in a bearing in said frame and having its center in line with said link, and two arms extending in opposite directions from the ends of said pivot portion and at an angle thereto, one of said arms being provided with a pin extending parallel with said pivot portion and arranged for connection with said link, and the other arm having its end bent in line with the center of said pivot portion and arranged for connection with the part to be actuated, as set forth.

605,405. WATER-JACKET FOR CYLINDERS OF ENGINES. WILLIAM F. DAVIS, Waterloo, Iowa, assignor to the Davis Gasoline Engine Works Company, same place. Filed May 7, 1897. Serial No. 636,519. (No model.)

Claim.—1. A gas-engine the cylinder whereof is provided at its ends with raised annular ribs or flanges, and at its inner end with a



raised part extending beyond the adjacent rib or flange, a jacket resting upon said flanges and having beveled ends terminating inside the cylinder-head and said raised part, packing-rings encircling said flanges of the cylinder and bearing against the beveled ends of the jacket, and a cylinder-head having its face abutting against the packing-ring that rests upon the flange at the outer end of the cylinder, substantially as described.

2. In an engine the combination with a cylinder provided at its ends with raised annular ribs or flanges and at its front end with a cylinder-head and having a raised shoulder adjacent the inner annular rib or flange, of a jacket formed of longitudinal sections shorter than the space between said raised shoulder and the cylinder-head, packing-rings encircling said ribs or flanges of the cylinder and against which the end portions of said jacket-sections bear and means for clamping said sections securely against said packing-rings and together whereby water-tight joints are formed at the ends of the jacket-sections and whereby the jacket-sections can be removed without disturbing the remaining parts, substantially as described.

3. In an engine the combination with a cylinder provided at its ends with suitable raised annular ribs or flanges, of a jacket formed of longitudinal sections having beveled ends, packing-rings encircling said flanges of the cylinder and bearing against the beveled ends of said jacket-sections and bolts for clamping said jacket-sections against said ring, substantially as described.

4. In an engine the combination of a cylinder provided upon its exterior with raised annular ribs or flanges and at its inner end with a raised part adjacent the corresponding annular rib or flange, a jacket formed of longitudinal sections having beveled ends terminating inside the cylinder-head and inside said raised part, said jacket-sections being also formed with grooved opposing edges, packing-rings encircling said flanges or ribs of the cylinder and bearing against the beveled ends of the jacket-sections, a cylinder-head having its face abutting against the packing-ring that rests against the flange at the outer end of the cylinder and. means for clamping said jacket-sections upon said packing-rings, substantially as described.

605,406. SAWING-MACHINE. LORENZ A. DEUTHER, Buffalo, N. Y. Filed June 28, 1897. Serial No. 642,575. (No model.)

Claim.—1. In a sawing-machine, the combination with the supporting-frame and the reciprocating saws, of a supplementary circular saw located behind the reciprocating saws for removing the sawdust between the side edges of the slats as they come from the reciprocating saws, as set forth.

2. In a sawing-machine, the combination with the frame, the reciprocating saws and the saw-table, provided with an opening located at the rear of the reciprocating saws, of a shaft mounted in said table and passing through said opening, and one or more circular saws adjustably supported on said shaft to remove the caked sawdust from between the slats as they come from the reciprocating saws, as set forth.

3. In a sawing-machine, the combination with the frame, the reciprocating saws and the saw-table, provided with an opening at the rear of the reciprocating saws, of a shaft mounted in the opening in said table and passing through said opening and one or more circular saws, adjustably supported on said shaft, said saws being provided with a series of slots or openings and having the side edges of said slots slightly offset or bent alternately to each side to afford means to remove the sawdust and smooth the side edges of the slats as they come from the reciprocating saws, as set forth.

4. In a sawing-machine, the combination with the reciprocating saws and the supporting saw-gates, of a series of spacing-plates placed between the saws, each provided with a top edge inclining diagonally downwardly toward the front and terminating in a projecting nose, and a rear depression or dovetail, a supporting portion fitting in said depression or dovetail, a cross-bar provided with a groove fitting over said nose and a screw device for rigidly securing said portion and cross-bar to the saw-gates, as set forth.

5. In a sawing-machine, the combination with the supporting-frame, provided with a slideway portion and table, of a saw-gate, mounted in said slideway and supporting a gang of reciprocating saws, a circular saw mounted in the table at the rear of the reciprocating saws, to remove the sawdust from between the slats as they come from the reciprocating saws, and an operating-shaft in connection with the saw-gate and the circular saw, as set forth.

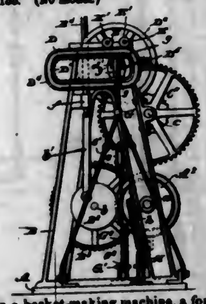
6. In a sawing-machine, the combination with the reciprocating saws and the supporting saw-gates, of a series of spacing-plates placed between the saws, each provided with a depression and a projecting nose, a supporting portion fitting in said depression, a cross-bar provided with a groove fitting over said nose and screw means for rigidly securing said portion and cross-bar to the saw-gates, as set forth.

7. In a double sawing-machine, the combination of the double frame, two saw-gates mounted in slideways in said frame, a series of reciprocating saws supported in each gate, a driving-shaft, a cam at each end thereof, two cranks extending at diametrically opposite directions from said shaft, two rods each pivotally connected at its lower end to one of the cranks and at its upper end to one of the saw-gates, feed-rollers provided with crown-wheels, and rods having their lower ends provided with gear-wheels engaging with the cams on the driving-shaft, and their upper ends with pinions engaging with the crown-wheels on the feed-rollers, as set forth.

605,407. COUNTERSINKER. CHARLES DUNAW, Jr., Cheboygan, Mich., assignor of one-half to Isaac Piercy, same place. Filed Dec. 23, 1897. Serial No. 663,217. (No model.)

Claim.—1. A countersinking-tool comprising relatively-adjustable members, adapted to have their end portions fitted within the bore or opening to be countersunk, means for securing the members in an adjusted position, and a bit applied to and projecting laterally from one of the members a short distance from its active extremity, substantially as set forth.

2. A countersinking-tool comprising relatively-adjustable members having their active ends reduced to readily enter the bore to be countersunk, said tool having a shank at its opposite end to be fitted into a bit-stock, means for holding the members in an adjusted position, and a bit applied to a member a short distance from its extremity, substantially as set forth.



3. A countersinking-tool comprising pivoted members adapted to have their end portions fitted within the bore or opening to be countersunk, one of the members having a shank to admit of the tool being fitted to a bit-stock, means for holding the members at the required distance apart, and a bit applied to and projecting laterally from a member a short distance from its extremity, substantially as set forth.

4. A countersinking-tool comprising a member having a head provided with a shank to be fitted into a bit-stock, and having a slot, a second member pivoted within the slotted head, both members adapted to have their end portions fitted within the bore or opening to be countersunk, means for holding the members at the required distance apart, and a bit applied to and projecting outwardly from a side of a member a short distance from its active extremity, substantially as set forth.

5. In a countersinking-tool, the combination of members relatively adjustable, and adapted to have their end portions fitted within the bore or opening to be countersunk, one of the members having a transverse opening a short distance from its active end, a bit having a substantially horizontal and vertical cutting edge and fitted into the opening of the member to which it is secured, and means for fastening the bit in position, substantially as described.

6. The herein-described countersinking-tool, comprising a member having a slotted head formed with a shank to be fitted into a bit-stock, a second member pivoted within the slotted head, the extremities of the members being adapted to be fitted within the bore or opening to be countersunk, a curved bar secured to one of the members and passing loosely through an opening in the opposite member, a set-screw for securing the curved bar within the opening and holding the members at the required distance apart, and a bit having an approximately horizontal and a vertical cutting edge and having adjustable connection with and projecting laterally from one of the members a short distance from its active end, substantially as set forth.

605,408. BASKET-MAKING MACHINE. JOHN R. DURHAM and JOSEPH R. DEVINE, Douglas, Mich., assignors to Elmer E. Weed, D. Milton Gerber, and Cornelius Gerber, same place. Filed July 19, 1897. Serial No. 645,123. (No model.)

Claim.—1. In a basket-making machine, a form having internal racks rotatably mounted beneath a stapling-machine, a shaft having pinions which engage with the racks of the form and means for holding the form in engagement with said pinions, substantially as set forth.

2. In a basket-making machine, a form having racks, a recess in the form, a plate engaging with said recess and a shaft which passes through the plate, said shaft having pinions for actuating the form, substantially as shown.

3. In a basket-making machine, the combination with a form having parallel sides and rounded corners, a shaft having pinions for engagement with racks which project from the inner side of the form; together with a retaining-plate upon which the form moves and a stapling-machine mounted above the form, substantially as shown.

4. In a basket-making machine, a form upon which the parts of the basket are assembled, a stapling-machine mounted above the form and in gear therewith, the gear including mechanism for imparting to the form an intermittent movement between the strokes of the staple drivers, the range of movement of the form being alternately horizontal beneath the staple-drivers and in quadrant arcs in turning the corners thereof.

5. In a basket-making machine, a form having internal racks, a recess and circumferential flange, a plate carried by a support said plate engaging the recess, a shaft which passes through the plate and is provided with pinions which engage with the racks so that the plate and pinions on the shaft provide a support for the form, a pair of rollers mounted so as to engage with the flange and a stapling-machine mounted above the form, substantially as shown.

6. In a basket-making machine, the combination with a stapling-machine, of a form mounted beneath the same and in gear therewith, means for supporting and actuating the form so as to impart thereto a longitudinal movement for the length of each side and an intermediate turning or rotative movement at the corners.

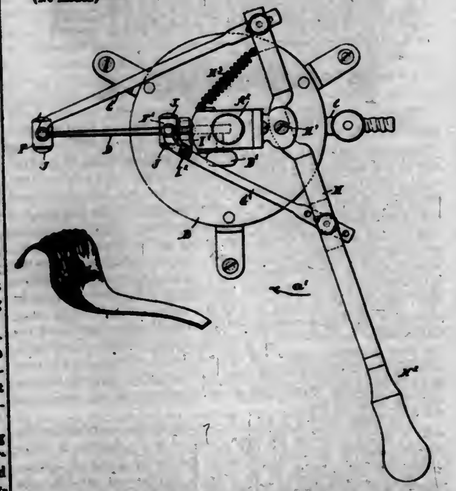
7. In a basket-making machine the combination with a form and means for moving said form longitudinally turning the same and again moving the opposite side longitudinally, of rollers carried by the frame and adapted to engage with said form and a pair of rollers carried by a pivoted support for engagement with the bottom of a basket when placed on the form; together with a stapling-machine operating above said form and in conjunction therewith.

8. In a basket-making machine, the combination with a stapling-machine and driving-gear therefor, of a basket form in gear with the mechanism for driving the stapling-machine, the form being so supported and geared that there will be imparted thereto an intermittent movement rotatably about its four corners alternately with a movement horizontally for the length of its sides and ends.

9. In a basket-making machine, the combination with driving mechanism having means or devices for imparting an intermittently-rotary movement to a shaft, a basket-form having a horizontal and partially-rotary movement imparted thereto from the intermittently-rotating shaft, a shaft in gear with the driven shaft and provided with a pitman for imparting a reciprocating movement to a stapling-machine, a foot-lever and means for holding the foot-lever raised so that the driving-shaft will be held against movement with the driving-pulley free to turn thereon, the brake being released when the driving-pulley is in operative engagement therewith by the depression of the foot-lever, substantially as shown and for the purpose set forth.

10. In a basket-making machine a frame or support having a plate, a form having a recess with which said plate engages, a rotary shaft having a pinion, the form having inward-projecting racks for engagement with the pinion on the shaft so that the form will be given when the shaft is rotated a longitudinal movement and a swinging movement on different axes; together with a stapling-machine having hoop-rollers and hoop-guides, for the purpose set forth.

11. In a basket-making machine, the combination with a form, a stapling-machine having staple-drivers positioned above the same, of a support for a shaft carried by the stapling-machine so as to project beyond the staple-drivers thereof, hoop rollers and guides carried by said shaft and a spring for forcing the shaft toward the form, for the purpose set forth.



12. In a basket-making machine, the combination with a form, of a stapling-machine mounted on a support above the form so that the staple-drivers will project over the form, a tube carried by the frame of the stapling-machine and positioned between the staple-drivers, a shaft-spring actuated in one direction, a cross-bar attached to the shaft and provided with rollers, said cross-bar also carrying a plate with guide-pins, substantially as shown and for the purpose set forth.

13. In a basket-making machine, the combination with a frame having shaft-bearings as shown in which are journaled shafts *a b e* and *d*, pitmen attached to the shaft *a* one for imparting a reciprocating motion to the staple-drivers of a stapling-machine the other having a pawl for engagement with a ratchet-wheel to drive the shaft *c*, a gear-wheel on the shaft *c* which meshes with a pinion on the shaft *d*, and a basket-form in gear with the pinions on the shaft *d*, the parts being organized, substantially as shown and for the purpose set forth.

14. In a basket-making machine, a form upon which the parts of the basket are manually assembled, mechanism for imparting to the form a step-by-step movement longitudinally and a movement rotatably about the corners of the form, a guide or plate upon which the form moves and turns, a pair of guide-rollers in direct engagement with the form one on each side of the longitudinal center of the driving-shaft which imparts movement to the form, substantially as set forth.

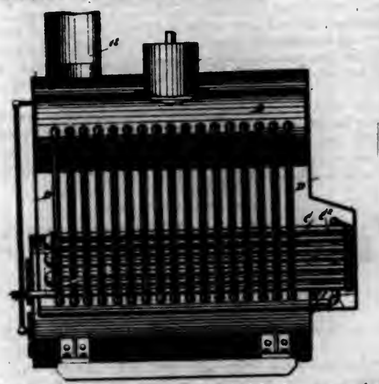
15. In a basket-making machine, the combination with a form having its bottom-receiving portion disposed in a vertical plane, of an arm movable to and from the form, a plate and rollers carried by the arm so that they may engage with the bottom board of the basket, substantially as set forth.

605,409. ARTIFICIAL-FLOWER-CRIMPING MACHINE. LUCIEN RIBERY, New York, N. Y. Filed Jan. 28, 1896. Serial No. 668,297. (No model.)

Claim.—1. A crimping-press, provided with bars for holding the blanks loosely between them, and heads on said bars, for pressing the blanks endwise while held between the bars, substantially as shown and described.

2. A crimping-press, provided with bars, one of which is movable relatively to the other to hold the blanks loosely between the bars, and heads held on said bars, for pressing the blanks endwise, substantially as shown and described.

3. A crimping-press, provided with a fixed bar, a pivoted bar adapted to swing toward and from the fixed bar to hold the blanks between the bars, heads mounted to slide on the bars to press the blanks endwise, and means for imparting a swinging motion to the pivoted bar, substantially as shown and described.

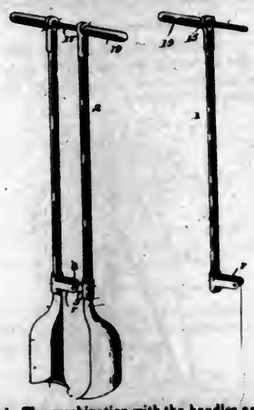


4. A crimping-press, provided with a fixed bar, a pivoted bar adapted to swing toward and from the fixed bar to hold the blanks between the bars, heads mounted to slide on the bars to press the blanks endwise, means for imparting a swinging motion to the pivoted bar, and an adjusting device for regulating the position of the movable bar relatively to the fixed bar, substantially as shown and described.

5. A crimping-press, provided with bars, one of which is movable relatively to the other to hold the blanks loosely between the bars, heads held on said bars, for pressing the blanks endwise, a lever under the control of the operator, and links connecting said lever with the said heads to move the latter simultaneously toward or from each other upon imparting a swinging motion to the lever, substantially as shown and described.

6. A crimping-press, provided with bars, one of which is movable relatively to the other to hold the blanks loosely between the bars, heads held on said bars, for pressing the blanks endwise, a post carrying said bars, and means for heating the post and bars carried thereby, substantially as shown and described.

7. A crimping-press, provided with crimping-bars, heads held movable thereon, and jaws carried by the said heads and riding loosely between the bars, substantially as shown and described.

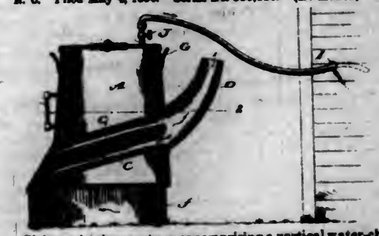


605,410. BOILER. BENJAMIN P. BERRY, Kennebunk, Me. Filed Jan. 22, 1898. Serial No. 667,562. (No model.)

Claim.—1. A boiler having a cylindrical fire-box, a water-jacket encircling the fire-box, a casing inclosing the upper portion of the fire-box and extending upward above the same, a bridge at the rear end of the fire-box and leading into an extension at the rear of the casing, a coil of pipe extending around the fire-box and into the said extension of the casing so as to pass rearward of the fire-box, the coil of pipe communicating with the water-jacket, a boiler proper located in the upper portion of the casing and having a steam-dome projected through the casing, upright or stand pipes running from the water-jacket of the fire-box to, and communicating with the boiler proper, the said upright or stand pipes being divided into two sets located respectively at each side of the boiler proper and fire-box, secondary stand-pipes communicating with the upper portion of the water-jacket and extending upwardly to, and having communication with the boiler proper, and two additional coils of pipes located between the secondary stand-pipes and extending between the fire-box and the boiler proper and communicating with the latter and with the water-jacket.

2. A boiler, having a fire-box, a water-jacket surrounding the same, a casing inclosing the upper portion of the fire-box, a boiler proper located in the upper portion of the casing, a coil of pipe extending around the sides of the fire-box and around the rear end thereof, and communicating with the water-jacket, stand-pipes located at each side of the fire-box, and extending upwardly to, and communicating with the boiler proper, the stand-pipes also communicating with the water-jacket, and coils of pipes located between the boiler proper and the fire-box and also between the stand-pipes, the said coils of pipes communicating with the water-jacket and with the boiler proper.

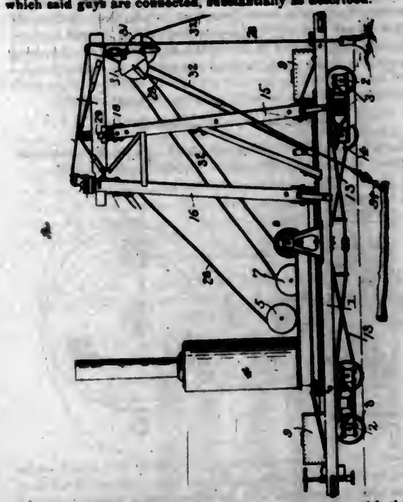
605,411. POST-AUGER. JAMES EVANS, Davis City, Nebr. Filed June 18, 1897. Serial No. 641,214. (No model.)



Claim.—1. The combination with the handles and screw-sleeves at their lower ends having lateral arms, and an adjustable pivot connecting them, of shells having screw-threaded shanks engaging sockets in said sleeves, and means adjustably connecting the opposite ends of said handles, as set forth.

2. The combination with the handles pivoted together near their lower ends and the shells carried by said handles, of hollow handles projecting laterally from the upper ends of the handles one of which is interiorly threaded, a sleeve movably mounted in the other handle and a screw-rod entering said sleeve at one end and the other end engaging the threads of the other handle, substantially as specified.

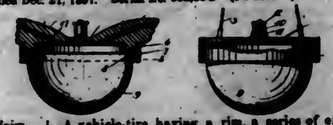
3. The combination with the handles pivoted together at their lower ends and the shells carried thereby, of hollow grip-handles projecting laterally from the upper ends of the handles and one of which is interiorly threaded a nut held in the inner end thereof, a sleeve movably mounted in the other handle and a screw-rod entering the sleeve at one end and the other end engaging said nut and the threads of the other grip-handle, all substantially as shown and described.



605,412. TOBACCO-STEAMER. ANDREW J. FAIR, Walnut Cove, N. C. Filed May 4, 1896. Serial No. 590,110. (No model.)

Claim.—A tobacco-steamer comprising a vertical water-chamber, a depending casing to support the water-chamber and form a fire-box beneath the same, a stack located upon one side of said chamber, a series of diagonally-extending flues in the lower part of said chamber and communicating with the fire-box and stack, and a steam-conducting pipe extending from the upper part of said chamber, substantially as and for the purposes set forth.

605,413. LOG-HAULING LOCOMOTIVE. WILLIAM A. FLETCHER, Beaumont, Tex. Filed Oct. 23, 1897. Serial No. 656,043. (No model.)



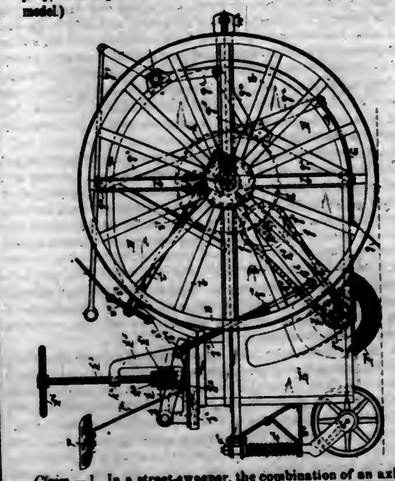
Claim.—1. In a log-hauling locomotive, the combination with the platform, the connected shears and the crane, of the hollow pin secured to the rear shears, passing through said crane, the sheaves connected with said shears above and below the crane, the sheaves at the front of the crane at an angle to the sheaves connected with the shears, the guys passing around the sheaves connected with the shears at opposite sides thereof and through the hollow pin, and around the sheaves connected with the cranes, and the hauling-chains, substantially as described.

2. In a log-hauling locomotive, the combination with the platform, the connected shears, the crane, the hollow pivot-pin passing through said crane, the grooved sheaves connected above said shears above and below the crane and in different vertical planes, the sheaves at the front of the crane at an angle horizontally to the sheaves of the shears, the guys and the drums to which they are secured, of the sheaves connected with the under side of the crane at the front end thereof, the hauling-chains, and the drums with which they are connected, substantially as described.

3. In a log-hauling locomotive, the combination with the platform, the axle provided with sprocket-pinions, the sprocket-chains, the transverse shaft, the sprocket-wheels thereon, the guy-rope drums mounted on a common shaft, the hauling-rope drums located in rear thereof and means for operating the same, of the connected shears, the crane, the hollow pin secured to the rear shears, passing through said crane, the sheaves connected with said shears above and below the crane, the sheaves at the front of the crane at an angle to the sheaves connected with the shears, the guys passing around the sheaves connected with the shears at opposite sides thereof and through the hollow pin and around the sheaves connected with the cranes, and the hauling-chains, substantially as described.

605,414. VEHICLE-TIRE. HERMAN A. FOUTHUS, Auburn, N. Y. Filed Dec. 21, 1897. Serial No. 662,954. (No model.)

Claim.—1. A vehicle-tire having a rim, a series of expansible bulbs, means for independently securing the bulbs to the rim, and a series of passages formed in the rim and connecting the bulbs with each other, one of said bulbs being in communication with a nipple, whereby all the bulbs may be inflated, substantially as described.



2. A vehicle-tire having a rim provided with a series of ridges or enlargements each having a passage extending through it, and a series of inflatable bulbs independently secured to the said rim, the passages in the said ridges or enlargements respectively connecting with adjacent bulbs, whereby the bulbs are all placed in communication with each other, substantially as set forth.

3. A vehicle-tire having a rim provided on its outer face with a series of annular ribs, a clamping-band screwing over each annular rib, and a series of inflatable bulbs provided at their base edges with beads arranged to be held between the respective ribs and clamping-bands, substantially as specified.

4. A vehicle-tire having a rim provided on its outer face with a series of annular ribs exteriorly threaded, expansible bulbs provided at their base edges with beads, clamping-rings adapted to screw on the said annular ribs and having inwardly projected or contracted portions at their outer edges serving to hold the beads against the said annular ribs, the said bulbs being in communication with each other, substantially as set forth.

5. A vehicle-tire provided with a rim, a series of expansible bulbs, means for securing said bulbs on the outer surface of the rim, the said rim being provided on its inner face with a series of equidistant arc-shaped enlargements leading between the contiguous bulbs, and each having a passage forming a communication between the interior of contiguous bulbs, respectively, substantially as described.

605,415. STREET-SWEEPER. WILLIAM FRAHS, Allegheny, Pa., assignor, by mesne assignments, to the Improved Street Sweeper Company, Pittsburg, Pa. Filed Nov. 27, 1897. Serial No. 659,804. (No model.)

Claim.—1. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a casing supported around the axle, a tank or dirt-receptacle rigidly secured to the axle, a conveyer between the casing and the tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of the axle, connections from the driving-wheels to the rotatable broom, and gearing mechanism connected to the driving wheels and to gear-wheels loosely mounted around the axle and rigidly connected to the conveyer, substantially as and for the purposes set forth.

2. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a casing supported around the axle, a tank or dirt-receptacle rigidly secured to the axle, a conveyer between the casing and the tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of the axle, connections from the driving-wheels to the rotatable broom, gearing mechanism connected to the driving-wheels and adapted to operate gear-wheels loosely mounted around the axle, and ratchet-wheels having pawls engaging therewith connected to said gear-wheels and rigidly connected to the conveyer or frame, substantially as and for the purposes set forth.

3. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a casing supported around the axle, a tank or dirt-receptacle rigidly secured to the axle, a conveyer between the casing and tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of the axle, connections from the driving-wheels to the rotatable broom, gear-wheels connected to the driving-wheels and meshing with pinions mounted on shafts supported on said casing, pinions on said shafts and meshing with gear-wheels loosely mounted around the axle, and ratchet-wheels having pawls engaging therewith connected to said last-named gear-wheels and rigidly connected to the conveyer, substantially as and for the purposes set forth.

4. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a casing supported around the axle, a tank or dirt-receptacle rigidly secured to said axle, a conveyer-frame between the casing and tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of said axles, connections from the driving-wheels to the broom, a cross-bar supported by and in front of said casing, and bars removably secured to said cross-bar and having collars thereon rigidly secured to the axle for dumping and holding the tank or dirt-receptacle in place, substantially as set forth.

5. In a street-sweeper, the combination of an axle, supporting

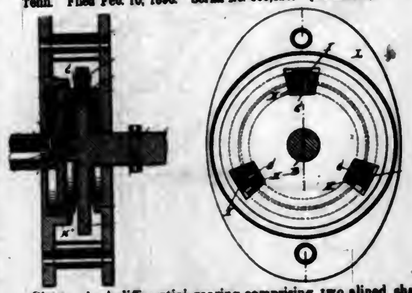
and driving wheels loosely mounted around the axle, a casing supported around the axle, a tank or dirt-receptacle rigidly secured to said axle, a conveyer-frame between the casing and tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of the axle, connections from the driving-wheels to the broom, a cross-bar supported by and in front of said casing, bars removably secured to said cross-bar having collars thereon rigidly secured to the axle, and bolts removably connected to the cross-bars and bars for dumping and holding the tank or dirt-receptacle in place, substantially as set forth.

6. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a casing supported around the axle, a tank or dirt-receptacle rigidly secured to said axle, a conveyer-frame between the casing and tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of the axle, connections from the driving-wheels to the broom, a cross-bar supported by and in front of said casing, bars removably secured to said cross-bar having collars thereon rigidly secured to the axle, slots in said cross-bars, and bolts removably connected to the cross-bars and bars having elongated heads thereon engaging the said slots in the cross-bars for dumping and holding the tank or dirt-receptacle in place, substantially as set forth.

7. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a casing supported around the axle, a tank or dirt-receptacle rigidly secured to said axle, a conveyer-frame between the casing and tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of the axle, connections from the driving-wheels to the broom, a cross-bar supported by and in front of said casing, bars removably secured to said cross-bar having collars thereon rigidly secured to the axle, bolts removably connected to the cross-bar and bars having elongated heads thereon engaging with said slots in the cross-bar, and wrench-nuts engaging the said bolts for dumping and holding the tank or dirt-receptacle in place, substantially as set forth.

8. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a rotatable broom mounted in the rear of the axle, connections from the driving-wheels to the broom, and adjustable spring-rods secured to the said rotatable broom and pivotally swiveled in sleeves pivoted in arms secured to a shaft supported above the rotatable broom, substantially as set forth.

9. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a rotatable broom mounted in the rear of the axle, connections from the driving-wheels to the broom, adjustable spring-rods secured to said broom and pivotally swiveled in arms secured to a shaft supported above the broom, and a worm gear-wheel on said shaft meshing with a worm on an upright shaft having an operating-wheel thereon for raising and lowering the broom, substantially as set forth.



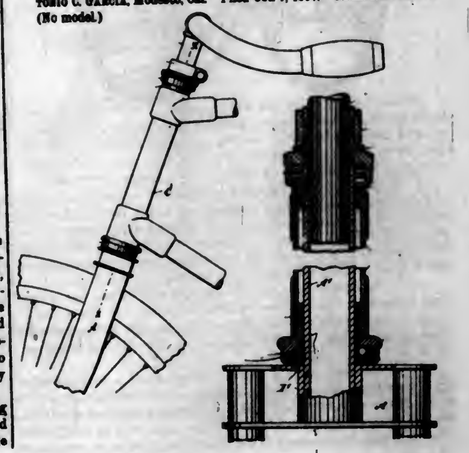
10. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a casing supported around the axle and provided with an opening in the bottom thereof, a tank or dirt-receptacle rigidly secured to said axle, a conveyer-frame between the casing and tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of the axle, connections from the driving-wheels to the broom, means on said axle for dumping and holding the tank in place, and a removable door pivoted to said casing and fitting over the opening in the bottom of the casing to allow the tank to be emptied, substantially as set forth.

11. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a casing supported around the axle and provided with an opening in the bottom thereof, a tank or dirt-receptacle rigidly secured to said axle, a conveyer-frame between the casing and tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of the axle, connections from the driving-wheels to the broom, means on said axle for dumping and holding the tank in place, a removable door pivoted to said casing and fitting over the opening in the bottom of the casing to allow the tank to be emptied, and means connected to said door for raising and lowering the same, substantially as set forth.

12. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle, a casing supported around the axle and provided with an opening in the bottom thereof, a tank or dirt-receptacle rigidly secured to said axle, a conveyer-frame between the casing and tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of the axle, connections from the driving-wheels to the broom, means on said axle for dumping and holding the tank in place, a removable door pivoted to said casing and fitting over the opening in the bottom of the casing to allow the tank to be emptied, and a series of levers pivoted to the door and casing for raising and lowering the door, substantially as set forth

13. In a street-sweeper, the combination of an axle, supporting and driving wheels loosely mounted around the axle and provided with an opening in the bottom thereof, a tank or dirt-receptacle rigidly secured to said axle, a conveyer-frame between the casing and tank carrying buckets thereon, a rotatable broom adjustably mounted in the rear of said axle, connections from the driving-wheels to the broom, means on said axle for dumping and holding the tank in place, a removable door pivoted to said casing and fitting over the opening in the bottom of the casing to allow the tank to be emptied, and a flexible apron secured to the rear end of said removable door to direct the sweepings into the buckets, substantially as set forth.

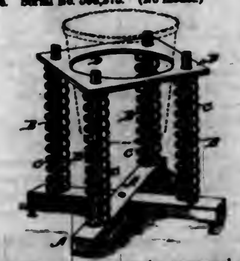
605,416. DIFFERENTIAL GEARING. DANIEL FYFE, Covington, Tenn. Filed Feb. 10, 1898. Serial No. 669,836. (No model.)



Claim.—1. A differential gearing comprising two alined shafts arranged to rotate independently of each other, and one of which is provided with a gear-wheel and the other with a support carrying pinions, one of which pinions is in mesh with said gear-wheel, and fixed gear-wheels of different diameters, adapted to be alternately engaged by said pinions, substantially as shown and described.

2. A differential gearing comprising two alined shafts arranged to rotate independently of each other, and yieldingly connected with each other to permit of shifting the shafts longitudinally, one of the shafts being provided with a gear-wheel and the other with a support, pinions journaled in said support, one of said pinions being in mesh with the gear-wheel on the shaft, and fixed gear-wheels of different diameters, adapted to be engaged alternately by said pinions, substantially as shown and described.

3. A differential gearing comprising two alined shafts arranged to rotate independently of each other, and yieldingly connected with each other to permit of shifting the shafts longitudinally, one of the shafts being provided with a gear-wheel and the other with a support, pinions journaled in said support one of said pinions being in mesh with the gear-wheel on the shaft, fixed gear-wheels of different diameters, adapted to be engaged alternately by said pinions, and means for moving the shafts longitudinally, to bring said pinions in mesh with either of said fixed gear-wheels, one of said pinions, however, remaining in mesh at all times with the gear-wheel on the shaft, substantially as shown and described.



605,417. AUTOMATIC STEERING-HEAD FOR BICYCLES. ANTONIO C. GARCIA, Modesto, Cal. Filed Oct. 7, 1897. Serial No. 654,358. (No model.)

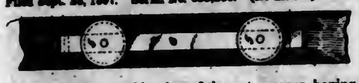
Claim.—1. A bearing for the steering-head of a bicycle, consisting of a plate having a series of radially-extending grooves with inclined sides in its face, a plate having corresponding recesses and balls therein adapted to normally rest in said grooves, and an interposed absorbent washer apertured to receive the balls, said plates being connected respectively to the fork and frame of the bicycle, substantially as described.

2. A steering-head for bicycles, comprising a plate attached to the fork at the lower end of the head, and having hemispherical recesses in its upper surface and balls in said recesses projecting above the surface of the plate, a cup embracing said plate and attached to the frame, the bottom of said cup having radially-extending grooves with sloping sides adapted to receive said balls, a cup attached to the steering-bar and having downwardly-projecting flanges, and a spiral spring within said cup and engaging the upper end of the frame-head, substantially as described.

605,418. EGG-CARRIER. CHARLES GOSEY, Viola, Idaho. Filed July 6, 1896. Serial No. 598,575. (No model.)

Claim.—The improved egg-carrier composed of the cruciform base, four vertical posts set in the end portions thereof, coiled springs encircling the posts, the horizontal platform, having holes for reception of said posts, and provided with a large central opening for reception and support of an egg-basket, the upper portions of the posts projecting a considerable distance above the platform, as and for the purpose described.

605,419. FRUIT-PICKER. LEE S. HAGAN, Brewer, Me. Filed June 10, 1897. Serial No. 640,208. (No model.)

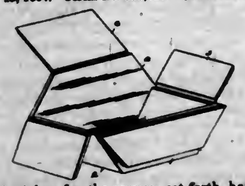


Claim.—1. A fruit-picker comprising a body portion made up of two sections substantially semicircular in cross-section, pivoted one to the other at points intermediate of their ends and provided with picking-fingers, and a delivery-tube made up of two sections substantially semicircular in cross-section, pivoted one to the other intermediate of their ends and pivoted respectively to the sections of the body portion, as and for the purpose set forth.

2. A fruit-picker comprising a body portion made up of two sections substantially semicircular in cross-section, pivoted one to the other at points intermediate of their ends, provided with picking-fingers, guides on said sections for holding them in alinement one with the other, a handle for operating said sections, and a delivery-tube made up of two sections, substantially semicircular in cross-section, pivoted to each other at a point intermediate of their ends and pivoted respectively to the sections of the body portion, as and for the purpose set forth.

3. A fruit-picker comprising a body portion made up of two sections substantially semicircular in cross section pivoted together at points intermediate of their ends, provided with picking-fingers at one end and with handles at their opposite ends, and a delivery-tube made up of two sections substantially semicircular in cross-section pivoted one to the other at points intermediate of their ends, and having their lower ends contracted and pivoted at their opposite ends respectively to the sections of the body portion.

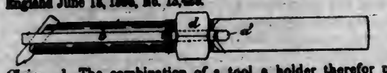
4. In a fruit-picker, the combination with tubular pivoted sides, of telescopic extensions thereto, held within said sides, guide-pieces on said extensions, clipping-fingers on the ends thereof, means for adjusting said extensions within said tubular sides, handles upon said sides, a delivery-tube comprising two sides approximately semicircular in cross-section pivoted together, flexible springs each joining one of said sides to one side of the telescopic body portion, guide-pieces carried on one of said sides and an extension thereon provided with cushioning material, substantially as shown and for the purpose set forth.



605,420. GATE-HINGE. JOHN R. HALDEMAN, Springfield, Mo. Filed Sept. 28, 1897. Serial No. 653,266. (No model.)

Claim.—1. The combination of the gate proper, having longitudinal guide-bars, with a vertical supporting pivot-bar or hanger, which is provided with parallel horizontal flanges having perforations arranged at diagonally opposite points, as and for the purpose specified.

2. The gate-supporting pivot-bar or hanger arranged vertically in a suitable fixed support, and having parallel, horizontal flanges provided with perforations arranged in diagonal relation, as shown and described for the purpose specified.

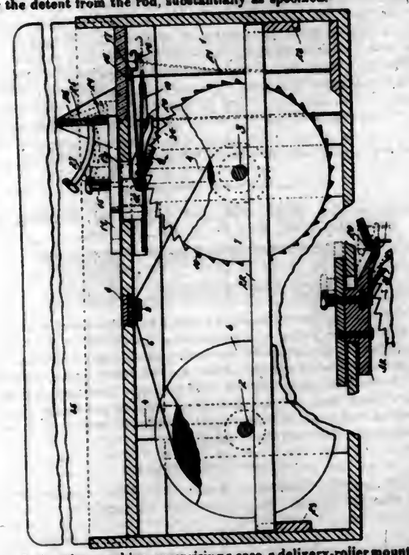


605,421. CIGAR-BOX. EUGENE F. HARBURG, Rochester, N. Y. Filed May 15, 1897. Serial No. 636,729. (No model.)

Claim.—1. A box for the purpose set forth, having hinged sections forming the upper part of the sides said hinged sections being inclined inwardly the upper part of the front and back being shaped to correspond thereto, said front having also a hinged section forming the upper part of the same, the box constructed with the hinged side and front sections, as described, having also a hinged lid, substantially as shown and described.

2. A box for the purpose set forth, having sides which are inclined outwardly from the bottom and then inwardly the upper sections being hinged to the lower sections, in connection with the front and back shaped at its ends to correspond with the inclinations of the sides, the front having an upper hinged section; together with a top or lid attached to the box so formed, substantially as shown and described.

605,422. TOOL AND HOLDER FOR USE IN CUTTING, BORING, AND SLOTTING METALS. WILLIAM H. HARDY, Hartlepool, England. Filed Dec. 28, 1897. Serial No. 664,083. (No model.) Patented in England June 18, 1896, No. 13,629.

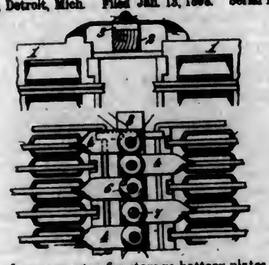


Claim.—1. The combination of a tool, a holder therefor provided with grooves in its end and sides, a clamp adapted to slide in the side grooves and means for operating said clamp to adjust the holder, substantially as described.

2. The combination of a tool, a holder therefor provided with a groove in one of its ends and with side grooves, said holder being also provided with screw-threads for a part of its length, a clamp provided with notches and a nut engaging said notches and said screw threads, substantially as described.

605,423. VOTING-MACHINE. ANDREW H. HART, Winchester, Ky. Filed Aug. 13, 1897. Serial No. 648,136. (No model.)

Claim.—1. A voting-machine, comprising a case, a delivery-roller and a take-up roller mounted in the case, a numbered tape extended between the rollers, a block movable in a slot in the top of the case, a dog mounted to swing on said block and adapted to engage with ratchet-teeth formed in a flange of the take-up roller, a resilient detent-strip extended from the block and having a hook end, a rod



over which said hook end is designed to engage, and means for lifting the detent from the rod, substantially as specified.

2. A voting-machine, comprising a case, a delivery-roller mounted in said case, a take-up roller mounted in the case, a plate arranged in the case below a sight-opening in the top of the case, a numbered tape extended between the rollers and over said plate, a block movable in a slot in the top of the case, a dog mounted to swing on said block and adapted to engage with ratchet-teeth formed on one of the flanges of the take-up roller, a resilient detent-plate extended forward of the block and having a hook end, a rod over which said hook end is designed to engage, a resilient lifting-strip extending from the block underneath the detent, means for raising said lifting-plate, and a spring for returning the block to its normal position, substantially as specified.

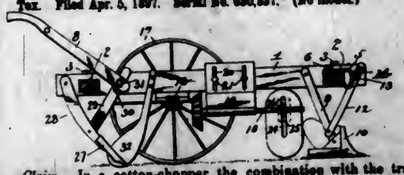
3. A voting-machine, comprising a case, a number of delivery-rollers in said case, a number of take-up rollers in said case, numbered tapes extended between feed and take-up rollers, a slide-block for operating each take-up roller, a spring-yielding detent extended from the block and adapted to engage with a bar extended across the case, a swinging bar engaging underneath the several detents, another sliding block, and a cam-finger extended from said other block and engaging with the swinging bar to lift the same and release the detents, substantially as specified.

605,424. CONNECTOR FOR STORAGE-BATTERY PLATES. GILBERT HART, Detroit, Mich. Filed Jan. 13, 1898. Serial No. 666,536. (No model.)

Claim.—1. In a connector for storage-battery plates, the combination of an insulating base-bar, a lead or metallic plate superimposed upon the said base-bar, connector-plates alternately extending in opposite directions and resting at one end upon the lead or metallic plate, and screws passing through the connector-plates and the superimposed lead or metallic plate into the insulating base-bar, substantially as described.

2 In a connector for storage-battery plates, the combination of an insulating base-bar, a lead or metallic plate superimposed upon said base-bar, connector-plates alternately extending in opposite directions and resting at one end upon the lead or metallic plate, washers arranged upon the ends of the connector-plates which rest on the lead or metallic plate, and screws passing through the washers, the connector-plates and the lead or metallic plate into the insulating base-bar, substantially as and for the purposes described.

605,425. COVER FOR MILK-CANS. ELMER E. HARVEY, Dolington, Pa. Filed Dec. 9, 1897. Serial No. 661,291. (No model.)

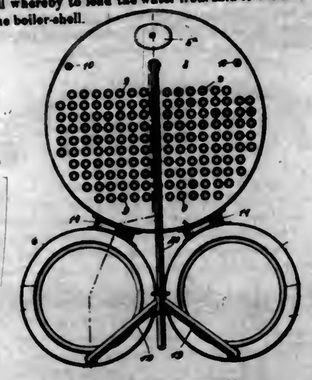


Claim.—1. A cover for milk-cans, the cover having a stopper or main portion with an orifice therein, two closures connected with each other and respectively capable of extending over said orifice, one of the closures being foraminated and the other being capable of effecting a hermetic sealing.

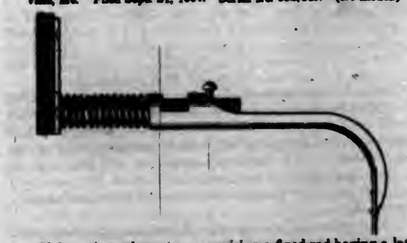
2. A cover for milk-cans, having a stopper or main portion with an orifice therein, a shield held above the stopper or main portion and supported thereon, and two closures joined to each other and capable of extending between the stopper or main portion and the shield, one of said closures being foraminated to ventilate the can and the other closure being capable of effecting a hermetic sealing of the can.

3. A cover for milk-cans, the cover having a stopper or main portion with an orifice in the top thereof, legs upon the stopper or main portion, a shield supported by the legs, and two interchangeable closures rigidly joined to each other by braces extending between them, the closures being each capable of covering the orifice of the stopper or main portion, one closure being capable of effecting a hermetic sealing and the other closure being foraminated to permit the ventilation of the can.

4. In a cover for milk-cans, the combination of a stopper or main portion having an orifice, two interchangeable closures rigidly connected with each other, and a spring attached to the stopper or main portion and capable of engaging the closures to hold them removably in position, one closure being foraminated to permit the ventilation of the can and the other closure being capable of effecting a hermetic sealing of the can.



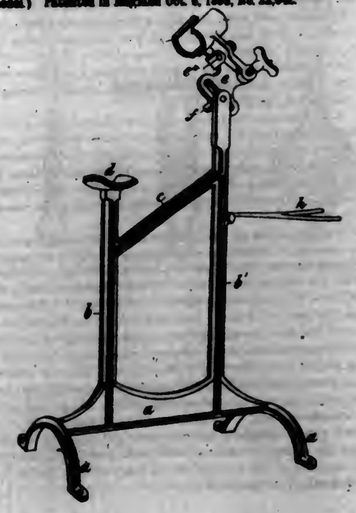
605,426. COTTON CHOPPER AND CULTIVATOR. JOSEPH J. HOLLAND, Edge, Tex., assignor of one-half to Henry Mitchell, Wheelock, Tex. Filed Apr. 5, 1897. Serial No. 630,897. (No model.)



Claim.—In a cotton-chopper, the combination with the transverse beams, the side beams one of which is laterally adjustable, the axle, the wheels, one of which is laterally adjustable, and the adjustable bevel-gear on said axle and means for adjusting the same, of the slotted plate, the set-screws for securing it to one of the side beams, the shaft journaled thereto, the bevel-gear at the rear end meshing with the adjustable bevel-gear, the choppers, at the front end of said shaft, formed with slots, the clamping-plates and the set-screws passing through said slots and through the clamping-plates, substantially as described.

605,427. STEAM-BOILER AND FURNACE THEREFOR. WILLIAM HOPKINS, Dubuque, Iowa. Filed Sept. 14, 1897. Serial No. 651,686. (No model.)

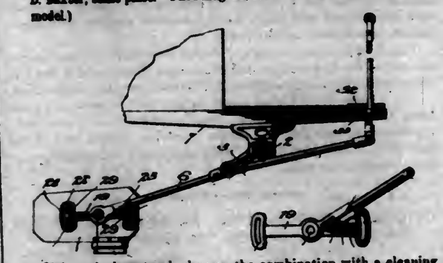
Claim.—A boiler having a cylindrical boiler-shell, a series of fire-tubes run through said shell, two exterior furnace-shells located beneath the boiler-shell and running parallel therewith and communicating therewith at each end, a fire-wall within each furnace-shell, the spaces inclosed by the front portions of the fire-walls serving as fire-boxes, means engaging said shells and forming a passage establishing communication between the fire-walls and the fire-tubes of the boiler-shell, and pipes passing respectively from the rear bottom portion of each furnace-shell upward to the upper portion of the boiler-shell whereby to lead the water from said lower rear portions back to the boiler-shell.



605,428. CARRIAGE-STEP. WILLIAM F. HOPKINS, Caruthersville, Mo. Filed Sept. 21, 1897. Serial No. 652,449. (No model.)

Claim.—A carriage-step comprising a fixed rod having a lateral projection, a shank formed with two downwardly-inclined cam-surfaces approaching each other at their adjacent ends, said shank being mounted to slide and turn on said rod with the cam-surfaces above said projection and in engagement therewith, whereby said shank will be rotated simultaneously with longitudinal movement, a foot-piece attached to said shank and a spring on said rod and engaging said shank to press the same against the projection, as and for the purpose set forth.

605,429. STAND FOR BICYCLES. WILLIAM H. HOWARD, Wokingham, England. Filed June 15, 1897. Serial No. 640,573. (No model.) Patented in England Oct. 6, 1896, No. 23,042.



Claim.—A bicycle-support, consisting of a rigid base-frame, two substantially perpendicular standards rigid therewith and rising therefrom, said standards being of different heights, a curved plate mounted on the shortest standard for supporting the crank-bracket of the bicycle, a slotted plate mounted on the longest standard, a thumb-screw adjustably connecting the slotted plate with said longest standard, two opening and closing jaws carried by the slotted plate for clamping the bicycle-frame above the crank-bracket, and a thumb-screw for operating one of said jaws, substantially as and for the purposes described.

605,430. AMMONIA AND WATER PISTOL. ALEXANDER F. HUMPHREY, Allegheny, Pa. Filed Aug. 3, 1897. Serial No. 646,905. (No model.)

Claim.—In a liquid-pistol, a shell or casing formed in two halves, each of said halves consisting of a portion of a handle or grip, a socket *b*, a bulged portion *d*, forming a receptacle, a barrel secured in said socket, a pocket *g*, formed in the inner end of said barrel, a flexible bulb, said flexible bulb being provided with a nipple registering with the opening in the barrel, a trigger journaled at the lower part of the bulged portion and between the two sections, said trigger being provided with a spoon-shaped extension being adapted to engage the rear of the flexible bulb to compress the same, whereby the liquid is ejected through the barrel, substantially as shown and described.

605,431. TRACK-CLEANER. WILLIS T. HURST, Mansfield, Ohio, assignor of two-thirds to Betty A. Baxter, Bennett C. Baxter, and Edwin D. Baxter, same place. Filed Aug. 23, 1897. Serial No. 649,217. (No model.)

Claim.—1. In a track-cleaner, the combination with a cleaning device, of a leaf-spring securely connected to said cleaning device and also connected to the car, an independent brace securely connected to the cleaning device and pivoted to the car, and a lever mechanism for actuating the cleaning device.

2. In a track-cleaner, the combination with independent cleaning devices, of a rock-shaft, leaf-springs secured to the rock-shaft and to the cleaning devices, and affording yielding connection for the latter, independent brace-rods secured to the cleaning devices and loosely hung on the rock-shaft, and means for turning the rock-shaft and locking the same, whereby the cleaning devices can be raised or lowered simultaneously, and are adapted for independent action when in operative position, substantially as described.

3. In a track-cleaner, the combination with a vertically-disposed cleaning-blade, of an adjustment member pivoted thereto and having an open serrated link, a bolt projecting from the blade and passing loosely through the link, a serrated washer on the bolt adapted to engage with the link and a connection between the adjustment member and the car, substantially as described.

4. In a track-cleaner, the combination with a cleaning-blade, of an adjustment member connected thereto and having a slot and a shoulder, a rod connected to the car and fitted in the slot, and provided with a bent end which abuts on the shoulder, and means for preventing the displacement of the rod, substantially as described.

5. In a track-cleaner, the combination with a cleaning-blade, of an adjustment member detachably connected thereto which has its face lying next the blade slotted inwardly and provided with a shoulder, a bar connected to the car and having a portion fitted in the slot and abutting on the blade and its end bent and lying against the shoulder, and a key passed into the member and fitted against the

bent end aforesaid to prevent displacement thereof, substantially as described.

6. In a track-cleaner, the combination with a cleaning-blade of a rock-shaft, a coupling-box consisting of sections detachably connected together and clamped around the rock-shaft, one of which has a slot and recess in its inner face, and a rod connected to the cleaning-blade and having its other end fitted in the slot and provided with a bent extremity received in the recess, substantially as described.

7. In a track-cleaner, the combination with a vertically-disposed cleaning blade or fender located above the track-rail, of a detachable or removable shoe connected to the bottom of said blade or fender in stationary relation thereto, substantially as described.

8. In a track-cleaner, the combination with a vertically-disposed cleaning-blade, of a casting connected thereto which is provided with a dovetail seat, and a shoe detachably fitted in said seat, substantially as described.

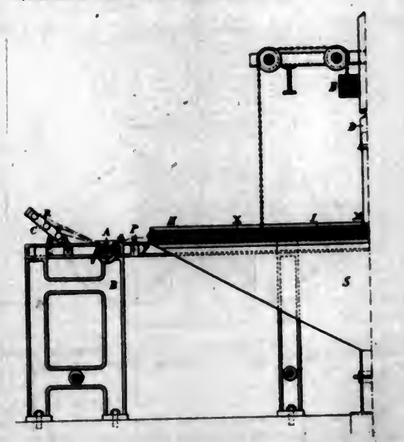
9. In a track-cleaner, the combination with a cleaning device, of a rock-shaft, a rod connecting the rock-shaft to the cleaning device, a pull-rod, means for automatically locking said pull-rod, and a connecting-rod pivoted to the pull-rod and having serrated jaws that tightly embrace the rock-shaft, and are fastened together, substantially as described.

605,482. BOILER-BRACE. ABRAM F. HUSTON, Contesville, Pa. Filed Jan. 21, 1898. Serial No. 667,480. (No model.)

Claim.—1. A boiler-brace made of sheet metal and having a flat head at one end and a head at the opposite end having flanges on each side thereof, said heads being connected together by a body-section, substantially as described.

2. A boiler-brace having a U-shaped body-section, a flat head at one end of the body-section and at an angle thereto, and a head at the opposite end having flanges at each side, substantially as described.

3. A boiler-brace having a body portion and two heads, one head being flat and at an angle to the body portion, the other head having flanges at each side, said flanges extending along a part of the body portion, said body portion being U-shaped at the opposite end, substantially as described.



605,483. BICYCLE-SUPPORT. JOSEPH H. ILER, Troy, N. Y. Filed Jan. 16, 1897. Serial No. 619,501. (No model.)

Claim.—1. In a bicycle-support, the combination with bearings connected to the opposite members of the rear fork, of horizontally-disposed shafts mounted in said bearings and located on opposite sides of said fork, front and rear legs carried at the opposite ends of said shafts, a reciprocable shifting bar or rod located in advance of the rear fork and passing vertically through the adjacent parts of the frame, said rod having an upper head and a notch therein below the head, a catch to engage the said notch in the shifting bar or rod, rocker-arms connected to the front portion of the shafts, and links pivotally connected to the rocker-arms and the lower end of the shifting bar on a single pivot, substantially as described.

2. In a bicycle-support, the combination with bearings connected to members of the rear fork, of horizontal shafts positioned on opposite sides of said fork and rotatably mounted in said bearings, legs connected to the opposite ends of said shafts, and means located in advance of the rear fork for operating said shafts and legs, substantially as described.

605,484. APPARATUS FOR APPLYING FINISHING SUBSTANCES TO COTTON FABRICS. CHARLES H. JACOB, Lyons, France. Filed Nov. 14, 1896. Serial No. 612,126. (No model.) Patented in France July 17, 1896, No. 258,123; in England Oct. 22, 1896, No. 23,499; in Italy Oct. 22, 1896, LXXXIV, 462; in Switzerland Nov. 10, 1896, No. 13,313, and in Belgium Dec. 5, 1896, No. 124,964.

Claim.—1. In an apparatus for sizing cotton thread, the combination with a frame carrying at one end suitably-supported bobbins of thread and sizing apparatus therefor, and at its other spool-winding mechanism, of a drier for the threads comprising a vessel having a heater therein, a cover removably secured to said drier a perforated plate arranged over the heater and beneath the cover, and thread-guides arranged between said cover and plate, substantially as described.

2. In an apparatus for sizing cotton thread, the combination with a frame carrying at one end suitably-supported bobbins of thread and sizing apparatus therefor, and at its other spool-winding mechanism, of a drier for the threads comprising a vessel having a heater therein, a cover removably secured to said drier, a perforated plate arranged over the heater and beneath the cover, thread-guides arranged between said cover and plate, and means for supporting said threads in their passage through the drier, substantially as described.

3. In an apparatus for sizing cotton thread, the combination with a frame carrying at one end suitably-supported bobbins of thread and sizing apparatus therefor, and at its other spool-winding mechanism, of a drier for the threads comprising a vessel having a heater therein, a cover removably secured to said drier, a perforated plate arranged over the heater and beneath the cover, thread-guides arranged between said cover and plate and means for supporting and guiding said threads in their passage through the drier comprising wheels or rollers suitably supported on the inner surface of said cover and plate, the wheels carried by the cover being above, and those carried by the plate below the plane of travel of the threads through the drier, substantially as described.

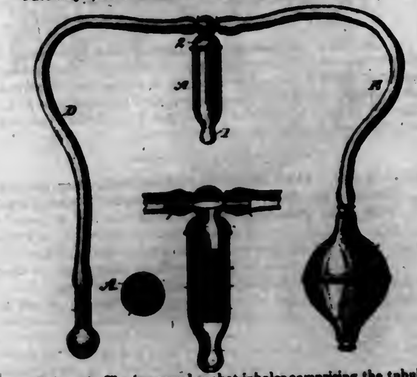
4. In an apparatus for sizing cotton thread, the combination with a frame carrying at one end suitably-supported bobbins of thread and sizing apparatus therefor, and at its other spool-winding mechanism, of a drier for the threads, means for conducting the threads therethrough, a cover removably secured to said drier, and counterbalance mechanism connected with the cover for raising the same, substantially as described.

5. In an apparatus for sizing cotton thread, the combination with a frame carrying at one end suitably-supported bobbins of thread and sizing apparatus therefor, and at its other spool-winding mechanism, of a drier for the threads, means for conducting the threads therethrough, a cover removably secured to said drier, a telescoping escape-flue carried by the cover and counterbalance mechanism connected with the cover for raising the same, substantially as described.

6. An apparatus for sizing cotton thread comprising, in combination, a hinged frame carrying a plurality of bobbins on which the thread is wound, a sizing device, drainers for removing the surplus sizing after the threads leave said vessel, a drier, comprising a vessel having a heater therein, a cover removably secured to said drier, a perforated plate arranged over the heater and beneath the cover, thread-guides arranged between said cover and plate, and spool-winding mechanism for winding the threads after they leave the drier, substantially as described.

605,485. SHEET-METAL VEHICLE-WHEEL TIRE. JAMES JAMIESON, Hamilton, Canada. Filed Mar. 17, 1897. Serial No. 627,988. (No model.)

Claim.—1. A series of tubular-shaped elastic sheet-metal sections formed with openings at the ends, each surrounded with a concavo-convex-shaped depression, for corresponding bolt-heads and nuts, grooves on the sections for strength and elasticity, and lugs or projections to hold a pad all constructed when spokes and hubs are attached thereto to form a wheel-tire for bicycles or other vehicles, substantially as specified.

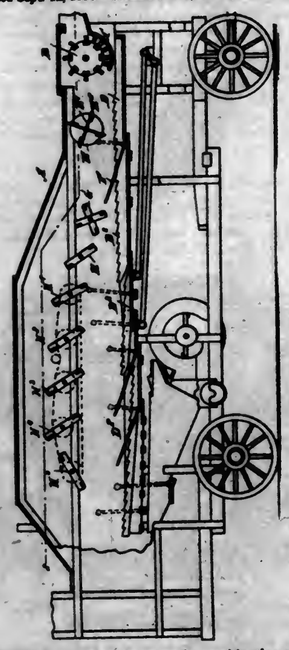


2. A series of elastic sheet-metal sections constructed with raised lugs *b*, for clasping a pad attached to each section, grooves *a*, *a*, for elasticity, lugs *b'*, *b'*, to clasp the sides when bent in tubular form, bolt-openings *c*, *c*, surrounded with concavo-convex recesses for corresponding bolt-heads and nuts, and openings *d*, *d*, for screws or rivets to fasten the sides together with a pad, and a lap *e*, substantially as and for the purpose specified.

3. A series of metallic tubular sections, A, each provided with a socket, *c*, for the end of a spoke, and each provided with a solid-rubber pad-section, B, secured directly and detachably thereto, these sections, A and B, collectively constituting a continuous, combined rim and tire, requiring no additional parts substantially as set forth.

4. In combination with the sheet-metal elastic sections, having bolt openings surrounded with concavo-convex recesses, bolts having the under side of the head formed convex to fit said recesses, a screw-thread on the outside for a concavo-faced threaded nut to screw thereon and a threaded hole on the inside to receive a spoke, substantially as and for the purposes specified.

5. A series of tubular sections, A, each having formed therewith one or more spoke-sockets, *c*, and two rows of outwardly-bent parts, *b*, in combination with rubber pads, B, fitted between these outwardly-bent parts and fastened to the said sections, the latter and the pads thereon forming a complete, continuous, combined tire and rim with rubber tread substantially as set forth.



605,486. INHALER. JOHN H. KELLOGG, Battle Creek, Mich. Filed July 2, 1897. Serial No. 643,910. (No model.)

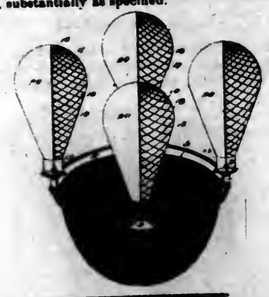
Claim.—1. The improved pocket-inhaler comprising the tubular mouthpiece having a longitudinal passage, and an absorbent and holder for the vaporizable medicament, which holder is contained in said mouthpiece, the nose-piece, and compressible air-bulb, and separate flexible tubes connecting the latter two directly with each other and also with one of the open ends of the mouthpiece, as shown and described, whereby air may be forced from the bulb directly through the mouthpiece, or directly to the nose-piece, or from the patient's mouth through the mouthpiece to the nose-piece, as required.

2. The improved inhaler, composed of the tubular mouthpiece, and the absorbent and holder therein, said mouthpiece having two nipples which communicate directly with each other, the nose-piece and its flexible tube connected with one of said nipples, and the air-bulb and its flexible tube connected with the opposite nipple, as shown and described, whereby air-pressure in the nasal cavity produced by expulsion of air directly through the mouthpiece and nose-piece may be augmented at pleasure, by compression of the air-bulb, as specified.

605,487. GRAIN-SEPARATOR. JACOB F. KOCH, New Athens, Ill., assignor to himself, and the Harrison Machine Works, Belleville, Ill. Filed Sept. 13, 1898. Serial No. 605,580. (No model.)

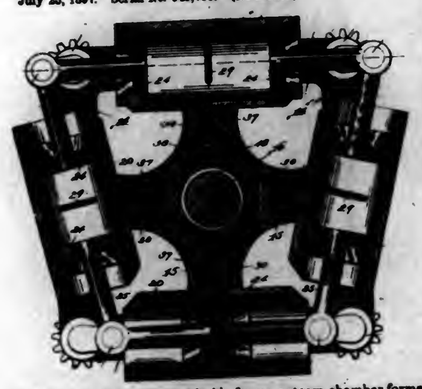
Claim.—1. In a grain-separator, the combination of a threshing-cylinder and concave, a vibrating separating-pan located below the cylinder and concave and receiving the straw and grain from the cylinder and concave, a straw-beater located above the separating-pan in rear of and adjacent to the cylinder, the straw-beater serving to throw the grain and straw downward upon the separating-pan and to spread the straw, a vibrating lifting-rack located in rear of the straw-beater and serving to raise the straw and other coarse material from the separating-pan, and an elevated straw-carrier over the separating-pan and receiving the straw from the said lifting-rack.

2. In a grain-separator, the combination of a threshing-cylinder and concave, a vibrating separating-pan located below the cylinder and concave, the separating-pan receiving the straw and grain from the cylinder and concave, a vibrating lifting-rack located in rear of the point on the separating-pan, which point first receives the straw and grain, and serving to raise the straw and other coarse material from the separating-pan, and an elevated straw-carrier located over the separating-pan and receiving the straw from said lifting-rack.



3. In a grain-separator, the combination with the threshing-cylinder and its concave, of a separating-pan having one end extending under the concave, a revolvable beater in rear and adjacent to the cylinder for throwing the straw and grain down upon the separating-pan, a series of revolvable straw-lifters in rear of the beater and above the separating-pan, the lifters being of gradually-increasing diameters, and the front and rear lifters having their axes below the intermediate ones, and a vibrating rack arranged between the beater and the first lifter and serving to raise the straw and other coarse material from the pan and guide it onto the said lifters, substantially as herein shown and described.

605,488. AIR-SHIP. ADOLPH KOEHLER, New York, N. Y. Filed Sept. 17, 1897. Serial No. 652,043. (No model.)



Claim.—1. The combination with a basket, of a balloon-rail surrounding the same, a plurality of balloon-brackets adjustably mounted upon the rail, and balloons connected with said brackets, substantially as specified.

2. The combination with a basket, of a balloon-rail surrounding

the same, balloon-brackets adjustably mounted upon the rail, rotatably-adjustable heads carried by said brackets, and balloons secured to the heads, substantially as specified.

605,489. MOTOR. JOHN F. W. KOETTER, St. Louis, Mo. Filed July 23, 1897. Serial No. 645,735. (No model.)

Claim.—1. In a motor, a suitable frame, a steam-chamber formed in the center of said frame, bearings formed in the sides of said frame, suitable cylinders, trunnions formed integral with the centers of said cylinders, which trunnions operate in the previously-mentioned bearings, in which trunnions are formed ports that are arranged to communicate with ports formed in the frame, certain of which ports communicate with the steam-chamber in the frame, shafts journaled in the corners of the frame, on which shafts are formed cranks, pistons operating in each end of each of the cylinders, piston-rods connecting said pistons with the cranks, pinions mounted upon the shafts on the opposite end from the cranks, a rotatable shaft passing through the motor-frame, and a gear-wheel mounted upon said shaft, which gear-wheel meshes with the pinions, substantially as specified.

2. In a motor, a suitable frame, in the center of which is formed a suitable steam-chamber and in which frame are formed suitable steam-ports, certain of which ports communicate with said chamber, a plate located upon the front of the frame to form a chamber with which the remaining ports communicate, bearings formed in the sides of the motor-frame, suitable steam-cylinders, trunnions formed integral with the centers of said cylinders, which trunnions operate in the bearings of the frame, in which trunnions are formed ports that communicate with the hereinbefore-mentioned ports, pistons operating in each end of each cylinder, crank-shafts rotatably mounted in the corners of the motor-frame, piston-rods connecting the pistons with said crank-shafts, pinions located upon said crank-shafts, a rotatable shaft passing through the center of the motor-frame, a gear-wheel fixed upon said shaft, a bearing-plate carried by the motor-frame, a bearing-plate carried by the gear-wheel, and ball-bearings interposed between said bearing-plates, substantially as specified.

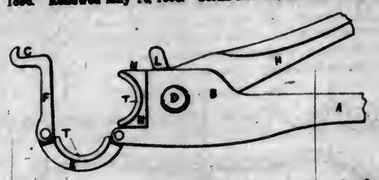
3. In a motor, a plurality of cylinders arranged radially relative to a given point, pistons operating in each end of each of said cylinders, piston-rods for said pistons, the end of each piston-rod being connected to the next adjacent piston-rod, and means whereby fluid is introduced between said pistons, substantially as specified.

4. In a motor, a plurality of cylinders arranged radially relative to a given point, pistons operating in each end of each of said cylinders, piston-rods for said pistons, each piston-rod being connected to the next adjacent piston-rod, which cylinders, pistons and piston-rods form connections whereby their force is united, and means of injecting fluid between said pistons, substantially as specified.

5. In a motor, a shaft rotatably mounted, a frame carried by said shaft, a plurality of cylinders carried by said frame and arranged radially relative to the shaft, pistons operating in each end of each of said cylinders, piston-rods for said pistons, each one of said piston-rods being connected to the next adjacent piston-rod to unite the force of the pistons, means whereby fluid is injected into the cylinders between the pistons, and means for transmitting the united force of the pistons to the rotatably-mounted shaft, substantially as specified.

605,440. PENCIL-SPLICER. FRANK W. WARREN, San Francisco, Cal. Filed July 1, 1897. Serial No. 643,068. (No model.)

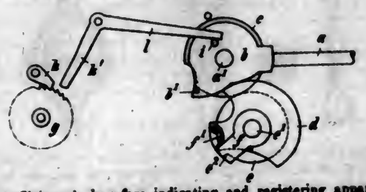
Claim.—1. A pencil-holder consisting of a short tube internally threaded and with the threads cut transversely to present a sharp angle which forms a cutting-die.



2. A pencil-splicer consisting of a short tube having a threaded interior and a many-sided exterior, said internal threads being grooved transversely to present a sharp angle forming a cutting-die.

3. A pencil-splicer consisting of a short tube with internal screw-threads adapted to engage pencils introduced from opposite ends and having transverse cuts made across the threads to form a die to cut the threads upon said pencils.

4. A pencil-splicer consisting of a short tube internally threaded and having a diverging or bell-shaped end and transverse cuts made across the threads to present a sharp angle which forms a cutting-die.

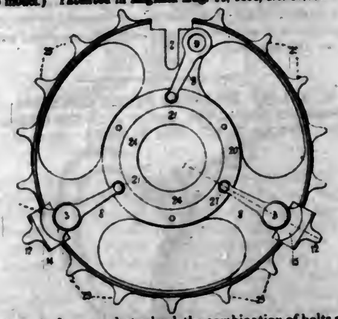


5. A pencil-splicer consisting of a short tube having internal screw-threads and having its opposite ends bell-shaped or diverging whereby pencils may be introduced from both ends, and having interior transverse cuts or grooves forming cutting-dies for the threads.

605,441. PIPE-WRENCH. ATWATER B. BROCKETT, Everett, Mass., assignor to William G. Hixon, Braintree, Mass. Filed May 14, 1896. Renewed May 14, 1898. Serial No. 680,761. (No model.)

Claim.—In a pipe-wrench, the handle A having the flanges B and provided with the pivoted clamp-jaw E having the pivoted coupling-link F, and the pivoted lever-handle H, having the eccentric K and projecting stud L, the sliding clamp-jaw N having flanges P, fulcrum-bolt D, and the removable face-pieces T, all constructed combined and arranged, substantially as set forth

605,442. FARE INDICATING AND REGISTERING APPARATUS FOR CABS, &c. FRIEDRICH W. G. REDER, Berlin, Germany. Filed Jan. 26, 1898. Serial No. 667,945. (No model.)



Claim.—1. In a fare indicating and registering apparatus for cabs, carriages and the like, the combination of the signal device *a*, the shaft *a'*, the disks *b* and *c*, with the shaft *c'* and disks *e* and *d*, substantially as and for the purpose specified.

2. In a fare indicating and registering apparatus for cabs, carriages and the like, the combination of the signal device *a*, the shaft *c'*, the disk *b* and pin *b'*, with the shaft *c'*, disk *d*, cam *f* and spring *f'*, substantially as and for the purpose specified.

3. In a fare indicating and registering apparatus for cabs, carriages and the like, the combination of the signal device *a*, shaft *a'*, disk *b* and catch *i*, with the lever *k l*, pawl *h* and disk *g*, substantially as and for the purpose specified.

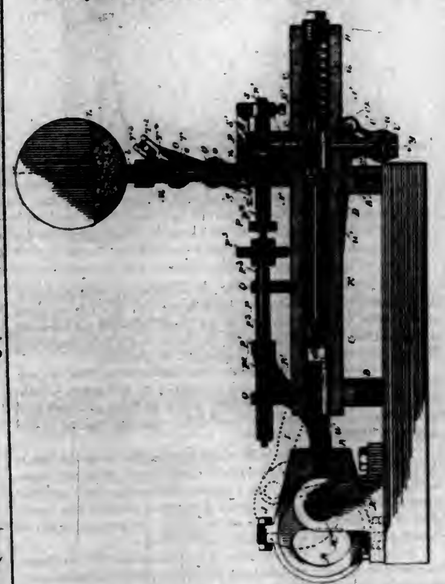
605,443. SPROCKET-WHEEL. LOUIS COOPER and EDWARD W. COOPER, Coventry, England. Filed Mar. 2, 1897. Serial No. 625,776. (No model.) Patented in England Aug. 11, 1896, No. 17,706.

Claim.—1. In a sprocket-wheel, the combination of bolts adapted to move radially, nuts to lock the bolts, movable driving-teeth carried by the said bolts, links pivotally connected at their outer ends with the said bolts, a boss formed concentrically with the said wheel, a ring rotatably mounted on the said boss and pivotally connected with the inner ends of the said links, and guide-teeth situated between the driving teeth, substantially as described and for the purpose set forth.

2. In a sprocket-wheel having driving-teeth adjustable radially to the pitch of the chain and guide-teeth situated between such driving-teeth, the combination with such driving-teeth of bolts to carry the said driving-teeth, nuts to screw on the bolts, links pivotally connected by their outer ends to the said bolts, a boss concentric with the wheel, and a ring rotatably mounted on the said boss and pivotally connected to the inner ends of the said links substantially as described and for the purpose set forth.

605,444. RATCHET MONKEY-WRENCH. CLAYTON E. FREDERICKSON, Denver, Colo. Filed Jan. 7, 1898. Serial No. 665,902. (No model.)

Claim.—1. The combination of the rotatable head-stock having a transverse channel, with the oppositely-moving sliding jaws sustained in and guided by said channel, the bolt movable axially of said head-stock above the jaws, and links connecting said bolt to said jaws, for the purpose and substantially as described.



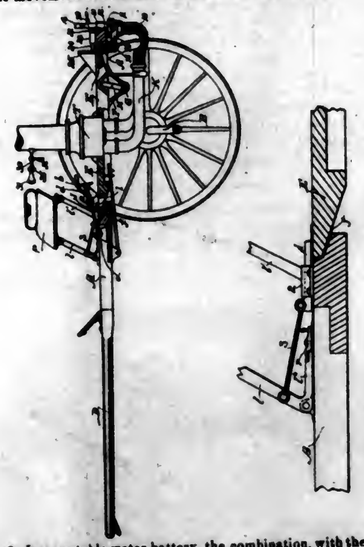
2. The combination of the handle, the rotatable head-stock thereon having a transverse channel, with the oppositely-moving jaws guided in said channel, the bolt movable axially of said head-stock above the jaws, and links connecting said bolt to said jaws; with means for rotating said head-stock by vibrating the handle, all substantially as and for the purpose described.

3. The combination of the head having a transverse channel provided with opposite ribs inclining upwardly and inwardly from circumference to center; the sliding jaws having heads moving in said channel provided with grooves engaging the ribs therein, a bolt above the jaws movable substantially at right angles thereto, and the links pivotally connected to the lower end of said bolt at their upper ends, and respectively connected at their lower ends to the opposite jaws, and means for adjusting said bolt, substantially as described.

4. The combination of the handle, the rotatable head-stock journaled in the end thereof having a transverse groove provided with ribs on its sides, inclined upwardly from periphery to center, sliding jaws having heads provided with lateral grooves engaging the ribs in said channel, a bolt movable axially of the head-stock and connected to the respective jaws by means of pivoted links; a nut for actuating said bolt, and means for securing said nut to the head-stock while allowing it to rotate thereon; with means for rotating said head-stock when the handle is vibrated, substantially as described.

5. The combination of the handle, the rotatable head-stock journaled in the end thereof, and a retaining-plate for securing said head-stock to the handle; said head-stock having a circumferential ratchet, and a transverse groove in its under face provided with ribs on its sides inclined upwardly from periphery to center; sliding jaws having heads moving in said channel and provided with lateral grooves engaging the ribs therein; a bolt movable axially of the head-stock, links connecting said bolts to the respective jaws, a nut on said bolt and means for rotatably securing said nut to the head-stock; with opposite dogs adapted to engage the ratchet on the head-stock, the spring interposed between the ends of the dogs; and the connected catches adapted to hold either dog out of engagement with the ratchet, all for the purpose and substantially as described.

605,445. POWDER-MOTOR. THOMAS M. FREEBLS, Latrobe, Pa., assignor of one-fourth to Thomas B. Atterbury, Jr., Pittsburg, Pa. Filed July 14, 1897. Serial No. 644,512. (No model.)



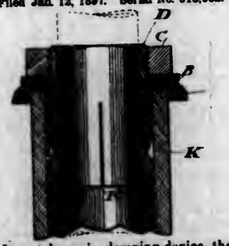
Claim.—1. In a powder-engine, the combination with a cylinder, an igniting device, and a piston or pistons to transmit the power derived from the explosion of the charges of powder, of powder feed and exhaust mechanisms, and powder feed and exhaust openings in said cylinder, said powder-feed opening being formed vertically over said exhaust-opening, whereby accumulation of successive charges in the cylinder is prevented, substantially as described.

2. In a powder-engine, the combination with a cylinder, powder feed and exhaust mechanisms, powder feed and exhaust openings in said cylinder formed in vertical line, and an igniting device of oppositely-acting pistons within said cylinder stationed one on either side of said igniting mechanism, one of said pistons being detached or not connected with power, a piston-rod attached to one of said pistons, a crank-pin projecting therefrom, guides therefor formed by an opening in the walls of said cylinder, connection between said crank pin and a power-shaft, a spring for normally holding said detached piston pressed forward and for returning it to its forward position after the successive explosions, and means for introducing water into said cylinder after each explosion, substantially as described.

3. In a powder-engine, the combination with a cylinder having powder feed and exhaust openings therein, said openings being placed in line with each other, powder feed and discharge valves, a power-shaft, and means for rotating said powder feed and exhaust valves from the rotation of said shaft, substantially as described.

605,446. PORTABLE WATER-BATTERY. HENRY H. GORTER, San Francisco, Cal., assignor to Mary E. Gorter, same place. Filed Dec. 10, 1897. Serial No. 661,468. (No model.)

Claim.—1. In a portable water-battery, the combination, with the frame, the siamesing-chamber, and the platform therefor movably mounted on the frame, of a movable seat on the frame, and a bolt for locking the platform to the frame, said bolt being operated by the movement of said seat, substantially as described.



2. In a portable water-battery, the combination, with the frame, the siamesing-chamber, and the platform therefor movably mounted on the frame, of a driver's seat on the frame, mounted on vibrating legs, a bolt locking the platform to the frame, and a link connecting the bolt with one of the legs, substantially as described.

3. In a portable water-battery, the combination, with the supply-pipes, of flexible hose-sections connected to said pipes, a rock-shaft, arms extending from said shaft, said arms being provided with sockets, and studs on the free ends of the sections, resting in said sockets, substantially as described.

4. In a portable water-battery, the combination, with the frame, the platform movable therein and the supply-pipes, of flexible hose-sections connected to said pipes, a support for the free ends of all the pipes, a latch holding said support, and means whereby the movement of the platform relatively to the frame operates said latch to release said free ends, substantially as described.

5. In a portable water-battery, the combination, with the frame, the platform movable therein, and the supply-pipes, of flexible hose-sections connected to said pipes, a support for the free ends of all the pipes, and a latch holding said support, and adapted to be operated independently of the movement of the platform to release the free ends of the hose-sections, substantially as described.

605,447. TELESCOPIC CLAMP. GEORGE W. KORTRIGHT, Sioux City, Iowa. Filed Jan. 12, 1897. Serial No. 618,962. (No model.)

Claim.—1. In a telescopic clamping device, the combination of an outer tubular member, a ring fastened inside its end, an inner tubular slotted clamping member having a beveled shoulder thereon engaging said ring, and a nut threaded on the projecting end of said inner member and bearing against the outer member, as set forth.

2. In a telescopic clamp, the combination with the inner and outer tubings, the slitted shell D threaded at its upper end and fitted into the outer tubing, the recessed cap G mounted on the end of the said outer tubing, the clamping-shell B having a flanged upper end, the cylindrical portion of shell B slitted and fitted about the contracted portion of shell D, and the tightening-nut threaded on the upper end of the inner shell and bearing against the flange of the outer shell, as shown and described.

605,448. INSULATING HANDLE CONNECTION. WILLIAM MCAUSLAND, Taunton, Mass., assignor to the Reed & Barton Corporation. Filed Apr. 30, 1897. Serial No. 634,631. (No model.)

Claim.—1. In an insulated handle the combination of the members secured to the vessel, the handle proper, the insulated section and means for securing the parts together, said insulated section having a cup-shaped chamber and carrying the insulating material, the chambered section concealing the insulating material and arranged out of contact with one of the members of the handle, substantially as described.

2. In an insulated handle, the combination of the members secured to the vessel, the handle proper, the insulated section and means for securing the parts together, the said insulating-section having a cup-shaped chamber and carrying the insulating material, the chambered section concealing the insulating material, and arranged out of contact with one of the members of the handle, and an insulated washer F, for insulating the securing means, substantially as described.

605,449. PRESSER-FOOT AND THROAT-PLATE FOR SEWING-MACHINES. CHESTER MCNEIL, Rogers Park, Ill., assignor to The Union Special Sewing Machine Company, Chicago, Ill. Filed Aug. 9, 1894. Serial No. 519,844. (No model.)

Claim.—1. In a sewing-machine, the combination with mechanism for passing a plurality of rows of loops through the fabric of a presser-foot and work-plate, a guiding-fin on one of said elements arranged in the line of the seam, the other element being provided with a slot with which said fin is in alinement, and means for varying the width of said slot; substantially as described.

2. In a sewing-machine, the combination with mechanism for making a plurality of rows of stitching, of a presser-foot and work-plate, a guiding-fin on one of said elements arranged in a line between the rows of stitching, the other element being provided with a slot with which said fin is in alinement, means for varying the width of said slot, and means also for adjusting the guiding-fin; substantially as described.

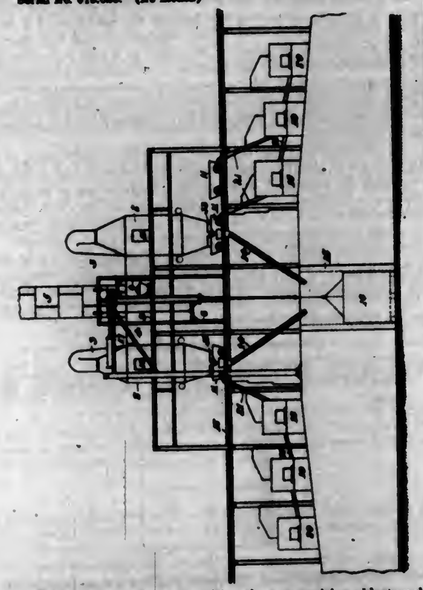
3. In a sewing-machine making two parallel rows of stitching the combination with a presser-foot having a longitudinal slot of a throat-plate provided with a longitudinal guiding-fin registering with said slot and arranged in a line between the rows of stitching and means for varying the width of said slot; substantially as described.

4. The combination with a presser-foot having a longitudinal slot of a throat-plate provided with a longitudinal guiding-fin adapted to register with said slot, means for adjusting the walls of, and thus varying the width of said slot, and for adjusting the guiding-fin; substantially as described.

5. The herein described presser-foot having the bifurcated forward end, the rigid side pieces and the removable spring-plate secured to the presser-foot and conforming at the front to the shape of the foot, and adjusting-screws for regulating the distance apart of the ends of said spring; substantially as described.

6. The combination with a presser-foot and throat-plate, one of said elements being provided with a longitudinal slot and the other element having a fin adapted to register with said slot, with means for adjusting said parts; substantially as described.

605,450. NUT. REE R. PARRISH, Independence, Oreg. Filed July 21, 1897. Serial No. 645,205. (No model.)



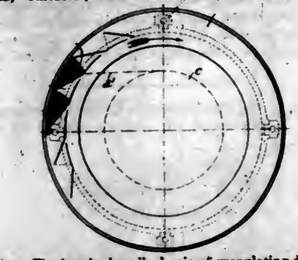
Claim.—1. As a new article of manufacture, a nut, said nut having two or more contiguous front corners, front and rear edges, a wrench-knob located between two contiguous corners, not extending to either of said corners, wrench-space between said knob and said rear edge, substantially as and for the purposes set forth.

2. The combination in a nut having a circular rear edge, a front edge provided with two or more contiguous front corners, of a wrench-knob located adjacent to two contiguous front corners, not extending to either of said corners, substantially as and for the purposes set forth.

3. The combination in a nut having an enlarged rear edge, a front edge provided with two or more contiguous front corners, of a wrench-knob located adjacent to two contiguous front corners, not extending to either of said corners, substantially as and for the purposes set forth.

605,451. CONTINUOUS SMELTING PLANT. WILLIAM B. REESE and EDWARD R. ARMSTRONG, Natrona, Pa., assignors to the Pennsylvania Salt Manufacturing Company, Philadelphia, Pa. Filed Jan. 5, 1897. Serial No. 618,026. (No model.)

Claim.—1. A continuous smelting plant, comprising a blast smelting-furnace, a movable settler therefor, a series of reducing-furnaces, and means for feeding the metal from the settler into any one of said reducing-furnaces.



2. A continuous smelting plant, comprising an elevated smelting-furnace, a movable settler therefor, a series of reducing-furnaces at successively lower levels, and means for feeding metal from the settler into any one of the reducing-furnaces.

3. The combination with a blast smelting-furnace, of a wheeled settler therefor resting upon a track, a series of reducing-furnaces at successively lower levels than the smelting-furnace and located along the track, and means for feeding the metal from the settler into any one of said reducing-furnaces.

4. A continuous smelting plant, comprising a smelting-furnace, a movable settler therefor, a series of reducing-furnaces, means for feeding the metal from the settler into any one of said reducing-furnaces, a slag-pit arranged to contain water, and means for feeding slag from the settler to said pit.

5. A continuous smelting plant comprising two elevated smelting-furnaces located side by side and provided with wheeled settlers resting on a common track, a series of reducing-furnaces for each smelting-furnace and located at successively lower levels than the smelting-furnace, and feeders arranged to transfer the metal from the settlers to the reducing-furnaces, and from one reducing-furnace to the next lower one.

605,452. GRANULATING-DISK. HENRI ROSE and GEORGES ROSE, Poissy, France. Filed June 11, 1896. Serial No. 595,200. (No model.) Patented in France Oct. 24, 1889, No. 201,532.

Claim.—The herein-described pair of granulating-disks for corn and other mills, the same consisting of the stationary granulating-disk having its acting face composed of an annular crown provided with rectilinear furrows radiating from the central portion of the disk to the circumference, and the rotary granulating-disk having its acting face constituted by an annular crown provided with a series of furrows which are directed from the circumference tangentially to an imaginary circle concentric with the said disk and having depressed triangular inlets interrupting said tangential furrows at regular intervals, the said stationary disk and rotary disk being arranged to operate with their acting faces opposite to and parallel with each other, and each disk having the exterior acting edges of all its furrows in the same plane, substantially as specified

605,458. COMBINATION-TOOL FOR BICYCLES. EMANUEL W. SWEHARD, Chicago, Ill. Filed Mar. 20, 1896. Renewed Jan. 31, 1898. Serial No. 668,672. (No model.)

Claim.—1. In a pump-wrench, the hollow pump-body, a wrench-stem arranged to traverse the pump-body, a plunger secured to the end of the stem within the body, a fixed jaw and a movable jaw at

the other end of the stem, and a finger-piece for operating the movable jaw, the opening in the body through which the wrench-stem passes being large enough to permit the jaws and finger-piece to pass therethrough, whereby the said jaws and finger-piece can be housed within the pump-body to some degree, substantially as described.

2. In a device of the class described, the combination with a flat pump-cylinder approximately rectangular in transverse section, of a piston-rod sliding and guided in said pump-cylinder and provided at one end with a piston and at the opposite end with a transverse member adapted to serve as the stationary jaw of a wrench, a shank sliding and adjustable in said piston-rod and provided with a terminal jaw adapted to cooperate with said transverse terminal member on the piston-rod, and a nut lying within the piston-rod and engaging the shank sliding therein, the pump-cylinder being adapted to receive within it the entire piston-rod with the exception of said transverse terminal jaw, whereby when the parts are closed together the adjusting-nut is within the pump-cylinder and covered and protected thereby.

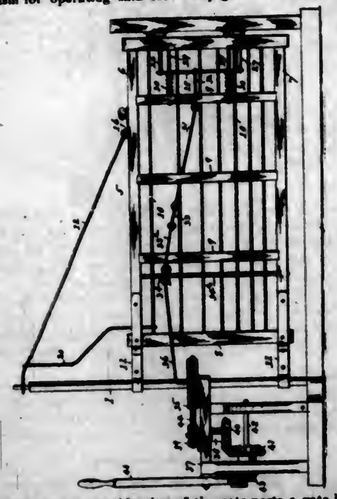
605,454. GRIPPING DEVICE. ERNEST A. THOMPSON, Englewood, N. J. Filed Apr. 29, 1897. Serial No. 634,467. (No model.)

Claim.—1. In an organized device for holding objects on work-benches, the combination of a vertically-adjustable serrated bench-stop, an independent vertically-adjustable gripping device, pivoted so as to automatically cooperate therewith horizontally, and means for locking the same in position, substantially as described.

2. In an organized device for holding objects, the combination of a vertically-adjustable serrated bench-stop, an independent vertically-adjustable gripping device adapted to move horizontally and automatically cooperate with the bench-stop, and a stop adapted to engage with the body of the device, controlling the lateral movement of the gripping device.

3. In an organized device for holding objects on a work-bench, the combination of a tray countersunk to receive the component parts, a vertically-adjustable rigid serrated bench-stop, a vertically-adjustable gripping device, pivoted so as to move horizontally and cooperate with the serrated stop, and a locking device adapted to engage with serrations in the body of the tray to regulate the lateral movement of the gripping device.

4. In an organized device for holding objects on work-benches, the combination of a tray countersunk to receive the component parts flush with the surface of the bench, a bench stop fitted therein, and adapted to be adjusted perpendicularly thereto, an independent perpendicularly-adjustable clamp, adapted to cooperate with the bench-stop to secure an object between them by means of the insertion thereof, and means for adjusting the clamp laterally in said tray.



5. In combination, for the purposes described, a countersunk tray adapted to receive the component parts flush with the upper surface, a rigid but vertically-adjustable serrated bench-stop, having its interior face concaved in the direction of its length, a vertically-adjustable clamp having its interior face similarly concaved and adapted to cooperate with the bench-stop to grip an object between them by its insertion, a sliding block bearing the clamp, and a lever on said block adapted to engage with the tray, substantially as described.

6. In an organized device for holding objects on work-benches, the combination of a vertically-adjustable serrated bench-stop: an independent vertically-adjustable gripping device pivoted so as to rotate horizontally and automatically cooperating therewith, and means for locking the same in position, substantially as described.

7. The combination of a vertically-adjustable bench-stop, an independent vertically-adjustable clamp, adapted to cooperate with the bench-stop to secure an object between them by means of the insertion thereof, and means for adjusting the clamp laterally.

605,455. GATE. HENRY B. WESTON, Kenton, Ohio, assignor of one-half to Bessie W. Thomson, same place. Filed Aug. 25, 1897. Serial No. 649,510. (No model.)

Claim.—1. In gates, the combination of the gate-posts, a gate hinged or pivoted to one post, latch mechanism on the gate to engage the other post, a gear-wheel loosely mounted on the hinging-post to oscillate, a lever centrally pivoted on the gate, rods pivoted to the said gear and connected with opposite ends of said lever, a connecting-plate, link-rods connecting the said lever and connecting-plate, a connection between the connecting-plate and latch mechanism, and mechanism for operating said oscillatory gear, substantially as described.

2. In gates, the combination of the gate-posts, a gate hinged or pivoted to one post and provided with latch mechanism to engage the other post, an oscillatory gear-wheel on the hinging-post, a pivoted lever on the gate, connecting-rods between the gear-wheel and said lever, a retractor-rod connecting said pivoted lever and latch mechanism, a vertical shaft having at its upper end a gear in connection with said oscillatory gear and carrying at its lower end a bevel-gear, a horizontal drive-shaft having a bevel-gear meshing with said bevel-gear on the vertical shaft, pivoted operating-levers, and a connection between said levers and drive-shaft for operating the latter, substantially as described.

3. In swinging gates, the combination with the gate-posts, of a gate hinged or pivoted to one post and provided with a latch device to engage the other post, an oscillatory sprocket-wheel on the hinging-post, a connection between said gear-wheel and the latch device to retract the latter and swing the gate, a vertical shaft carrying at its upper end a sprocket-pinion and at its lower end a bevel-gear, a horizontal drive-shaft carrying a bevel-gear meshing with said bevel-gear on the vertical shaft and a drum or pulley, a chain connecting said sprocket-pinion and oscillatory sprocket-wheel, pivoted operating-levers, and connections between said levers and the said drum or pulley, substantially as described.

605,456. KEY-OPENING CAN. EDWARD BARRATH, Chicago, Ill. Filed Sept. 10, 1894. Renewed June 26, 1897. Serial No. 642,523. (No model.)

Claim.—1. The combination with the body portion of a can provided with an oblique flange, of a cover provided with an oblique rim extending upward and outward, a circumferential line of reduced strength extending about said rim and a free lip adapted to be grasped to tear the cover along said line of reduced strength, substantially as described.

2. The combination with the body portion of a can provided with an oblique flange, of a cover provided with an oblique rim extending upward and outward, an offset being provided on said cover between the rim and the face thereof, said cover being provided with a line of reduced strength extending circumferentially about said rim, and a free lip adapted to be grasped to tear the cover along said lines of reduced strength, substantially as described.

605,457. KEY-OPENING CAN. EDWARD BARRATH, Chicago, Ill. Filed Sept. 10, 1894. Renewed June 26, 1897. Serial No. 642,580. (No model.)

Claim.—1. The combination with the body portion of a can, of a cover provided with an upwardly-extending rim, the edge of said rim being turned down and secured to the can-body, said rim carrying two lines of reduced strength extending circumferentially about the same, and a free lip adapted to be grasped to tear said cover along said lines of reduced strength to remove the material of the cover lying between the same, substantially as described.

2. The combination with the body portion of a can, of a cover provided with an oblique rim extending upward and outward, the edge of said rim being turned down and secured to said can-body, said rim being provided with two circumferential lines of reduced strength extending about the same, and a free lip adapted to be grasped to tear said cover along said lines of reduced strength to remove the material of the cover lying between the same, substantially as described.

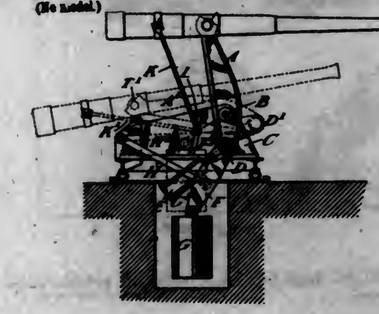
605,458. PROCESS OF MAKING SULFIDS. HENRY S. BLACKMORE, Mount Vernon, N. Y. Filed July 22, 1896. Renewed Apr. 21, 1898. Serial No. 678,438. (No specimens.)

Claim.—1. The process for producing aluminium and other sulfids which consists in exposing a molten aluminate to the action of carbon-bisulfid vapor or gas substantially as described.

2. The process for producing aluminium and other sulfids which consists in making or fusing a metallic aluminate and passing through the same a compound of carbon and sulfur in vaporized or gaseous state substantially as described.

3. The process for producing aluminium and other sulfids which consists in exposing a molten aluminate to the combined action of sulfur and carbon in a volatilized or gaseous state, substantially as described.

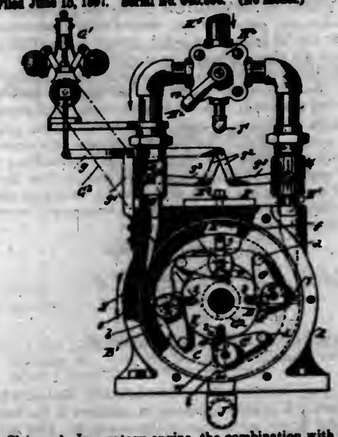
4. The process for producing aluminium and alkali sulfids which consists in exposing a molten mixture of sodium and potassium aluminate to the action of carbon bisulfid substantially as described.



5. The process for producing aluminium and other sulfids which consists in transforming compounds of aluminium oxid with more electropositive element, the said aluminium oxid existing as electronegative or acid in the compound, by passing through said compound in a molten state a current of carbon-bisulfid vapor or gas substantially as described.

6. The process for producing aluminium and other sulfids which consists in passing vapor of carbon bisulfid through a fluid mass of an oxy compound of aluminium with an element or elements of more electropositive nature, such as sodium aluminate, substantially as described.

7. The process for producing aluminium and other sulfids which consists in fusing a compound produced by combining aluminium oxid with an oxid of an element or elements of more electropositive nature and exposing the same in a fused condition to the action of carbon-bisulfid vapor or gas substantially as described.



8. The process for producing aluminium and other sulfids which consists in exposing a compound of aluminium oxid with an oxid or oxids of metal or metals of more electropositive nature, to the action of carbon bisulfid substantially as described.

605,459. MOUNTING FOR DISAPPEARING GUNS. ARTHUR T. DAWSON, Sheffield, England. Filed Feb. 19, 1896. Serial No. 670,947. (No model.)

Claim.—In the mounting of a disappearing gun the combination of a pair of pivoted levers having bearings at their upper ends for the trunnions, and jointed at their lower ends to the plunger of a recoil-cylinder and also to another pair of pivoted levers which carry a weight and are pivoted on a pair of radius-rods, said radius-rods being connected to the gun-carriage, substantially as and for the purpose set forth.

605,460. ROTARY ENGINE. MELVIN R. GILBERT, San Francisco, Cal., assignor of one-half to Frank P. Winchenbaugh, Fresno, Cal. Filed June 15, 1897. Serial No. 640,896. (No model.)

Claim.—1. In a rotary engine, the combination with the casing having in its opposite end walls cam-grooves 11, 11, of the radially-slotted disk, the rings or flanges C having radial grooves in their inner faces only, the radially-slidable wings movably secured in the said slots and grooves, the cam-arms pivotally fulcrumed in the rings or flanges, rolls working in the cam-grooves mounted on the cam-arms, and a pivotal sliding connection between the cam-arms and wings, substantially as described.

2. In a rotary engine, the combination with the casing, of the drive-shaft passing therethrough, the disk secured to the drive-shaft and located within the casing so as to leave an annular passage-way between the periphery and the inner face of the casing, rings or flanges secured within the casing at each side of the disk, radial slots cut in the disk and radial grooves or channels cut in the inner face of the rings or flanges, a series of wings or blades mounted to slide vertically in the radial slots and grooves or channels, the oscillatory cam-arms fulcrumed to the outer face of the rings or flanges, pivotal sliding connection between the oscillatory cam-arms and the movable wings or blades, devices for raising and lowering the fulcrumed oscillating cam-arms, and of the inlet and outlet ports in the casing.

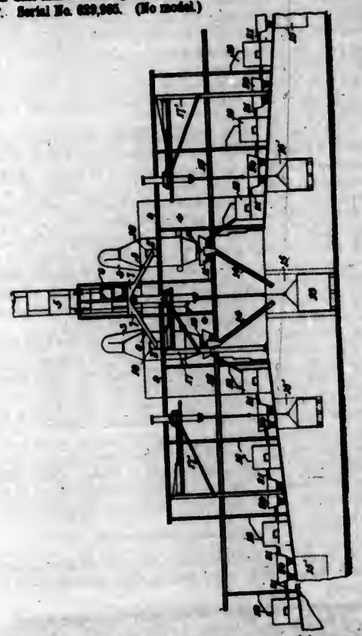
3. In a rotary engine, the combination with the casing thereof, of the face-plates therefor, the eccentric groove formed in the inner face of the face-plates, the disk mounted to rotate within the casing, the rings or flanges located at each side of the disk, radial slots cut in the disk and radial channels in the inner face of the rings or flanges, a series of vertically-movable wings or blades working in said radial slots and channels, oscillatory cam-arms fulcrumed to the outer face of the rings or flanges, pivotal sliding connection between the oscillatory fulcrumed cam-arms and the wings or blades, bearing-rolls carried by the fulcrumed oscillatory cam-arms which travel within the eccentric groove of the face-plates, and of the inlet and outlet ports in the casing.

605,461. FRUIT-PICKER. OSCAR W. HUDGINS and JAMES A. JONES, Harrison, Ark. Filed Aug. 12, 1896. Serial No. 602,467. (No model.)

Claim.—1. In a fruit-picker, the combination with the sectional adjustable handle, of the side pieces at the upper end thereof, the semicircular pieces secured to the side pieces, the horizontal rods con-

necting the side pieces and having the handle secured thereto and the curved grabbers mounted on the semicircular pieces, substantially as specified.

2. In a fruit-picker, the combination with the sectional adjustable handle, of the side pieces at the upper end thereof, the cross rods connecting said side pieces and to which the handle is attached, the semicircular pieces secured to the side pieces, and the curved grabbers mounted on the semicircular pieces, and the sack secured at its upper end to the side pieces, substantially as specified.



3. In a fruit-picker, the combination with the sectional adjustable handle, of the side pieces at the upper end thereof, the semicircular pieces secured to the side pieces, and the curved grabbers mounted on the semicircular pieces, the sack secured at its upper end to the side pieces, and the cross-pieces passed through the handle and connecting said side pieces, substantially as specified.

4. The herein-described fruit-picker comprising a handle, transverse rods passed through the handle near the upper end thereof, side strips secured to the ends of said rods, semicircular bands secured to the side strips at their upper ends and near their centers, grabbers arranged at right angles to said semicircular pieces and secured to each thereof and having their free ends curved forwardly, a transverse rod secured to the pole or handle at a distance from the first-mentioned cross-rods, and a sack secured to the lowermost semicircular band and to the side pieces and to the lowermost cross-rod, all substantially as herein shown and described.

605,462. WITHDRAWN.

605,463. WITHDRAWN.

605,464. CONTINUOUS SMELTING PLANT. WILLIAM S. REESE and EDWARD R. ARMSTRONG, Natrona, Pa., assignors to the Pennsylvania Salt Manufacturing Company, Philadelphia, Pa. Filed Mar. 30, 1897. Serial No. 629,905. (No model.)

Claim.—1. A continuous smelting plant comprising a smelting-furnace, a series of reducing-furnaces, a movable settler for the smelting-furnace arranged to discharge into any of the reducing-furnaces, settlers respectively arranged to receive the metal from each reducing-furnace, and means for tapping the charge from each receiving-settler into another furnace of the series.

2. A continuous smelting plant comprising an elevated smelting-furnace, a series of reducing-furnaces at successively lower levels, a movable settler for the smelting-furnace arranged to discharge into any of the reducing-furnaces, and settlers between and connected to the reducing-furnaces.

3. A continuous smelting plant comprising two elevated smelting-furnaces, a series of reducing-furnaces for each smelting-furnace, a movable settler for each smelting-furnace arranged to discharge into any of the reducing-furnaces therefor, and settlers located between and connected to the said reducing-furnaces.

4. A continuous smelting plant, comprising a smelting-furnace, a settler therefor, a series of reducing-furnaces having settlers between the same, and means for feeding the metal from any settler of the reducing-furnaces into any furnace of the series.

DESIGNS.

28,779. BADGE. WILLIAM LESLIE FRENCH, New York, N. Y. Filed Nov. 19, 1897. Serial No. 659,203. Term of patent 14 years.

Claim.—The design for an ornament or badge herein described and shown.

28,780. BADGE. FRANCIS H. MERRIMAN, Boston, Mass., assignor to the Sovereign Grand Lodge of the Independent Order of Odd Fellows, Baltimore, Md. Filed Mar. 22, 1898. Serial No. 674,228. Term of patent 14 years.

Claim.—The design for a badge or similar article, substantially as herein shown and described.

28,781. BADGE. CHARLES D. SPRAGUE, Minneapolis, Minn., assignor of one-half to Otto G. Bookworth, same place. Filed Oct. 26, 1897. Serial No. 656,370. Term of patent 7 years.

Claim.—The design for a badge, substantially as herein shown and described.

28,782. OFFICIAL CERTIFICATE. JAMES FRANK GRAFF, Baltimore, Md., assignor to the Sovereign Grand Lodge of the Independent Order of Odd Fellows, of Maryland. Filed Mar. 18, 1898. Serial No. 674,387. Term of patent 14 years.

Claim.—The design for an official certificate substantially as herein shown and described.

28,783. BOOK-COVER. ALBERT M. BOCKIUS, Philadelphia, Pa. Filed Apr. 15, 1898. Serial No. 677,750. Term of patent 3½ years.

Claim.—The design for a book-cover, substantially as herein shown and described.

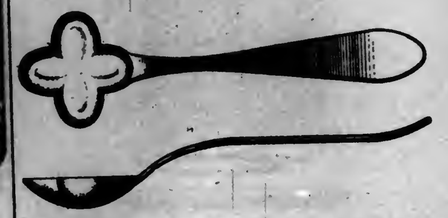
28,784. TRADING-STAMP. WILLIAM C. BROWN, Bridgeport, Conn. Filed Apr. 27, 1898. Serial No. 679,042. Term of patent 3½ years.

Claim.—The design for a trading-stamp, substantially as shown in the accompanying drawing.

28,785. WAFER. HENRY D. PERKY, Worcester, Mass. Filed Mar. 3, 1898. Serial No. 672,236. Term of patent 14 years.

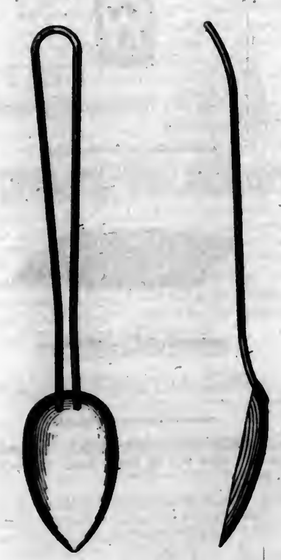
Claim.—The design for a wafer substantially as herein shown and described.

28,786. CIGAR OR SIMILAR ARTICLE. CHRISTIAN G. SINGLEY, Manheim, Pa. Filed Feb. 26, 1898. Serial No. 671,861. Term of patent 7 years.



Claim.—The design for a cigar, or similar article, substantially as herein shown and described.

28,787. PIPE. JULIUS ROCKER, New York, N. Y. Filed Apr. 26, 1898. Serial No. 678,804. Term of patent 3½ years.



Claim.—The design for a pipe or similar article herein shown and described.

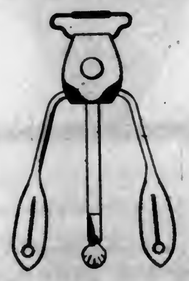
28,788. SPOON. HENRY H. WILLIAMS, Fort Wayne, Ind., assignor of one fourth to Franz Berger, same place. Filed Jan. 13, 1898. Serial No. 666,573. Term of patent 14 years.

Claim.—The design for a spoon or similar article substantially as shown and described.

28,789. SPOON. HENRY MOSER, Milwaukee, Wis., assignor to the Kieckhefer Brothers Company, same place. Filed Feb. 26, 1898. Serial No. 672,108. Term of patent 14 years.

Claim.—The design for a spoon substantially as herein shown and described.

28,790. BOTTLE. GEORGE MILLER, Jersey City, N. J. Filed May 9, 1898. Serial No. 680,227. Term of patent 7 years.



Claim.—The design for a bottle herein shown and described.

28,791. HAT-FASTENER. JOHN HOUGHTON CLARKE, Framingham, Mass. Filed June 9, 1897. Serial No. 640,071. Term of patent 14 years.

Claim.—The design for a hat-fastener, substantially as herein shown and described.

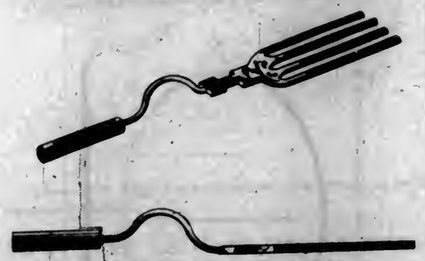
28,792. SUSPENDER-END. CHARLES F. EDGARTON, Shirley, Mass., assignor to the C. A. Edgarton Manufacturing Company, same place. Filed Mar. 14, 1898. Serial No. 673,570. Term of patent 14 years.

Claim.—The design for a suspender-end, substantially as herein shown and described.

28,793. SHOE-LACE FASTENING. BERNARD JOHNSON, Boston, Mass. Filed May 5, 1898. Serial No. 679,305. Term of patent 14 years.

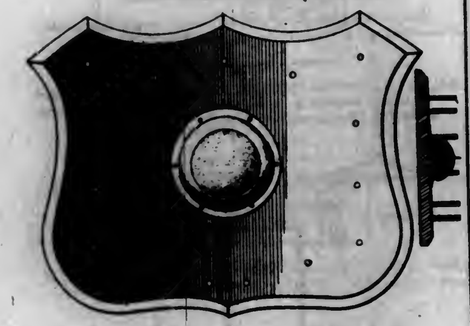
Claim.—The design for a shoe-lace fastening herein shown and described.

28,794. NECKTIE-SHIELD. FREDERICK H. ISAACS, Newark, N. J. Filed Sept. 13, 1897. Serial No. 651,544. Term of patent 14 years.



Claim.—The design for a necktie-shield, substantially as herein shown and described.

28,795. SKIRT-PROTECTOR. EMIL FISCHERHAUS, Philadelphia, Pa., assignor to the Wm. H. Horstmann Company, same place. Filed May 4, 1898. Serial No. 679,736. Term of patent 7 years.



Claim.—The design for a skirt-protector substantially as described and as shown in the accompanying drawing.

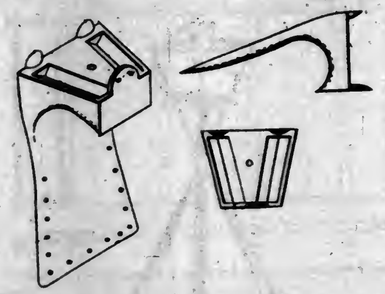
28,796. HAIR-CRIMPER MEMBER. ROBERT H. OGDEN, Poughkeepsie, N. Y. Filed Aug. 31, 1896. Serial No. 604,490. Term of patent 14 years.

Claim.—The design for a hair-crimper member, herein shown and described.

28,797. SPOOL-STAND. JAMES HAMILTON, Newburg, N. Y. Filed Jan. 6, 1898. Serial No. 665,856. Term of patent 14 years.

Claim.—The design for a spool-stand as herein shown and described.

28,798. KNIFE FOR OPENING SEAMS. PATRICK J. MCSHANE, Stapleton, N. Y. Filed May 6, 1898. Serial No. 679,964. Term of patent 7 years.



Claim.—The design for a knife for opening seams, substantially as herein shown and described.

28,799. SEAL-PRESS CASE. ALEXANDER H. MACKINNON, Olympia, Wash. Filed Apr. 6, 1898. Serial No. 676,962. Term of patent 14 years.

Claim.—The design for a seal-press case, substantially as shown and described.

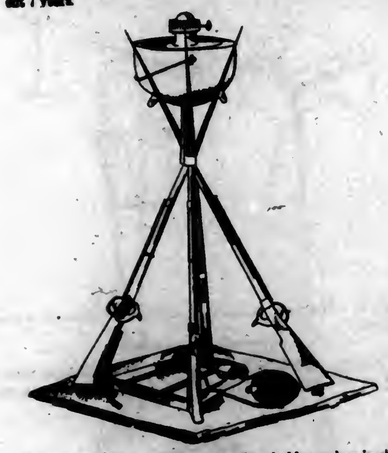
28,800. INSTEP-STIFFENER. LEWIS HAHN, Custer, S. D. Filed Jan. 21, 1898. Serial No. 667,402. Term of patent 14 years.

Claim.—The design for an instep-stiffener, as herein shown and described.

28,801. STAIR-CARPET BUTTON. ROBERT H. WARREN, Newark, N. J. Filed May 5, 1898. Serial No. 679,850. Term of patent 7 years.

Claim.—The design for a stair-carpet button, substantially as herein shown and described.

28,802. BEARING-SCREW FOR SHADE-ROLLERS. JACOB A. THOMAS, Reading, Pa. Filed Apr. 29, 1898. Serial No. 679,346. Term of patent 7 years.

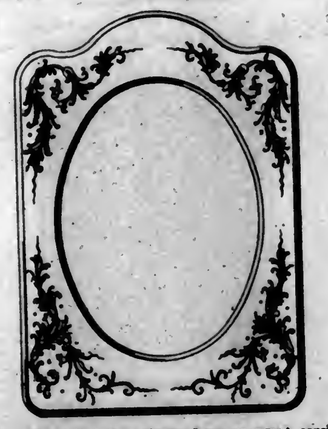


Claim.—The design for a bearing-screw for shade-rollers, substantially as herein shown and described.

28,803. GAS-BURNER. FRANK W. LAW, Pittsburg, Pa. Filed Mar. 26, 1898. Serial No. 675,198. Term of patent 14 years.

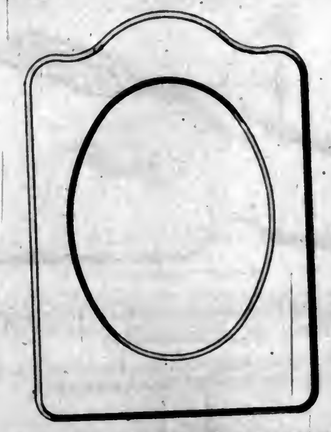
Claim.—The design for a gas-burner, substantially as herein shown and described.

28,804. LAMP STAND OR HOLDER. CHARLES H. SEBASTIAN, Boston, Mass. Filed Sept. 30, 1897. Ser'al No. 653,642. Term of patent 7 years.



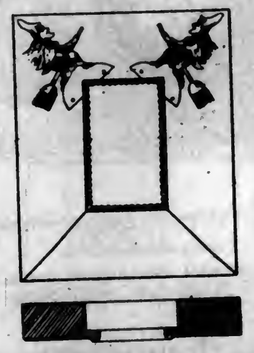
Claim.—The design for a lamp stand or holder as herein shown and described.

28,805. LAMP-BODY. CHARLES BURGESS, Rochester, N. Y., assignor to the C. T. Hess Manufacturing Company, same place. Filed Aug. 12, 1897. Serial No. 648,054. Term of patent 14 years.



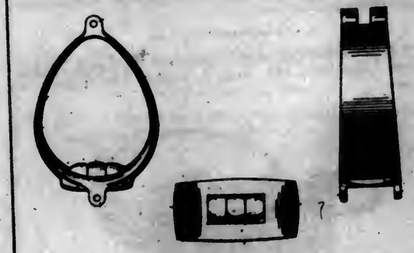
Claim.—The design for a lamp-body substantially as herein shown and described.

28,806. PICTURE FRAME OR MOUNT. MANUEL A. T. GILLESE, Philadelphia, Pa. Filed Apr. 6, 1898. Serial No. 676,704. Term of patent 7 years.



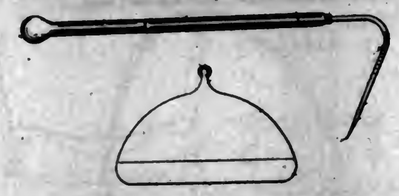
Claim.—The design for a picture frame or mount, consisting of a card having ornamentation thereon, substantially as herein described and shown in the accompanying drawing.

28,807. PICTURE FRAME OR MOUNT. MANUEL A. T. GILLESE, Philadelphia, Pa. Filed Dec. 17, 1896. Serial No. 616,973. Term of patent 7 years.



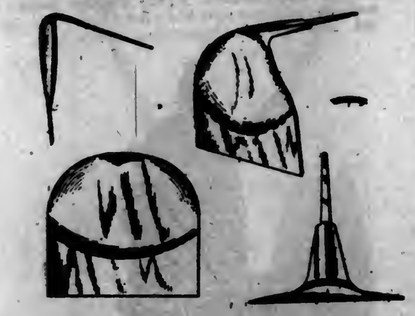
Claim.—The design for a picture frame or mount, substantially as described and as shown in the accompanying drawing.

28,808. PICTURE OR MIRROR FRAME. ANNIE H. GARDNER and WILLIAM H. GARDNER, Jr., Salem, Mass. Filed Jan. 20, 1898. Serial No. 667,243. Term of patent 7 years.



Claim.—The design for a picture or mirror frame as herein shown and described.

28,809. SHAFT-TUG. CHARLES WASHBURN, Chicago, Ill. Filed Apr. 18, 1898. Serial No. 678,067. Term of patent 7 years.



Claim.—The new and original design or useful shape for a shaft-tug substantially as herein shown and described.

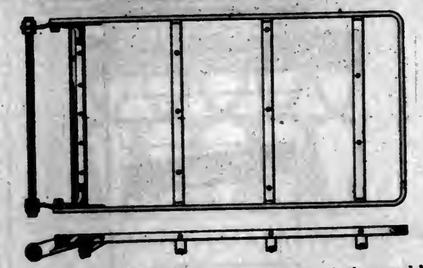
28,810. CORN-CUTTER. CHARLES HENRY SMITH, Park City, Mont. Filed Apr. 12, 1898. Serial No. 677,574. Term of patent 14 years.

Claim.—The design for a corn-cutter, substantially as herein shown and described.

28,811. HON. HENRY CLAY DOWD, Carthage, N. C. Filed May 5, 1898. Serial No. 679,893. Term of patent 14 years.

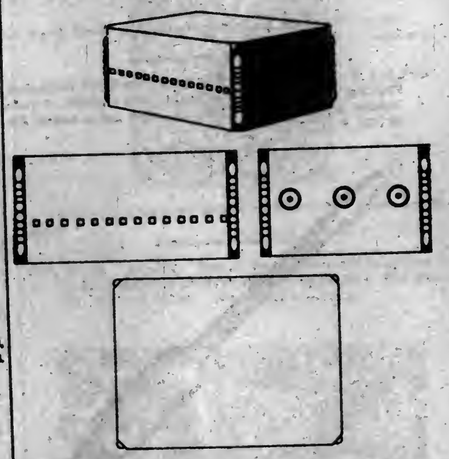
Claim.—The design for a bee herein shown and described.

28,812. LAWN-RAKE HEAD. FREDERICK H. KOEHLER, Canton, Ohio. Filed Oct. 31, 1896. Serial No. 610,705. Term of patent 7 years.



Claim.—The design for a lawn-rake head, as herein shown and described.

28,813. LAWN-RAKE HEAD. FREDERICK H. KOEHLER, Canton, Ohio. Filed Oct. 31, 1896. Serial No. 610,706. Term of patent 7 years.

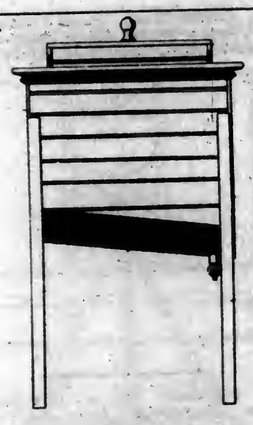


Claim.—The design for a lawn-rake head, as herein shown and described.

28,814. HARROW-FRAME. CHARLES S. SHARP, Auburn, N. Y., assignor to the D. M. Osborne & Company, same place. Filed July 2, 1897. Serial No. 643,689. Term of patent 14 years.

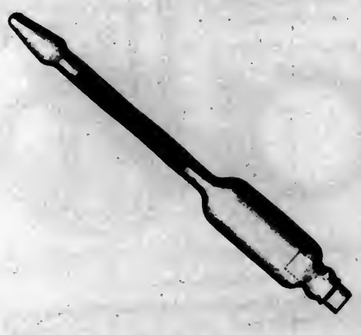
Claim.—The design for a harrow-frame as herein shown and described.

28,815. MEAT-BLOCK. WILLIAM J. HUFF, Decatur, Ill. Filed May 9, 1898. Serial No. 680,221. Term of patent 7 years.

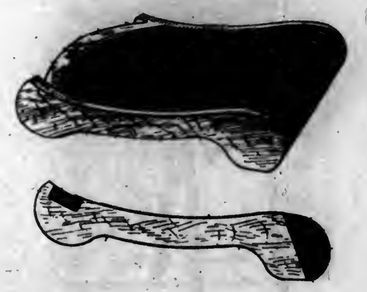


Claim.—The design for a meat-block substantially as herein shown and described.

28,816. CREAM-SEPARATOR. ARTHUR CLARE WIMMER, Knoxville, N. Y., assignor of one-half to Harvey Franklin Frost, same place. Filed Apr. 26, 1898. Serial No. 678,917. Term of patent 14 years.

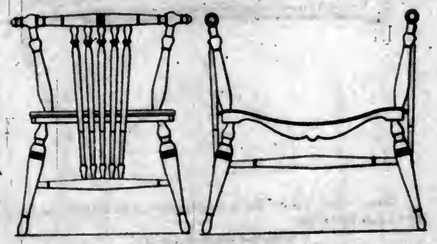


28,816.



Claim.—The design for a cream separator, as herein shown and described.

28,817. BUTYROMETER. NICHOLAS GERBER, Zurich, Switzerland. Filed Sept. 7, 1897. Serial No. 650,857. Term of patent 14 years. Patented in England Aug. 16, 1896, No. 19,283, and in Austria Mar. 14, 1897, No. 47/877.



Claim.—The design for a butyrometer, substantially as shown and described.

28,818. CHAIR-SEAT. JOHN FRAZE, Cochran, Ind., assignor to the Cochran Chair Co., same place. Filed Apr. 25, 1896. Serial No. 678,906. Term of patent 7 years.

Claim.—The design for a chair seat, substantially as shown and described.

28,819. CHAIR. WILLIAM THOMSEN, Port Washington, Wis., assignor to the Wisconsin Chair Company, same place. Filed May 10, 1898. Serial No. 680,235. Term of patent 7 years.

Claim.—The design for a chair, substantially as herein shown and described.

28,820. HEATING-STOVE. BRADLEY WOODWELL, Dunmore, Pa., assignor to the Scranton Stove Works, Scranton, Pa. Filed Feb. 25, 1898. Serial No. 671,899. Term of patent 14 years.

Claim.—1. In a design for a stove, the design for the base; substantially as shown and described.

2. In a design for a stove; the design for the top base-section D; substantially as shown and described.

3. In a design for a stove, the design for an ash-pit section; substantially as shown and described.

4. In a design for a stove, the design for the ash-pit door; substantially as shown and described.

5. In a design for a stove, the design for the body-section; substantially as shown and described.

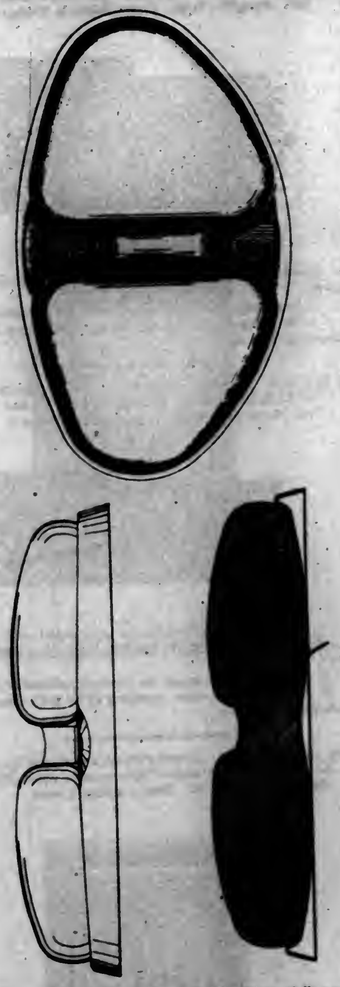
6. In a design for a stove, the design for the lower front door; substantially as shown and described.

7. In a design for a stove, the design for the upper front door; substantially as shown and described.

8. In a design for a stove, the design for the jacket; substantially as shown and described.

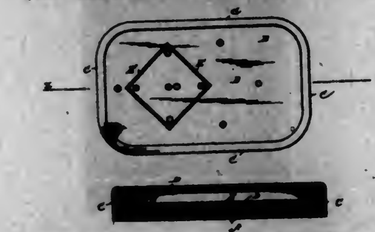
9. In a design for a stove, the design for the top ring; substantially as shown and described.

10. In a design for a stove, the design for the cover L; substantially as shown and described.



11. The design for a stove, as substantially herein shown and described.

28,821. GRATE-FRONT. JOSEPH F. HEWITT, Allegheny, Pa. Filed Nov. 11, 1898. Serial No. 611,722. Term of patent 7 years.

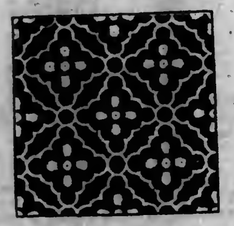


Claim.—The design for grate-front substantially as herein shown and described.

28,822. BICYCLE-SADDLE. JONATHAN A. HOYT, Westborough, Mass. Filed Apr. 8, 1898. Serial No. 676,963. Term of patent 14 years.

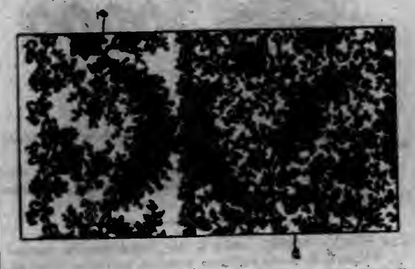
Claim.—The design for a bicycle-saddle substantially as shown and described.

28,823. GAME-BOARD. SAMUEL H. LEHMER, Springfield, Ohio, assignor to George S. Bowers and Albert Mates, same place. Filed Oct. 7, 1897. Serial No. 654,405. Term of patent 7 years.



Claim.—The design for a game-board, substantially as shown and described.

28,824. FRINGE. FRANK H. MAURER, Philadelphia, Pa., assignor to Joseph W. Maurer, William H. Maurer, Alexander G. Maurer, and Frank H. Maurer, same place. Filed Jan. 26, 1898. Serial No. 668,206. Term of patent 3½ years.

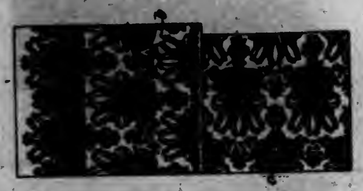


Claim.—The design for a fringe as herein shown and described.

28,825. TEXTILE FABRIC. HENRY STANTON LAWSON, Jersey City, N. J., assignor to the Fontanelle Leather Company, Passaic, N. J. Filed Apr. 25, 1898. Serial No. 678,807. Term of patent 7 years.

Claim.—The design for textile fabric as herein shown and described.

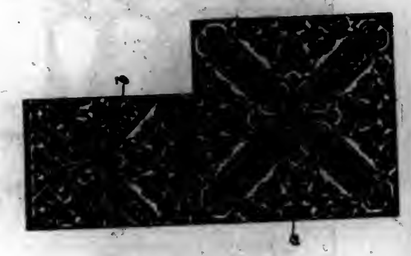
28,826. CARPET. ANNA K. MAY, Philadelphia, Pa., assignor to William H. McCallum and Irving McCallum, same place. Filed May 3, 1898. Serial No. 679,641. Term of patent 3½ years.



Claim.—1. In a design for a carpet, the body *a*, substantially as shown.

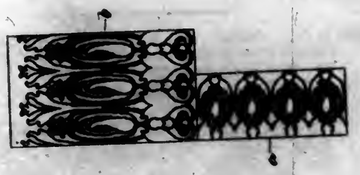
2. In a design for a carpet, the border *b*, substantially as shown.

3. The design for a carpet consisting of the body *a*, and border *b*, substantially as shown.



28,827. CARPET. ANNA K. MAY, Philadelphia, Pa., assignor to William H. McCallum and Irving McCallum, same place. Filed May 3, 1898. Serial No. 679,642. Term of patent 3½ years.

Claim.—1. In a design for a carpet, the body *a*, substantially as shown.



2. In a design for a carpet, the border *b*, substantially as shown.
3. The design for a carpet consisting of the body *a*, and border *b*, substantially as shown.

28,828. CARPET. ANNA K. MAY, Philadelphia, Pa., assignor to William H. McCallum and Irving McCallum, same place. Filed May 3, 1898. Serial No. 679,643. Term of patent 3½ years.

Claim.—1. In a design for a carpet, the body *a*, substantially as shown.
2. In a design for a carpet, the border *b*, substantially as shown.
3. The design for a carpet consisting of the body *a*, and border *b*, substantially as shown.

28,829. CARPET. ANNA K. MAY, Philadelphia, Pa., assignor to William H. McCallum and Irving McCallum, same place. Filed May 3, 1898. Serial No. 679,644. Term of patent 3½ years.

Claim.—1. In a design for a carpet, the body *a*, substantially as shown.
2. In a design for a carpet, the border *b*, substantially as shown.
3. The design for a carpet consisting of the body *a*, and border *b*, substantially as shown.

28,830. CARPET. ANNA K. MAY, Philadelphia, Pa., assignor to William H. McCallum and Irving McCallum, same place. Filed May 3, 1898. Serial No. 679,645. Term of patent 3½ years.

Claim.—1. In a design for a carpet, the body *a*, substantially as shown.
2. In a design for a carpet, the border *b*, substantially as shown.
3. The design for a carpet consisting of the body *a*, and border *b*, substantially as shown.

28,831. CARPET. ANNA K. MAY, Philadelphia, Pa., assignor to William H. McCallum and Irving McCallum, same place. Filed May 3, 1898. Serial No. 679,646. Term of patent 3½ years.

Claim.—1. In a design for a carpet, the body *a*, substantially as shown.
2. In a design for a carpet, the border *b*, substantially as shown.
3. The design for a carpet consisting of the body *a*, and border *b*, substantially as shown.

28,832. CARPET. ANNA K. MAY, Philadelphia, Pa., assignor to William H. McCallum and Irving McCallum, same place. Filed May 3, 1898. Serial No. 679,647. Term of patent 3½ years.

Claim.—1. In a design for a carpet, the body *a*, substantially as shown.
2. In a design for a carpet, the border *b*, substantially as shown.
3. The design for a carpet consisting of the body *a*, and border *b*, substantially as shown.

28,833. RUG. ADOLPH PRESSELA, Philadelphia, Pa., assignor to John H. Bromley and Edward Bromley, same place. Filed Apr. 30, 1898. Serial No. 679,403. Term of patent 3½ years.

Claim.—The design for a rug substantially as shown and described.

28,834. RUG. ROBERT H. ROMLEY, East Orange, N. J., assignor to John H. Bromley and Edward Bromley, Philadelphia, Pa. Filed Apr. 30, 1898. Serial No. 679,404. Term of patent 3½ years.

Claim.—The design for a rug, substantially as set forth.

28,835. CASKET-BODY. LEO SEMS and CLAYTON F. WHITNER, Bordentown, N. J., assignors to the National Casket Company, same place. Filed Feb. 26, 1898. Serial No. 672,697. Term of patent 14 years.

Claim.—The design for a casket-body substantially as herein described and shown.

28,836. CASKET-BODY. LEO SEMS and CLAYTON F. WHITNER, Bordentown, N. J., assignors to the National Casket Company, same place. Filed Feb. 26, 1898. Serial No. 672,698. Term of patent 14 years.

Claim.—The design for a casket-body substantially as herein described and shown.

28,837. CASKET-BODY. LEO SEMS and CLAYTON F. WHITNER, Bordentown, N. J., assignors to the National Casket Company, same place. Filed Feb. 26, 1898. Serial No. 672,699. Term of patent 14 years.

Claim.—The design for a casket-body substantially as herein described and shown.

28,838. CASKET-BODY. LEO SEMS and CLAYTON F. WHITNER, Bordentown, N. J., assignors to the National Casket Company, same place. Filed Feb. 26, 1898. Serial No. 672,700. Term of patent 14 years.

Claim.—The design for a casket-body substantially as herein described and shown.

28,839. CASKET-BODY. LEO SEMS and CLAYTON F. WHITNER, Bordentown, N. J., assignors to the National Casket Company, same place. Filed Feb. 26, 1898. Serial No. 672,701. Term of patent 14 years.

Claim.—The design for a casket-body substantially as herein described and shown.

28,840. CASKET-BODY. LEO SEMS and CLAYTON F. WHITNER, Bordentown, N. J., assignors to the National Casket Company, same place. Filed Feb. 26, 1898. Serial No. 672,702. Term of patent 14 years.

Claim.—The design for a casket-body substantially as herein described and shown.

TRADE-MARKS

REGISTERED JUNE 7, 1898.

81,647. PRINTED DRAPERY FABRIC. THE BRETTINGHAM MANUFACTURING COMPANY, Philadelphia, Pa. Filed Feb. 7, 1898.

GOBELIN

ART DRAPERY

Essential feature.—The words "GOBELIN ART DRAPERY" and the representation of a horseshoe and a four-leaf clover. Used since July 1895.

81,648. WOOLEN PIECE GOODS AND GARMENTS. LAW, RUSSELL & Co., Bradford, England. Filed Feb. 18, 1898.

Perramus

Essential feature.—The word "PERRAMUS." Used since August 22, 1892.

81,649. LININGS. J. W. GODDARD & SONS, New York, N. Y. Filed Apr. 11, 1898.

OPALESCENT

Essential feature.—The word "OPALESCENT." Used since January 1, 1897.

81,650. CERTAIN NAMED RUBBER GOODS. THE DIAMOND RUBBER COMPANY, Akron, Ohio. Filed Mar. 24, 1898.

SPHINX

Essential feature.—The word "SPHINX." Used since January 1, 1898.

81,651. CERTAIN NAMED RUBBER GOODS. THE DIAMOND RUBBER COMPANY, Akron, Ohio. Filed Mar. 24, 1898.

Essential feature.—The words and character "TITAN & SPHINX" and the representation of a sphinx. Used since January 1, 1896.

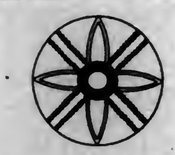
81,652. TOYS. PETER F. PIA, New York, N. Y. Filed Apr. 21, 1898.

Essential feature.—The representation of a teapot. Used since April 1, 1896

81,653. CERTAIN PAPER GOODS FOR HOTEL CHECKING SYSTEMS. JOHN T. HINES, Boston, Mass. Filed Feb. 26, 1898.

H S

C Co



Essential feature.—The letters and abbreviation "H. S. C. Co." Used since February 19, 1898.

81,654. PHOTOGRAPHIC PRINTING-PAPER. WESTERN CAMERA MANUFACTURING COMPANY, Chicago, Ill., and New York, N. Y. Filed Feb. 26, 1898.

ROYAL

Essential feature.—The word "ROYAL." Used since February 1, 1897.

81,655. CERTAIN PHOTOGRAPHIC APPARATUS AND MATERIAL. RADIOTYPE, LIMITED, London, England. Filed Mar. 22, 1898.

Essential feature.—A figure which represents the Assyrian symbol of the sun. Used since October, 1897.

81,656. STYLOGRAPHIC AND FOUNTAIN PENS. J. ULLRICH & Co., New York, N. Y. Filed Apr. 18, 1898.

Essential feature.—A heart-shaped figure with the letters, character, and abbreviation "J U & Co" arranged within it. Used since March 1, 1898.

81,657. PENS. A. S. ABERN & Co., New York, N. Y. Filed Feb. 7, 1898.

P.D&S.

Essential feature.—The letters and character "P. D. & S." Used since January 1, 1856.

81,658. BLACK INK. THADDEUS DAVIDS COMPANY, New York, N. Y. Filed Apr. 14, 1898.

MAGIC

Essential feature.—The word "MAGIC." Used since September, 1883.

81,659. CERTAIN NAMED CHEMICAL COMPOUNDS. FARBENFABRIKEN OF ELBERFELD COMPANY, New York, N. Y. Filed Apr. 13, 1898.

SAPHIROL

Essential feature.—The word "SAPHIROL." Used since March 1, 1898.

81,660. ANTISEPTIC PREPARATION. PER HAKANSSON, Enköf, Sweden. Filed Mar. 26, 1898.

SALUBRIN

Essential feature.—The word "SALUBRIN." Used since January, 1893.

81,661. MEDICINAL HERB COMPOUNDS PREPARED AFTER A CERTAIN NAMED SYSTEM. ELISABETH MEYER-RIEGK, Berlin, Germany. Filed Feb. 2, 1898.

Essential feature.—The representation of a medallion containing a branch of herbs and the letter "G." Used since April, 1897.

81,662. TONICS AND RESTORATIVES. MAX CRAMER, Boston, Mass. Filed Apr. 13, 1898.

Essential feature.—The word "CORPUSSANUM" and the representation of outspread wings surmounted by a burning torch. Used since April 1, 1896.

81,663. MEDICINAL TONICS. CHARLES TREVISANELLO, Newark, N. J. Filed Mar. 11, 1898.

ELISIR DELL'EREMITA

Essential feature.—The words "ELISIR DELL EREMITA." Used since January 1, 1897.

81,664. STOMACH-BITTERS. RAFFAELE NAPOLITANO, New York, N. Y. Filed Mar. 8, 1898.

Marshall

Essential feature.—The word "MARSHALL" and the representation of a shield surmounted by a machicolation tower. Used since February 15, 1898.

81,665. REMEDY IN TABLET FORM. ROBERT A. WALKER, Buffalo, N. Y. Filed Mar. 4, 1898.

BRAINERVINE

Essential feature.—The word "BRAINERVINE." Used since September 1, 1893.

81,666. PILLS. WILLIAM ANDREW PROUT, London, England. Filed Mar. 31, 1898.

BLAIR'S

Essential feature.—The word "BLAIR'S." Used since 1810.

81,667. HEMORRHOIDAL SUPPOSITORIES. WILHELM ERNST, Hanover, Germany. Filed Apr. 15, 1898.

Essential feature.—The words "ANUSOL HEMORRHOIDAL SUPPOSITORIES." Used since September 1, 1896.

81,668. ILLUMINATING-OIL. S. HOFFBURG & Co., New York, N. Y. Filed Apr. 19, 1898.

BRITELITE

Essential feature.—The word "BRITELITE." Used since March 23, 1896.

81,669. CIGARS. WILLIAM W. ARNOLD, Denver, Colo. Filed Jan. 28, 1898.

NATIONAL

Essential feature.—The word "NATIONAL," taken in connection with a large hotel building having a heavy cornice, a sloping roof, and a rectangular cupola in front extending above the roof. Used since October, 1897.

81,670. CEYLON TEA. ANDERSON BROS. & Co., New York, N. Y. Filed Mar. 29, 1898.

Essential feature.—The representation of a palm-tree inclosed within a circle. Used since March, 1897.

81,671. TEA. LONDON & JOHNSON, New York, N. Y. Filed Mar. 24, 1898.

OWL 

Essential feature.—The designation "OWL" represented by word or figure. Used since December 4, 1894.

81,672. ROLLED SHEET-GLASS AND WIRED GLASS. MISSISSIPPI GLASS COMPANY, St. Louis, Mo. Filed Apr. 11, 1898.

APPROBATUM M.G.CO.

Essential feature.—The word "APPROBATUM" and the letters and abbreviation "M. G. Co." Used since March 28, 1898.

81,673. EXPLOSIVES AND CARTRIDGES. EXPLOSIVSTOFF-WERKE SPIRALIT, GESELLSCHAFT MIT BESCHRÄNKTER HAFTUNG, Hamburg, Germany. Filed Feb. 12, 1898.

SPIRALIT

Essential feature.—The word "SPIRALIT." Used since August, 1893.

81,674. AMMUNITION FOR SMALL-ARMS. WINCHESTER REPEATING ARMS COMPANY, New Haven, Conn. Filed Apr. 4, 1898.

PIGEON

Essential feature.—The word "PIGEON." Used since March 23, 1898.

81,675. PIG-IRON. THE WOODSTOCK IRON WORKS, Anniston, Ala. Filed Jan. 5, 1898.

WIW

Essential feature.—The letters "W I W" either raised upon the surface of a casting of pig-iron or embedded therein. Used since March 1, 1897.

81,676. BICYCLES, TRICYCLES, AND VELOCIPEDES. SUPPLEE HARDWARE COMPANY, Philadelphia, Pa. Filed Mar. 30, 1898.

Essential feature.—The word "GIRARD." Used since January 1, 1895.

81,677. ENGINES AND THRESHING MACHINERY. J. I. CASE THRESHING MACHINE Co., Racine, Wis. Filed Mar. 5, 1898.

Essential feature.—The representation of an eagle with folded wings perched on a globe. Used since March, 1894.

THE NORRIS PETERS CO.

DECISIONS

OF THE

COMMISSIONER OF PATENTS

AND OF

UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

SCHMERTZ v. APPERT.

Decided March 22, 1898.

1. INTERFERENCE—FOREIGN PATENT—DATE OF REDUCTION TO PRACTICE—PRIORITY.

Appert took no testimony, but relied upon a French patent dated October 19, 1893, which was issued and published on January 12, 1894. Schmertz proved conception on January 10, 1894, and reduction to practice on January 17, 1894. *Held* that Appert's date of invention is January 12, 1894, the date of the publication of his foreign patent, and as there was no delay on Schmertz's part between the date of his conception and the date of his reduction to practice priority is awarded to Schmertz.

2. SAME—SAME—SAME.

It is the settled rule of the Office that it is the date of the publication of the foreign patent and not the date of the application therefor that controls in interference proceedings. (*De Ferranti* v. *Westinghouse, Jr.*, 82 O. G., 457; *Appert* v. *Parker*, 74 O. G., 1587.) This is also the rule of the courts. (*Am. Bell Telephone Co.* v. *Cushman et al.*, 65 O. G., 135.) The case of *Hanifen* v. *Godshalk* (79 O. G., 510) seems to hold the contrary; but the weight of authority is clearly as first above stated.

APPEAL from Examiners-in-Chief.

APPARATUS FOR AND PROCESS OF MANUFACTURING WIRE-GLASS.

Applications of Edmund C. Schmertz filed March 19 and April 1, 1895, Nos. 542,335 and 543,946. Application of Leon Appert filed April 27, 1894, No. 509,244.

Mr. William L. Pierce for Schmertz.
Messrs. Pollok & Mauro for Appert.

DUELL, *Commissioner:*

This is an appeal by Appert from the decision of the Examiners-in-Chief awarding priority of invention to Schmertz.

The issue in controversy is defined as follows:

1. The process of making glass sheets with wire inclosed therein, consisting in simultaneously forming a layer of glass and introducing wire thereto, and completing the sheet by forming another layer upon the first layer of glass, the process being carried on progressively.

2. An apparatus for making sheets of glass with wire inclosed therein, consisting of a table, a leading-roll to roll a layer of glass, means to support and introduce wire to the said layer, a second roll, behind the leading-roll, to form a layer of glass on the first or underneath layer, the periphery of the second roll being higher above the table than that of the leading-roll, and the two rolls being far enough apart to allow the glass for the second or upper layer to be poured between them.

Claims 4 and 5 of Schmertz's application No. 542,335 and claims 3 and 4 of his application No. 543,946 are put in interference with claim 1 of Appert's application under count 1 of this issue.

In the decision of the Examiners-in-Chief the meaning and scope of this issue have been referred to at length, and they have held that the second application of Schmertz does not claim the process of the issue and that there is no interference in fact between claims 3 and 4 of that application and claim 1 of Appert's application.

I am of the opinion, however, that the issue is and has been understood by the parties to the interference, and as both parties have accepted the issue as drawn by the Primary Examiner and as neither has presented a motion to dissolve it is not necessary to consider these matters here, but the interference will be determined on the issue as made and accepted.

Appert, the senior party, took no testimony to prove his case, but relied on Patent No. 233,528, taken out by him in France. This patent is dated October 19, 1893, and was issued and published January 12, 1894. It is stipulated that the invention described and claimed in Appert's application in this interference is the same invention described and claimed in the French patent, with the exception that the modified form of apparatus shown in Figs. 7 and 8 of the application in interference is not described in the French patent, but in a certificate of addition thereto dated April 6, 1894.

January 12, 1894, is therefore Appert's date of invention for the purposes of this controversy.

It is the settled rule of the Office that it is the date of the publication of the foreign patent and not the date of the application for it that controls in interference proceedings. (*De Ferranti* v. *Westinghouse, Jr.*, 52 O. G., 457; *Appert* v. *Parker*, 74 O. G., 1587.) This is also the rule of the courts. (*Am. Bell Telephone Co.* v. *Cushman et al.*, 65 O. G., 135.)

The case of *Hanifen* v. *Godshalk* (79 O. G., 510) seems to hold the contrary; but the weight of authority is clearly as first above stated.

Schmertz's alleged date of conception of the invention is June, 1893, when he states that he first made sketches and disclosed the invention to others. He also alleges that at subsequent times during July, 1893, from August 1, 1893, to December 1, 1893, and from January 1 to January 10, 1894, he made other sketches and explained the invention to others. His alleged date of reduction to practice is January 16, 1894.

The Examiner of Interferences and the Examiners-in-Chief held that the proofs show that Schmertz had a conception of the invention as early as July, 1893, and that he reduced it to practice on the 16th or 17th of January, 1894. The Examiner

of Interferences held that Schmertz did not exercise reasonable diligence in reducing to practice and awarded priority to Appert. The Examiners-in-Chief found, however, that during the week of January 5, 1894, Schmertz was taking steps to reduce the invention to practice, and as from that time to January 17, 1894, he used reasonable diligence in reducing to practice they reversed the Examiner of Interferences and awarded priority of invention to Schmertz.

The testimony on behalf of Schmertz is given solely from memory, and such testimony is, as usual, unsatisfactory. Without setting forth in detail the testimony in reference to the sketches claimed to have been made during the summer and fall of 1893 it is sufficient to state that after a careful examination of the same I do not consider the testimony sufficiently exact and positive to warrant a finding that Schmertz had a clear conception of the process and apparatus prior to 1894. However this may be, there is evidence in the case that satisfies me that prior to the reduction to practice claimed by Appert Schmertz had a conception of the invention in controversy.

Schmertz produces a sketch—"Schmertz Exhibit Trial Balance, January 1st, 1894"—which he testifies was made between January 1 and January 10, 1894. This sketch differs from the other exhibit sketches in that the two rolls are connected together, so that, as he states, other power than hand can be used in the operation of the apparatus. Hutchison identifies this exhibit and states that it was completed between the 1st and 10th of January, 1894; but his statements are made solely from memory and therefore can have little weight. Schmertz says that in order to carry out his invention the only additional apparatus required at the works in New Kensington beyond what was there and used in the manufacture of ribbed glass was one roll recessed at each end. As the Brownsville factory was not in operation, he concluded to obtain a roll from there, and on January 5, 1894, he telegraphed to the manager of the glassworks at Brownsville to ship a roll by steamer. This order was carried out, and the roll was received at Pittsburg on January 6, 1894, and taken to the works of the Scaife Foundry and Machine Company, where it was recessed at each end. The roll was then shipped to New Kensington on the 9th of January and received on the 10th. The telegram, the freight-bills, and Scaife's bill are offered as exhibits and fix these dates. The roll remained on the car until January 15, 1894, when it was taken into the factory and put on the casting-table in readiness to make wire-glass. On the 16th of January the apparatus was operated, and wire-glass was made by introducing wire behind the first roll. On the 17th glass was made by introducing wire in front of the leading or first roll. During the next few days about thirty sheets of glass were made by the apparatus carrying out this process.

Swearer identifies "Schmertz Exhibit Trial Balance, January 1st, 1894" as sketches shown to him by Schmertz prior to his (Swearer's) visit to the American Glass Company's works at Tacony, near Philadelphia, when they talked about this process and Schmertz told him that he intended to get a roll at their Brownsville factory. He left Pittsburg for Tacony on January 10, 1894, and left Philadelphia January 12, 1894, for Pittsburg, and on the 13th he was at the works at New Kensington. He first saw the roll which Schmertz had told him he proposed to order from the Brownsville factory on the siding of the Brownsville Plate Glass Company's works on Saturday, January 13, 1894, immediately on his return from Tacony. On Monday, January 15, 1894, he had this roll taken from the car to the works, where it was placed on the casting-table. On Tuesday, January 16, 1894, they began to make glass with the apparatus, including this roll. At this trial they made glass successfully by running the wire in over the front roll. Afterward they tried running the wire in under the front roll.

Toynbee, a ladler at the Brownsville Plate Glass Company's factory at New Kensington, testifies that when they began making wire-glass at that place the first roll used on the table had a recess at each end; that he first saw this roll on Monday of the week following Swearer's trip to Philadelphia; that on Tuesday, the next day, he saw it on a casting-table, and that on that day they used it in making wire-glass. He describes the operation of the apparatus and states that merchantable glass was made on that day by the method of this issue.

From this testimony I am of the opinion that between January 1 and January 10, 1894, Schmertz had a conception of the invention in controversy. Prior to January 12, 1894, he was taking steps to embody his conception in an operative machine, and on January 16 or 17 he had such a machine as the issue calls for, which was successfully operated and produced wire-glass by the process of this issue. Appert has taken testimony to show that the machine did not operate successfully. While the testimony shows that merchantable wire-glass was not made in every instance, yet such glass was made at times, and it is clear that the reasons why it was not made in every instance were understood by the parties who were operating the apparatus, all of whom were expert glass-makers. The reasons of the failures are specifically and fully explained by Swearer. Without going into the details on this point, it is held that the machine was operated successfully to carry out the process of the issue and that what was done was an actual reduction to practice. Although this reduction to practice was later than that claimed by Appert, yet as Schmertz was the first to conceive and used reasonable diligence in reducing his invention to practice it is held that he is the first inventor.

It has been urged on behalf of Appert that Schmertz never conceived the invention and that he and his witnesses have conspired to give such testimony as would defeat Appert's claim to invention and have intentionally testified falsely and changed and added to the exhibits in the case; but I agree with the conclusions of the lower tribunals that there is no justification in the record

for this contention. It is also contended on behalf of Appert that Schmertz conducted the prosecution of his applications and of this interference proceeding in a deceitful and misleading manner; but I find no warrant for these contentions.

The decision of the Examiners-in-Chief in awarding priority to Schmertz is affirmed.

EX PARTE JENKS.

Decided April 29, 1898.

DESIGN—DESCRIBING PREFERRED FORMS OR MODIFICATIONS.

Words or phrases referring to or describing preferred forms or modifications of designs should not be permitted in an application for a design. Modifications of designs do not exist, and applicants should restrict their drawing and description to one design.

ON petition.

DESIGN FOR CANDELABRA.

Application of Barton P. Jenks filed May 15, 1897, No. 636,795.

Mr. A. P. Browne for the applicant.

DUELL, *Commissioner:*

This is a petition from the action of the Examiner requiring the cancellation of certain matter from the specification.

In describing the design applicant states in his specification that—

> two of the opposite panels are preferably left plain while the other two are given an ornamentation hereinafter more particularly described. * * * Two of the opposite panels are preferably left unornamented. * * * To form the entire candlestick the body portion just described may be united to another portion C, similarly shaped, but preferably shortened in its vertical dimensions. Except for the change in its vertical dimensions, the body portion C is formed on substantially the same lines as the body portion A. The ornamented panels of said portion C may, however, be modified if desired by fluting them to correspond with the ribs and depressions c^x and c^4 as shown. The upper portion of the body C is contracted into a neck portion c', which is provided with a flaring mouth c^3. The base B preferably has its horizontal lines similar to those of the body portion as shown in Fig. 2, and its edge may be scalloped as shown at *b*. Each of the body portions A and C may be provided at its bottom with an ornamental beading *m*, *m'* as shown.
>
> I do not consider my design to be limited to the form of base shown, nor to a candlestick formed of the two body portions A and C used unitedly, as a candlestick may be formed of either of said body portions combined with any desired form of base or support, my design residing primarily in the contour and ornamentation of the body portion as shown in either of the forms A and C.

The Examiner has required that the word "preferably" where it occurs in this description, the sentence "The ornamented panels of said portion C may, however, be modified if desired by fluting them to correspond with the ribs and depressions c^x and c^4 as shown," and the last paragraph of that part of the specification above quoted be canceled and that the words "may be" be changed to the word "*is*."

The Examiner's objection to this part of the specification is substantially that it sets forth preferred forms or modifications of the design not shown. I think the Examiner's objection is well founded. It seems clear to me that by having this matter in the specification applicant does not intend to confine his description to one design, but this matter is placed in the description so that the specification will be broad enough to refer to modifications of the design not shown.

As was said in the case of *ex parte Hill and Renner*, (82 O. G., 1968,) there is abundant authority for holding that modifications of designs do not exist and should not be shown and described in one patent, and the decisions of this Office require applicants to restrict their drawings and description to one design, leaving out all reference to modifications. See in addition to *ex parte Hill and Renner*, *ex parte Coe* (81 O. G., 2086) and *ex parte Brand*, (83 O. G., 747.)

The requirement of the Examiner is sustained and the petition is denied.

EX PARTE MERIWETHER & COMPANY.

Decided May 21, 1898.

1. TRADE-MARK—"PEACH GREENVILLE."

The words "Peach Greenville" refused registration as a trade-mark for plug-tobacco on the word "Peach," previously registered, as it is not a safe practice to permit the registration of a compound trade-mark, one of the distinguishing features of which has already been registered, as purchasers using ordinary caution might easily be deceived.

2. SAME—REGISTERING DECEPTIVE TRADE-MARKS CONDEMNED.

The Patent Office should not give its stamp of approval to a class of trade-marks the use of which has a tendency to mislead or deceive the public, and thus take a position antagonistic to well-settled rules of law.

ON petition.

TRADE-MARK FOR PLUG-TOBACCO.

Application for registration filed September 29, 1897, No. 54,868.

Messrs. C. A. Snow & Co. for the applicants.

DUELL, *Commissioner:*

Registration having been refused for the words "Peach Greenville" as a trade-mark for plug-tobacco, applicants have taken this appeal, and in an elaborate brief have sought to show that the action of the Examiner was erroneous and therefore should be reversed on appeal.

It appears that the word "Peach" as a trade-mark for plug-tobacco, etc., was registered in 1884, based upon a use from 1845. Registration has been refused upon this mark and upon the ground that the word "Greenville" is geographical. That the word "Greenville" is geographical cannot be successfully controverted, for the reason that it appears from the *United States Official Postal Guide* that there are some thirty post-offices of that name in the United States; but I do not base my decision in this case upon the geographical character of the word "Greenville."

Applicants seek to register a compound mark, and the rule which should control in such cases is well set forth in *Bush & Co.*, (10 O. G., 164,) in which the Commissioner held that it was not—

> a safe practice to permit the registration of a compound trade-mark, one of whose distinguishing features has already been registered.

A cursory examination of the decisions of this Office relative to the registration of trade-marks shows many instances in which the correct practice above referred to has been followed. The words "Golden Star" were refused registration in view of a prior registration showing the word "Star" and the representation of a star. Registration of the words "Railway Timekeeper" and the representation of a locomotive was refused in

view of the prior registration of the word "Railway" and of the fact that the word "Timekeeper" was descriptive of the article to which the mark was applied. The word "Puff" was refused registration in view of the previously-registered words "Opera Puff." The words "Black Swan" were refused registration in view of the prior registration of the word "Swan."

It has also been held by the Office that the word "Royal" was infringed by the use of the words "Royal Dutch." It was stated in the case then under consideration that the word "Royal" was the essential part of the trade-mark, while the word "Dutch" was merely descriptive. The words "Old Taylor" were refused registration on the prior registration of the word "Taylor." The words "Royal-Salted-Codfish," with hyphens between the words, were refused registration in view of the prior registration of the word "Royal."

As I view it, if a call were made for "Peach" tobacco it could properly be filled by handing the customer the "Peach Greenville" brand. In other words, the purchaser using ordinary caution could easily be deceived.

In *ex parte Caire*, (15 O. G., 248,) in which registration was refused of the words "Black Swan," the Commissioner thus correctly enunciated the law as repeatedly held by the courts relative to the class of purchasers to be protected against misleading trade-marks.

It has been held that even if wholesale buyers are not misled, but retailers or consumers are, by the resemblance which one mark bears to another, the right of action exists.

He also said, citing various authorities:

And it has also been held that if a mark is calculated to mislead, even if no one has actually been deceived, the courts will presume the resemblance to be not accidental, but intentional, and for the purpose of deception, and for this purpose the whole trade-mark need not have been counterfeited.

This Office should not give its stamp of approval to a class of trade-marks the use of which has a tendency to mislead or deceive the public, and thus take a position antagonistic to well-settled rules of law.

I am clearly of the opinion that the words should not be registered, and the action of the Examiner refusing registration is affirmed.

DECISIONS OF THE U. S. COURTS.

Court of Appeals of the District of Columbia.

MCCORMICK *v.* CLEAL.

Decided February 24, 1898.

1. INTERFERENCE—PROVING DATES—REFRESHING MEMORY BY DOCUMENTS—PRODUCING DOCUMENTS.

It is not necessary that documents from which a witness may have refreshed his memory as to dates be produced at the examination; but the failure to do so would often cause the facts to be regarded as of little weight. When produced and used to assist the memory, they need not be offered as evidence, and in a majority of instances they would be inadmissible if offered.

2. SAME—REDUCTION TO PRACTICE—DRAWINGS.

Perfected drawings showing an invention cannot be regarded as a reduction to practice of the invention.

3. SAME—REDUCTION TO PRACTICE—DILIGENCE.

The question of diligence cannot be determined by any general rule applicable to all cases, but necessarily depends upon the special circumstances of each case as it arises.

4. SAME—DILIGENCE—PRIORITY.

Cleal's conception and reduction to practice is the date of his application, July 6, 1894. McCormick prepared two applications for patent in February, 1894. One he filed on March 5, 1894, for what is called "machine No. 4." The other application, the one involved in this interference, under which "machine No. 3" had been begun but laid aside for No. 4, was not filed until October 6, 1894. On April 8, 1894, he began "machine No. 5," which contained the locking mechanism of No. 4 and differs from the mechanism of the issue merely in the time of the operation of the two sets of keys, in the issue the department-key being first pressed and the cash-key thereby unlocked, while in machines Nos. 4 and 5 the cash-keys are first pressed and the department-keys thereby unlocked. *Held* that machine No. 3 fell short of being a reduction to practice; but as, judging by McCormick's actions, he neither saw the superiority of one mode of operation over the other at the time he was working on the machines nor apprehended that there was a substantial difference between the functions of the mechanism in merely reversing the time of the locking action upon the distinct sets of keys, the locking device being the important improvement, and he appreciating its value, though he may have been mistaken as to the most advantageous mode of its operation and may also for a time have supposed that it was the same invention when operated reversely, also *Held* that under such circumstances what McCormick was doing during the eight months from the date of preparing his application to the filing of it in the Patent Office was not unreasonable delay, and priority awarded to him over Cleal.

Messrs. Staley & Shepherd for the appellant.
Mr. Edward Rector for the appellee.

SHEPARD, *J.*:

1. This is an interference proceeding in the matter of an improvement in department cash-registers, and the controversy is on the following issue:

In a cash-register, the combination of a series of numbered keys representing different amounts, a series of special keys, and locking means controlled by the special keys to prevent operation of the numbered keys until a special key has been operated.

The object of the "department" cash-register is to preserve in a single machine distinct and separate records of the sales of different classes of articles. For example, in a drug-store there may be special departments, say, of drugs, of soda-water, cigars, etc.

Registers called "department-machines" were old when the invention in controversy was made. In these there were provided separate registering mechanisms for each department, which were operated by special keys appropriately labeled. There is one set of numbered keys called "cash-keys." In order to register a sale in the proper department, it is necessary that the register assigned thereto shall be thrown into coöperation with the cash-keys before the registration can take place. If, therefore, a department-register is not thrown into coöperation, as aforesaid, the amount of the sale expressed on the cash-key will not be added upon the same, and so, the cash-keys being free to operate whenever pressed, if at the end of an operation of the machine any one of the department-registers shall be left in position to coöperate with the cash-keys the registration will take place therein, whether it be the appropriate one or not.

2. The improvement in the invention in controversy consists in the introduction of a locking device between the different sets of keys, whereby the operation of the cash-keys is prevented until the special department-register has been thrown into coöperation. The cash-keys are normally locked and can only be operated when a department-key is pressed and the register thrown into coöperation. There is a connection between the locking device and the department-keys by which the latter in moving the register unlock the cash-keys and thus permit of their operation.

3. The applications for patents for this improvement out of which the interference grew were filed three months apart. The first was filed by appellee, Joseph P. Cleal, July 6, 1894; the second by the appellant, John H. McCormick, October 6, 1894. Cleal's application is a constructive reduction to practice and must be taken also as the date of his conception, because he has introduced no evidence in respect thereof. McCormick, being the junior applicant, had the burden of showing conception before Cleal's date of filing, together with reduction to practice, or such diligence in following up his conception as will support his right founded thereon.

4. The Examiner of Interferences and the Examiners-in-Chief on appeal from him awarded priority to McCormick on the ground that he was the first to conceive and had not been wanting in diligence in reduction to practice.

The Commissioner reversed the decision of the Examiners-in-Chief and awarded priority to Cleal. He was of the opinion, first, that McCormick's evidence of conception was not satisfactory, and, second, that had he conceived as alleged he would have lost his right for lack of diligence in reduction to practice.

McCormick had been at work upon cash-registers since 1892 and claims to have conceived the idea of the locking device of the issue in or about October, 1893. He claims that he explained it to others in December, 1893, and made drawings illustrating it about the same time.

The doubt of the Commissioner in respect of this claim of invention is founded on the evidence concerning these first drawings, called 1 and 2. These illustrate several features of complicated department-machines. No. 2 is in ink and pencil. The part in ink is said to have been traced from or after No. 1. The part in ink does not show the detail of the subject-matter of the controversy at all. That appears in a pencil sketch added to the ink drawing some time after its execution. Appellant's witnesses did not explain when this pencil sketch was added and they were not cross-examined with regard to it. Those witnesses were not contradicted or impeached. Giving them credence, as we must, the testimony is overwhelming that this detail was in drawing No. 2 in February, when the drawings were made for use in the Patent Office and the specifications were prepared in the office of appellant's solicitor. These latter dates were fixed with certainty by the draftsman, by a mechanic who worked on the McCormick machines, two stenographers, and the solicitor, as well as by McCormick himself. Dates were fixed by the solicitor's office records and the note-books of the two stenographers. The mechanic assisted his memory by a receipted bill for certain patterns made for his use, and the draftsman testified to referring to drawing No. 2 in preparing the drawings and identified two "blue-prints" made at the time as copies thereof. The note-books, records, bill, and blue-prints were not offered in evidence, and for that reason the Commissioner was of the opinion that the proof of dates by reference to them should be disregarded. This view is clearly erroneous. It is not even necessary that documents from which a witness may have refreshed his memory be produced at the examination; but the failure to do so would often cause the evidence to be regarded as of little weight. When produced and used to assist the memory, they need not be offered as evidence, and in the majority of instances they would be inadmissible if offered. (1 Greenl. Ev., sec. 437; *Commonwealth* v. *Ford*, 130 Mass., 64, 66; *White* v. *Tucker*, 9 Iowa, 100.)

The documents referred to by the witnesses were all produced, as the record shows. Counsel for the appellee had an opportunity to inspect them and to cross-examine the witnesses in respect of them. He did not cross-examine, and it does not appear that he inspected the instruments; but the record does not show that he offered or asked leave to do so. So far as that shows any action by him it is that he objected to the reference to them on the ground that they were secondary evidence. We cannot indulge any other presumption from his conduct than that he was at the time satisfied in respect of the genuineness of the records and of their dates.

On this issue our conclusion necessarily is that McCormick conceived the idea of the invention in controversy, communicated it to others, and made a satisfactory drawing illustrating it as early at least as February, 1894.

5. Appellant's claim that the perfected drawings showing forth his invention must be regarded as a reduction to practice is inadmissible. Unless he can show an actual reduction to practice or diligent endeavor to that end commencing before his rival's application was filed and continuing to the date of filing his own the decision must be against him.

It appears from the evidence that McCormick did not make a machine embodying this particular detail before Cleal's date of application. He worked on a machine which is called "machine No. 3" in the testimony; but he did not make and attach the locking device thereto. The construction admitted of the attachment and seems to have been made with that view. Machine No. 3, then, was not a reduction to practice. Of his two sets of specifications made in February, 1894, for applications for patents he filed one on March 5, 1894, for what is called his "machine No. 4," upon which he has obtained a patent. The specifications under which No. 3 had been begun are those contained in the application in interference, which, as

we have seen, was not filed until October 6, 1894. "Machine No. 5" was begun by McCormick in April, 1894, and finished some time during the summer. This differed from No. 4 in the mechanism of the drawer in respect of its action in opening and closing and in some other details not affecting the matter at issue. Both had the same locking device, however, operating in the same way. In each the department-keys are normally locked, and the cash-keys are free. The operation is first to press in the cash-key. This does not register, but sets the machine so that when a department-key is pressed the registration takes place.

In the issue of the interference the specific description is—

a locking means controlled by the special keys to prevent operation of the numbered keys until a special key has been operated.

This means a mechanism whereby the cash-keys are kept locked until the department-key is pressed in. Here the department or special key sets the machine for registration and unlocks or releases the cash or numbered keys, so that when pressed in the desired registration is accomplished.

It appears that the locking mechanism of the issue aforesaid and those of machines 4 and 5 are alike. They differ merely in the time of the operation of the two sets of keys. The operation of one is simply reversed in the other. In the former the department-key is first pressed, and the cash-keys are thereby unlocked. In the latter the cash-keys are first pressed, and the department-key is thereby unlocked. The change in the time of the operation is by a process requiring nothing more than ordinary mechanical skill. The locking of the keys is accomplished by means of a hook attached to a rod, and the change in the time is worked by a change of the hook. If this hook engages at the bottom, the keys are locked before the operation; if at the top, they are locked afterward.

Notwithstanding the conditions shown above, each tribunal of the Patent Office agreed in holding that on account of the state of the art and the terms of the applications—

the words of the issue, [as said by the Commissioner,] instead of being a mere statement of function, are a specific limitation of the claim to means to control the numbered keys until the special key is operated.

We are not satisfied of the correctness of this view, but will pass the point, because its determination is not necessary in our view of the question of diligence. There was no testimony from the mechanical experts on the point beyond that of McCormick himself, and to go into the question would involve the consumption of much space in the discussion of the descriptions contained in the elaborate specifications of each application.

6. This brings us to the consideration of the final question: Did McCormick lose the advantage of his earlier conception through lack of diligence in reduction to practice before his rival's application was filed? This question of diligence cannot be determined by any general rule applicable to all cases. It necessarily depends upon the special circumstances of each case as it arises. Now if we had nothing else in the case than the fact that McCormick made the invention and had his drawings and specifications prepared as early as February 20, 1894, and yet withheld them from the Patent Office for about eight months, we would be compelled to decide against him, for no ample excuse for delay can be found in the situation and conditions of the parties or the business engagements of their solicitor apart from other considerations. (*Dodge* v. *Fowler*, 82 O. G., 595.)

In our opinion, however, there are other important considerations that tend to excuse the delay.

As we have seen, McCormick began with sufficient promptness the construction of his machine No. 3, with the intent to apply therein the locking device of his drawing No. 2 in the very manner described in the issue. This fell short of being a reduction to practice, because he did not in fact apply the mechanism thereto. He had also worked on machine No. 4, and the Patent Office drawings were drawn therefor and the application was speedily filed. In the meantime No. 3 was laid aside for No. 4, which contained some additions respecting the operation of the machinery of the registers in connection with the cash-drawer that were novel and supposed to be valuable. Reversing the action of the locking mechanism between the keys from that contemplated in the proposed construction of No. 3 was caused by the changes in the aforesaid action of the registering machinery in coöperation with the drawer. Part of the machinery used in No. 4 was taken off and used in machine No. 5, which was supposed to improve thereon in some slight particulars. The operation of the locking machinery was the same in No. 5 as in No. 4 and for the same reason.

Conceding, as we have done, that there may be a substantial difference of means in the different times of the operation of the locking device upon the cash-keys as carried out in machines 4 and 5 and in the machine of the issue, and conceding, further, that the latter mode of operation is superior, yet it does not appear that this superiority was then apparent.

Judging by the action of McCormick we may conceive that he neither saw the superiority of one mode of operation over the other at the time nor apprehended that there was a substantial difference between the functions of the mechanism in merely reversing the time of the locking action upon the distinct sets of keys. He was certainly diligent in constructing and perfecting his machine along the line of its then apparent importance to him. The locking device was the important improvement. He appreciated its value, though he may have been mistaken as to the most advantageous mode of its operation, and may also have for a time supposed that it was the same invention when operating reversely.

In the light of these circumstances we cannot regard his delay as inexcusable. It would be unjust to do so. Some reasonable indulgence where lapse of time only is in the way ought to be extended to an inventor who was thus engaged in perfecting and attempting to bring out all of the merits of his invention.

For the reasons given we are of the opinion that priority should be awarded to the appellant.

The decision appealed from will therefore be reversed, and the proceedings and decision of this court will be certified to the Commissioner of Patents, as required by law. It is so ordered.

"The following words 'or again, if desired, to the same extent,'" in lines 59–60 of the printed specification.

Notice to Show Cause.

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
Washington, D. C., May 7, 1898.

The following notice to show cause is published in the OFFICIAL GAZETTE for the reason that it has been found impracticable to serve notice in the usual way, a registered letter containing notice to the same effect, mailed to Mr. Holgate at his last-known address, having been returned with the report that it could not be delivered.

To George H. Holgate, doing business under the name of the Association American Inventors, last known address Betz Building, Philadelphia, Pennsylvania, present address unknown:

SIR: Copies of charges filed against you as representative of the Association American Inventors by the following-named persons were sent you on the dates mentioned below, and you were given until February 12, 1898, to answer the same, if you desired to do so:

I. N. Fickes, of Holland, Kans.....January 21, 1898.
Nathan Lloyd, of Greenbrier, Mo.....January 22, 1898.
J. L. Zeiger, of Cleveland, Ohio .....January 28, 1898.
John McWilliams, of Egypt Mills, Mo ..February 5, 1898.

You were informed in the letters accompanying the charges of McWilliams, Lloyd, and Fickes that, inasmuch as you were not registered as a patent attorney, disbarment proceedings would not be instituted. It has been determined, however, that inasmuch as you still represent a number of applicants before this Office in applications filed before the 1st of January, 1898, as is shown by a list of such cases filed by your representative on January 14, 1898, and in which registration was waived, said list numbering 171 cases, you are practicing before the Office and within the provisions of the statute you are subject to disbarment proceedings. In view of this fact and in view of the fact that in some of the foregoing cases the filing of the answer was made optional with you you are hereby required to show cause on or before the 15th day of June, 1898, in each of these cases, why you should not be disbarred from practice and why the Commissioner of Patents should not refuse to recognise you as patent agent in accordance with the statutes in such cases made and provided.

C. H. DUELL,
Commissioner.

Roster of Registered Attorneys.

As an alphabetical list of the individuals and firms registered in this Office under the provisions of Rule 17 of the Rules of Practice, as amended August 6, 1897, is about to be published, it is directed that one copy of such list be furnished to each registrant free of charge, and that copies be furnished to the public at the nominal price of five cents each, a five-cent coupon being acceptable in payment therefor. One copy of each subsequent edition will be furnished gratuitously to each registrant whose name appears thereon for the first time in any edition.

Registrants are requested to give notice of any errors that may have occurred in the list as published.

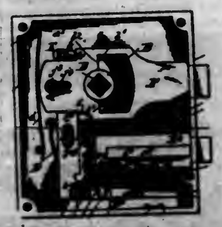
PATENTS

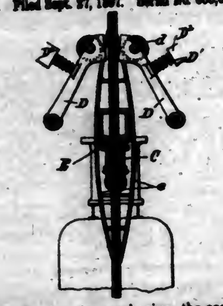
GRANTED JUNE 14, 1898.



605,465. SKIRT-SUPPORTER. MILDRED M. ANDERSON, New York, N. Y. Filed July 31, 1897. Serial No. 646,043. (No model.)

Claim.—1. As an improved article of manufacture, a skirt-supporter, comprising a removable clip for attachment to the waist, and a hook for attachment to the skirt, said clip consisting of an inner member having headed studs on its outer face, and an outer member, having open slots adapted to engage the stems of the respective studs when the fabric of the waist is clamped between the clip members, and having also a keeper to receive the hook on the skirt.

2. The combination with a hook to be secured to a dress-skirt, of a clip adapted to be removably secured to the dress-waist for supporting the skirt, said clip comprising the inner member A, provided with headed studs *a'* on its outer face, and the outer member B, consisting of a plate *b*, having in its lower edge open slots *b'*, spaced to engage the studs on the inner member A, and keepers *b²*, on its outer face to receive the supporting-hooks on the skirt, substantially as set forth.



605,466. LOCK. ANGUS H. BARNES, Reno, Nev. Filed Mar. 20, 1897. Serial No. 628,748. (No model.)

Claim.—1. In a lock, the combination with a case having a keyhole, of a horizontally-sliding latch-bolt provided on its under side with a shoulder *f*, a vertically-sliding tumbler adapted in its raised position to engage said shoulder and hold the latch-bolt from inward movement, a horizontally-sliding lock-bolt below the latch-bolt and above the keyhole and on the same side of the vertically-sliding tumbler as the keyhole, and a horizontally-sliding lock-bar below the keyhole of a length when thrown back to extend under the vertically-sliding tumbler when the latter is raised and hold it in engagement with the shoulder *f*, said lock-bolt, tumbler, and lock-bar adapted to be operated by a key in said keyhole, substantially as described.

2. In a lock, the combination with a case having a keyhole, and the latch-bolt, of a sliding lock-bolt situated between the latch-bolt and the keyhole, a sliding tumbler moving in a direction substantially at right angles to that of the lock-bolt and adapted to hold the latch-bolt from inward movement, and a sliding lock-bar situated on the side of the keyhole opposite the lock-bolt and moving in a direction parallel with that of the lock-bolt and adapted to hold the sliding tumbler from movement, said lock-bolt, tumbler and lock-bar being adapted to operate by the key.

605,467. ELEVATING MECHANISM. OREN G. BRATTY, Cleveland, Ohio. Filed Sept. 27, 1897. Serial No. 653,099. (No model.)

Claim.—1. In elevating mechanism, the combination of an elevator-car, an elevator-shaft, a screw extending longitudinally in said shaft, a nut secured to said car and meshing with said screw, means for rotating said nut, and means for bracing said screw between its extremities, substantially as set forth.

2. In elevating mechanism, the combination of an elevator-car, an elevator-shaft, a screw extending longitudinally in said shaft, a nut secured to said car and meshing with said screw, means for rotating said nut, means for bracing said screw between its extremities and means for removing said bracing means on the passage at the braced point, of the said nut, substantially as set forth.

3. In elevating mechanism, the combination of an elevator-car, an elevator-shaft, screw extending longitudinally in said shaft, a nut secured to said car and meshing with said screw, means for rotating said nut, separable means for bracing said screw at points intermediate of the extremities thereof, and means for separating said bracing means thereby permitting the passage on said screw of said nut, substantially as set forth.

4. In elevating mechanism, the combination of an elevator-car, an elevator-shaft, a screw extending longitudinally in said shaft, a nut secured to said car and meshing with said screw, means for rotating said nut, pairs of bracing-levers located at intervals along said screw, a separator secured to the car on each side of said nut, whereby said levers are separated on the approach of said nut, substantially as set forth.

5. In elevating mechanism, the combination of an elevator-car, an elevator-shaft, a screw extending longitudinally in said shaft, a nut secured to said car and meshing with said screw, means for rotating said nut, pairs of bracing-levers located at intervals along said screw and journaled to the side of the shaft, a double-wedge separator secured to the car, one wedge portion located on each side of the nut, said wedges adapted to separate the bracing-levers on approach of the nut, substantially as set forth.

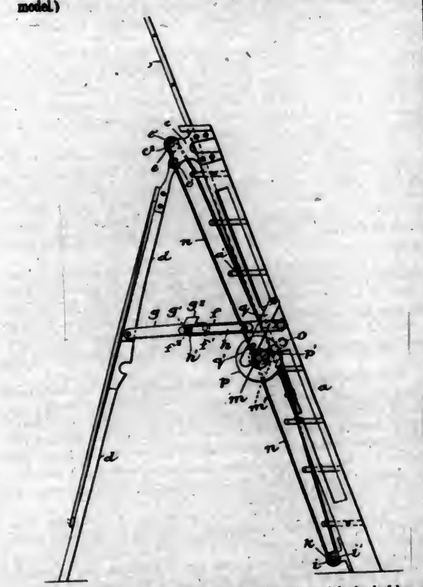
6. In elevating mechanism, the combination of an elevator-car, an elevator-shaft, a screw extending longitudinally in said shaft, a nut secured to said car and meshing with said screw, means for rotating said nut, pairs of bracing-levers, each provided with a roller, located at intervals along said screw and journaled to the side of the shaft, a double-wedge separator secured to said car, one wedge portion located on each side of the nut, said wedges adapted to engage said rollers and separate said levers on approach of the nut, substantially as set forth.

605,468. BONDING AND TYING. JOHN BENNETT, Paris, Me. Filed Dec. 20, 1897. Serial No. 662,602. (No model.)

Claim.—1. A bond for joining and bracing bodies, consisting of a two-part bonding-bar, one cast over and inclosing the other bar

and both bars engaging invisible excavations in the joining ends of the bodies.

2. A bond for joining and bracing bodies having excavations in their joining-surfaces, consisting of a double-ended solid tie-bar entering said excavations, and a fastening part cast over and enveloping the entire body of said solid bar within said excavations and crossing the joining-surfaces, the enveloping bond forming a tubular engaging-body within the joined parts.



3. For joining and bracing bodies having excavations, in their joining-surfaces, a solid bar entering alike said excavations and a bond cast of tubular form crossing the joining-surfaces as a fastening for the solid bar to the surrounding walls of the excavations in the way stated.

4. For joining and bracing bodies having excavations in their joining-surfaces and grooves or channels opening into said excavations and a filling-duct opening at the surface of the joined parts, a solid bar entering alike said excavations, and a bond cast of tubular form crossing the joining-surfaces for fastening the solid bar to the walls of the excavations and forming circumferential projections or arms upon said cast bond at the joining of the bonded bodies.

5. For joining and bracing bodies having excavations in their joining-surfaces, a tubular fastening-bond cast over a strengthening-blood within and crossing the joining-surfaces.

6. A bond for joining and bracing bodies consisting of a solid bar and a bar formed around it having circumferential arms, both bars and arms engaging the joined parts.

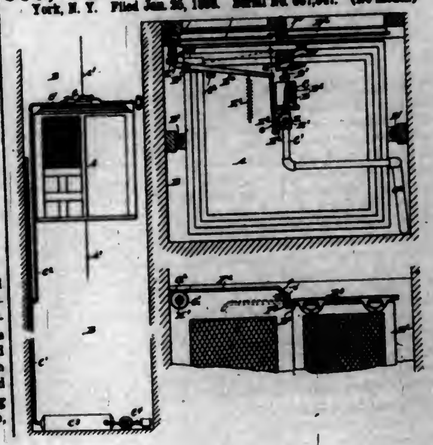
605,469. EXTENSION-LADDER. PHILIP BOURNE, Brooklyn, N. Y., assignor of one-half to Charles L. Dubar and Eugene F. Vacheron, of New York. Filed Aug. 18, 1897. Serial No. 648,677. (No model.)

Claim.—1. In a step-ladder, the combination with the ladder and support, of two arms pivoted respectively to the ladder and the support, and the end of one of said arms pivoted to the other arm intermediate the extremities thereof, there being openings in said arms adapted to correspond with each other when the arms are in extended position, a spring-clip carried by one of said arms and provided with a lug adapted to enter both openings when the same correspond, and an angular projection upon the other arm adapted to guide said lug into the opening upon the arm provided with the angular projection, substantially as described.

2. In a step-ladder, the combination of an extension-ladder adapted to slide therein, a windlass mounted upon said step-ladder, pulleys at the upper and lower ends of the step-ladder, and a cord wound on said windlass and having its ends leading respectively over said pulleys and fastened to the lower end of the extension-ladder, substantially as described.

3. In a step-ladder, the combination of an extension-ladder adapted to slide therein, a windlass mounted upon said step-ladder, pulleys at the upper and lower ends of the step-ladder, a cord wound on said windlass and having its ends leading respectively over said pulleys and fastened to the lower end of the extension-ladder, a face-plate fixed to one end of the windlass-shaft and provided with an opening therein, and a spring-clip fixed to the ladder and having a lug adapted to engage with said opening, substantially as described.

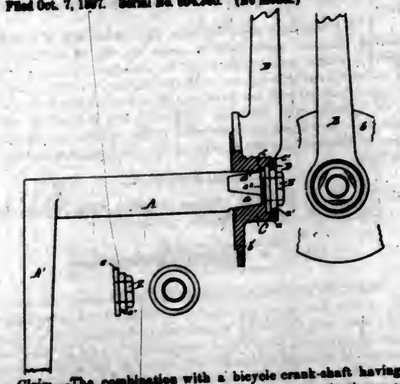
4. In a step-ladder, the combination of an extension-ladder adapted to slide therein, a windlass mounted upon said step-ladder, pulleys at the upper and lower ends of the step-ladder, a cord wound on said windlass and having its ends leading respectively over said pulleys and fastened to the lower end of the extension-ladder, a face-plate fixed to one end of the windlass-shaft and provided with an opening therein, a spring-clip fixed to the step ladder and having a lug adapted to engage with said opening, a support pivoted to said step-ladder, two arms pivoted respectively to the step-ladder and the support and the end of one of said arms pivoted to the other arm intermediate the extremities thereof, there being openings in said arms adapted to correspond with each other when the arms are in extended position, a spring-clip carried by one of said arms and provided with a lug adapted to enter both openings when the same correspond, and an angular projection upon the other arm adapted to guide said lug into the opening upon the arm provided with the angular projection, substantially as described.



605,470. FASTENING DEVICE FOR TUBS, BOXES, &c. FREDERICK T. BRADLEE, Boston, Mass., assignor of two-thirds to Alonzo G. Bradish, Medford, and C. Fred Fellows, Malden, Mass. Filed Aug. 11, 1897. Serial No. 647,334. (No model.)

Claim.—1. The herein-described staple-like fastener, comprising two driving-legs, a connecting integral crown provided with serratices or depressions to form transverse lines of weakness and facilitate bending of the fastener, and a strengthening rib extended longitudinally of and integral with the crown, substantially as described.

2. The herein-described staple-like fastener comprising two driving-legs, and a connecting-crown provided with transverse indentations or depressions to form lines of weakness, said crown also having an integral longitudinal strengthening-rib crossing the indentations or depressions, substantially as and for the purpose described.



3. A staple-like fastener having two driving-legs, and a connecting-crown, the main portion of which has transverse lines of weakness in hardened and comparatively brittle metal, an integral longitudinal strengthening-rib of relatively soft and readily-bent metal crossing such lines of weakness, substantially as and for the purpose described.

605,471. ELEVATOR-CONTROLLER. FOUNTAIN S. BRAID, New York, N. Y. Filed Jan. 25, 1898. Serial No. 667,847. (No model.)

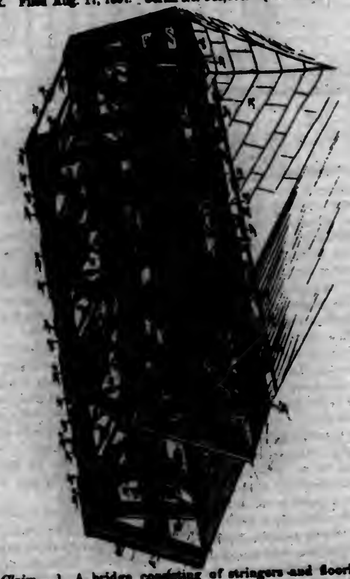
Claim.—In an elevator-controller of the character herein set forth, a clamp carried by the car and adapted to grasp and hold the operating-rope, a cylinder also carried by the car and receiving pressure, a piston mounted in said cylinder and moved by said pressure to actuate said clamp, and mechanism operated by the door in opening and closing, controlling the admission of pressure to said cylinder, so that the operating-rope will be clamped when said door is open and released when closed, all combined and arranged to serve substantially as and for the purposes herein specified.

605,472. BICYCLE-CRANK. JAMES G. BROWN, Reading, Pa., assignor to the Reading Cycle Manufacturing Company, same place. Filed Oct. 7, 1897. Serial No. 654,205. (No model.)

Claim.—The combination with a bicycle crank-shaft having a tapered body portion of angular cross-section and a projecting screw-threaded portion, of an engaging crank having a hub adapted to engage said tapered body, a counterbore in said hub forming a shoulder *c*, and screw-threaded at *c'*; a nut having a flange seating against said shoulder, and a cylindrical body portion adjacent to the flange, and a collar loose upon said cylindrical body of the nut and having its periphery screw-threaded to engage the threaded counterbore of the hub; substantially as set forth.

605,473. PIE-RACK. JOSEPH M. BROWN, Cleveland, Ohio. Filed July 26, 1897. Serial No. 645,891. (No model.)

Claim.—1. A pie-rack composed of the following: a semicylindrical upright stationary screen or cage having a horizontally-arranged top and horizontally-arranged base; a semicylindrical revolving screen having a top arranged horizontally above the top of the stationary screen, and a base arranged horizontally below the base of the stationary screen, and the wire fabric arranged concentrically of the said revolving screen's axis and outside of the wire fabric of the stationary screen, and the pivotal centers or bearings for the revolving screen projecting from the top and base of the stationary screen into the top and base, respectively, of the revolving screen, substantially as and for the purpose set forth.



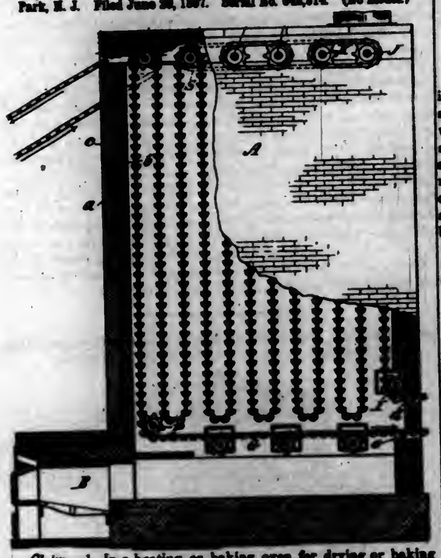
2. A pie-rack consisting of the following: a stationary screen or cage comprising the base b, the top b', the wire fabric b^2 and the two upright slats or bars b^3 b^3, shelf-forming frames suitably arranged within said screen, and one of said frames having two members that extend through the base and top, respectively, and form bearings, and the revolving screen comprising the base C', the top C^2, wire fabric C^3 and the slats or bars C^4 C^4, and having its top and base mounted upon the aforesaid bearings, all arranged and operating substantially as shown, for the purpose specified.

3. A pie-rack comprising a stationary screen having a top and base that are composed of wood, and have V-shaped notches centrally of their edges at the screen's open side; metallic pieces fixed within said notches and provided with angular vertical holes; shelf-forming frames arranged within the said screen, and one of said frames having lugs that engage and extend through the aforesaid holes and terminate in coincident bearings beyond the said holes, and the revolving screen mounted upon the said bearings, substantially as and for the purpose set forth.

4. A pie-rack comprising a stationary screen having a top and base that are composed of wood, and having V-shaped notches centrally of their edges at the screen's open side; metallic pieces fixed within said notches and provided with angular vertical holes; shelf-forming frames arranged within the said screen, and one of said frames having lugs that engage and extend through the aforesaid holes and terminate in coincident bearings beyond the said holes; the revolving screen large enough to embrace the stationary screen and having a top and a base that are composed of wood, and have V-shaped notches centrally of their edges at the screen's open side, and metallic pieces fixed within the said last-mentioned notches and having holes engaged by the aforesaid bearings, substantially as shown, for the purpose specified.

5. The combination with the stationary screen having a horizontally-arranged top, a horizontally-arranged base and wire fabric extending between and secured to said base and top; and the revolving screen having a base arranged below the base of the stationary screen, a top arranged above the top of the stationary screen, and the wire fabric stretched between and secured to the said top and base; of metallic pieces fixed within the tops and bases of said screens centrally of the latter's open sides; upright metallic frames secured to the top and base of the stationary screen, and one of said frames being provided, at its upper end, with an upwardly-projecting lug that extends through and is stationary with the metallic piece set within the top of the stationary screen, and has a seat formed at its upper end and instrumental in supporting the revolving screen, and has the upper pivotal center or bearing of the revolving screen formed thereon; a lug or member rigid with and depending from the lower end of one of the shelf-forming frames and extending through and stationary with the metallic piece fixed within the base of the stationary screen, and having the lower pivotal center or bearing of the revolving screen formed thereon, and the legs-forming frame attached to the said lower bearing, substantially as shown, for the purpose specified.

605,474. BRIDGE CONSTRUCTION. JAMES A. DAVIDSON, Millsap, Tex. Filed Aug. 17, 1897. Serial No. 648,626. (No model.)



Claim.—1. A bridge consisting of stringers and flooring supported between double-walled trusses composed of longitudinal rails

secured in duplicate and parallel alinement by means of angular supports and inner plates, and held together by means of outer plates and bolts passing therethrough, and supplemental vertical, longitudinal and diagonal brace-rods adapted to be made taut by means of turnbuckles, all substantially as herein shown and set forth.

2. The combination in a double-walled truss-bridge, of rail portions supported in duplicate and parallel to each other by means of inner and outer plates and angular supporting portions, other plates adapted to secure the top and bottom rails to said supporting angular portion, and a system of braces consisting of rods projected transversely, vertically and diagonally, said rods being provided with turnbuckles for tightening the same, all substantially as herein shown and set forth.

3. The combination in a double-walled truss-bridge, of stringers and flooring supported between said trusses, the latter consisting of longitudinal rail-plates A in duplicate supported by angular portions B secured thereon separated from each other by plates C centrally and through plates E at the top and bottom portions of the truss, also separated laterally by means of spacers G, and connected and braced laterally, diagonally and longitudinally by means of brace-rods K, K' and M, said rods being provided with turnbuckles L for making taut the same, the whole, constructed, arranged and adapted for operation substantially as herein shown and set forth.

605,475. DRYING APPARATUS. THOMAS A. EDISON, Llewellyn Park, N. J. Filed June 30, 1897. Serial No. 642,814. (No model.)

Claim.—1. In a heating or baking oven for drying or baking pulverized ore and similar material in bulk, the combination of a vertically-disposed heating-chamber, means for heating the same, a series of shafts passing through the interior of the chamber near the upper end thereof, a continuous conveying-chain near each side of the chamber extending over said shafts and hanging in free loops, a series of swinging buckets carried by said chains, and means for driving the chains at an approximately constant speed throughout their lengths, substantially as and for the purposes set forth.

2. In a heating or baking oven for drying or baking pulverized ore and similar material in bulk, the combination of a vertically-disposed heating-chamber, a furnace adjacent to said chamber, the products of combustion of which are directed through the chamber, shafts mounted in the heating-chamber near its upper end and in the same horizontal plane, a continuous conveying-chain near each side of the chamber extending over said shafts and hanging in free loops, a series of swinging buckets carried by said chains, and means for driving the chains at an approximately constant speed throughout their lengths, substantially as and for the purposes set forth.

3. In a heating and baking oven, the combination of a vertical heating-chamber, shafts passing through the interior of the chamber, sprocket-wheels on said shafts within the chamber, chains hanging in free loops from said sprocket-wheels, a series of flights for carrying material attached to the chains, and means for driving the shafts positively at the same rate of speed, substantially as set forth.

4. In a heating and baking oven, the combination of a vertical heating-chamber, shafts passing through the interior of the chamber, sprocket-wheels on said shafts within the chamber, endless chains hanging in free loops from said sprocket-wheels, a series of swinging flights for carrying material attached to the chains, means for driving one of the shafts outside of the chamber, and sprocket-wheels and chains connecting the several shafts outside the chamber arranged alternately on opposite sides of the chamber, whereby all the shafts will be driven at the same rate of speed, substantially as set forth.

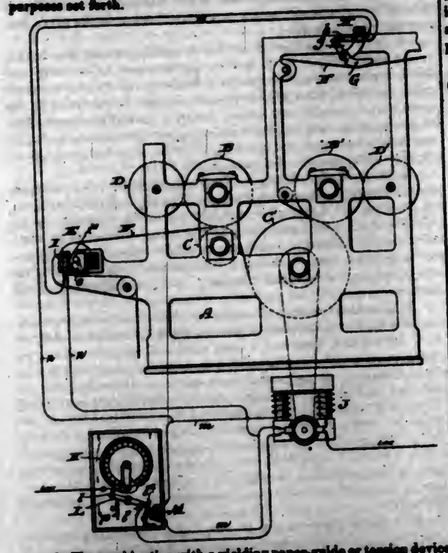
5. In a heating and baking oven, the combination of a vertical heating-chamber, shafts passing across the top of said chamber, sprocket-wheels on said shafts within the chamber, chains hanging in free loops from said sprocket-wheels, and a series of swinging perforated U-shaped buckets carried by said chains, substantially as set forth.

6. In a heating and baking oven, the combination of a vertical heating-chamber, shafts passing across the top of said chamber, sprocket-wheels on said shafts within the chamber, a conveyer formed of endless chains passing over said sprocket-wheels with a series of swinging buckets between them, said conveyer hanging in free loops in the chamber, and means for supporting and conducting part of such conveyer without the oven, whereby the material may be placed upon or removed from the buckets of the conveyers, substantially as set forth.

605,476. SYRINGE. EUGÈNE FOURNIER, Paris, France. Filed May 13, 1897. Serial No. 636,965. (No model.)

Claim.—In a hypodermic syringe, the combination with the cylinder or tube having one end shaped as described and being flanged at the other end to provide finger-rests, of a tubular rod arranged within the cylinder and provided with a recess toward its inner end, a second rod arranged within the first, a head on the inner end of the second rod a projection also on the latter rod engaging within the recess in the tubular rod, an elastic washer on the said second rod confined between the head and the inner end of the tubular rod, and an adjusting-nut screwed upon the outer end of the second rod and bearing against the outer end of the tubular rod.

605,477. BICYCLE-SUPPORT. JAMES F. PURLEY, North Sydney, and ROBERTS FORSYTH, Willoughby, New South Wales. Filed Nov. 26, 1897. Serial No. 660,040. (No model.)



Claim.—1. In combination with a bicycle, sleeves secured thereto, the central leg or rod guided vertically in said sleeves, the spring-pressed yoke vertically movable on said rod and the side legs or rods having their upper ends pivotally connected with the yoke and their lower ends linked to the central rod, substantially as described.

2. A bicycle-support with a vertical rod or center leg, passing through vertically-secured sleeves and a head-piece H, having hinged thereto the outer legs K, K, connected at or near their lower ends with the vertical rod or center leg, the downward movement of same being regulated by a spiral spring placed around a part of the vertical rod or center leg, between one of the vertical sleeves and the head-piece, the said vertical rod or center leg being governed in its downward passage by a collar placed above the head-piece, substantially as herein described, explained, and illustrated in the drawings.

3. In combination with a bicycle a pair of sleeves secured thereto, one above the other, a center leg vertically guided in said sleeves, a spring-pressed yoke movably carried on said leg, the side legs hinged to said yoke at their upper ends, links connecting said side legs with the center leg at the lower end, and the folding or jointed backstay P having a hinge connection with the central leg and with the bicycle-frame, substantially as described.

605,478. AUTOMATIC STOP MECHANISM FOR PRINTING-PRESSES. GEORGE GIBB, Milwaukee, Wis., and IRVING STONE, Chicago, Ill., assignors to the Gibbs Electric Company, Milwaukee, Wis. Filed June 12, 1897. Serial No. 640,494. (No model.)

Claim.—1. The combination with a machine for operating upon material fed thereto and an electric motor for driving said machine, of a movable device arranged to bear or press against the material upon which the machine operates, a switch in the motor-circuit having a tendency to open, a detent for holding said switch normally closed, a magnet arranged when energized to disengage said detent and having its winding in a shunt of the motor-circuit, and a circuit-breaker normally short-circuiting said shunt around the magnet and arranged to be opened by said movable bearing device whenever the material on which it bears is withdrawn, substantially as and for the purposes set forth.

2. The combination with a yielding paper-guide or tension device of a web-printing press and an electric motor for driving the press, of a switch in the motor-circuit having a constant tendency to open, a detent for holding said switch normally closed, a magnet for disengaging said detent and releasing said switch, having its winding in a shunt of the motor-circuit, a short circuit tapping said shunt on opposite sides of said magnet, and a circuit-breaker in said short circuit arranged to be opened by said tension device or guide whenever it is released by the breaking or tearing of the paper, substantially as and for the purposes set forth.

3. The combination with a machine adapted to operate upon a continuous web or strip of material, and a motor for driving said machine, of a motor-stopping device, a magnet for operating said stopping device, having its winding connected with a source of current, a circuit-controller normally closed and short-circuiting said magnet, and a movable device normally supported by said web or strip and arranged whenever the web or strip is severed or slackened to open said circuit-controller and thus cause the magnet to be energized, substantially as and for the purposes set forth.

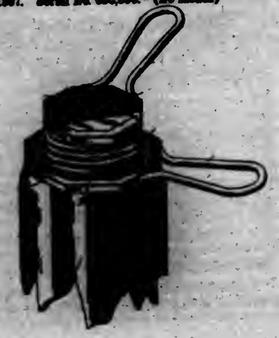
605,479. WARP STOP-MOTION FOR NARROW-WARE LOOMS. JOSIAH HARRIMAN, Lowell, Mass. Filed Feb. 7, 1896. Serial No. 578,236. (No model.)

Claim.—In a loom the combination of a conducting-plate, a conducting-guide, conducting drop-wires, arranged in said guide and each adapted to be supported normally by a warp-thread out of contact with said plate, an electric circuit including said guide and plate, an alarm device arranged in said circuit and operated by the closing of the same, when a drop-wire falls, into contact with said plate on the breaking or slacking of the thread which normally supports said drop-wire, said plate being of elastic material and inclined to the path of a falling drop-wire in order that the fall of said wire may scrape said plate and make a perfect contact between said wire and plate as and for the purpose specified.

605,480. HOSE-SUPPORTER. DORA HARRISON, Lansing, Mich., assignor to the Harrison Manufacturing Company, Grand Rapids, Mich. Filed Apr. 22, 1897. Serial No. 633,399. (No model.)

Claim.—In a hose-supporter, the combination with an attaching device, of a link pivoted thereto, a ball-supporting plate having an eye pivotally receiving the link, a pneumatic ball comprising a base, a shank, and a head, the base being laid on the ball-supporting plate and being held by flanges formed on the latter, the said ball-supporting plate having an orifice registering with the cavity in the ball, and a loop hung from said attaching device and capable of embracing the pneumatic ball.

605,481. BOTTLE-STOPPER. PARLEE G. HERSEY, Bayota, N. J. Filed Sept. 10, 1896. Serial No. 605,397. (No model.)

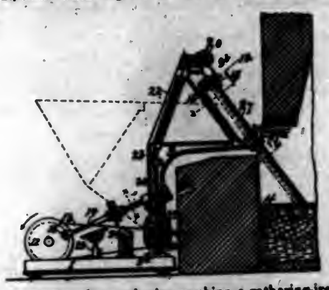


Claim.—1. As an article of manufacture, a bottle or like receptacle for liquids, closed at its mouth by an imperforate elastic cap, provided with one or more longitudinal indentations, said indentations serving to indicate where the cap is to be slitted to form a longitudinal automatically-closing vent therefor, substantially as shown and described.

2. The combination with a bottle or other liquid-holder, of an elastic cap fitted over the mouth of the bottle and closed at its outer end, and formed near its closed outer end with one or more longitudinal indentations, said indentations serving to indicate where the cap is to be slitted to form longitudinal automatically-closing vents for the discharge of the liquid, and an annular indentation near the lower end of said elastic cap to receive a retaining-wire.

3. The combination with a bottle or liquid-holder, of an imperforate elastic cap, provided with one or more longitudinal indentations, said indentations serving to indicate where the cap is to be slitted to form a longitudinal automatically-closing vent therefor, said cap being also provided with a contracted or flattened portion to form the edges S, substantially as shown and described.

4. As an article of manufacture, a bottle or like receptacle for liquids, closed at its mouth by an imperforate elastic cap, provided with a top of inverted-cone shape, said cone-shape portion having longitudinal indentations serving to indicate where the cap is to be slitted to form longitudinal automatically-closing vents therefor, substantially as shown and described.



605,482. JAR, TOP, AND WRENCH FOR PRESERVING FRUITS OR THE LIKE. SAMUEL P. JAGGARD, Blackwood, N. J. Filed Sept. 4, 1897. Serial No. 650,898. (No model.)

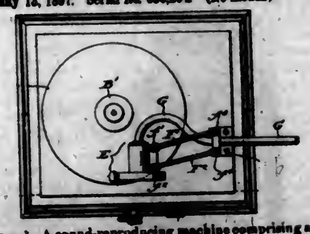
Claim.—1. A jar comprising a body, a polygonal ring of less diameter than the body formed at the top thereof, a threaded neck of still smaller diameter formed on said body and a slanting surface formed between said neck and said ring on which a washer is adapted to rest, a cover for said jar threaded to fit the threaded neck, said cover having a top polygonal in shape and of less diameter than the body thereof producing a shoulder, as and for the purpose described.

2. The herein-described combination of a jar having a threaded neck and cover threaded to fit said neck, said jar and cover having surfaces formed thereon, adapted to be engaged by wrenches, said surfaces being formed in such a manner as to prevent the wrenches from slipping downward, substantially as described.

605,483. GLASS-GATHERING MACHINE. EDWIN H. JEWETT, Toledo, Ohio. Filed Aug. 13, 1897. Serial No. 648,117. (No model.)

Claim.—1. In a glass-gathering machine, a gathering-iron holder, means to move the holder toward and from the glass, and means to move the holder farther forward at each successive forward movement thereof.

2. In a glass-gathering machine, a rotary gathering-iron holder, means to rotate the holder, means to move the holder forward and back, and adjustable means independent of the mechanism for moving the holder forward and back, to regulate the period at which the holder will begin to move back, substantially as described.



3. In a glass-gathering machine, a frame pivotally supported, a revoluble gathering-iron holder thereon, means to revolve the holder, a crank-wheel, a rod intermediate the said wheel and frame, screw connections between said rod and frame, and adjustable means for actuating the said screw connections.

4. In a glass-gathering machine, a pivoted frame, a gathering-iron holder thereon, a crank-wheel, a nut upon said frame, a hollow screw within said nut, a connecting-rod journaled on said crank-wheel and sliding within said hollow screw, a stop limiting the throw of said frame, and a spring adapted to press said holder normally away from the fire-pot.

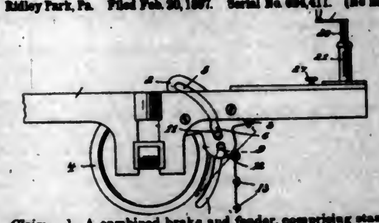
5. In a glass-gathering machine, a gathering-iron holder, means to rotate the same, means to move the holder forward and back, a compound cam having segmental extensible faces, adjustable in the arc of a circle, and connections intermediate said cam and said holder whereby the period of the dip of the gathering-iron may be adjustably controlled.

6. In a glass-gathering machine, a swinging frame, two gathering-iron socket-pieces journaled side by side on said frame, in combination with suitable driving mechanism for swinging said frame backward and forward and for rotating said socket-pieces, substantially as and for the purpose specified.

605,484. SOUND-REPRODUCING MACHINE. JOSEPH W. JOHNS, Philadelphia, Pa., assignor to himself and Joseph A. Vincent, same place. Filed May 13, 1897. Serial No. 636,394. (No model.)

Claim.—1. A sound-reproducing machine comprising a rotatable table, a record thereon, spring means for rotating said table, a sound-box provided with a diaphragm and stylus, a bracket secured to the framework of the machine and short parallel rods pivoted to said bracket and to the sound-box, substantially as specified.

2. A sound-reproducing machine comprising a rotatable table, a record-disk detachably secured thereto, spring means for rotating said table, a sound-box provided with a diaphragm, and stylus, the latter having a bar interposed between the diaphragm and sound-box provided with an annular cushion supported by the rim of the sound-box, and cushions at the point where the bar is united to the diaphragm, a bracket connected to the framework of the machine, parallel rods pivoted to said bracket and to a projecting ledge upon the sound-box, substantially as specified.

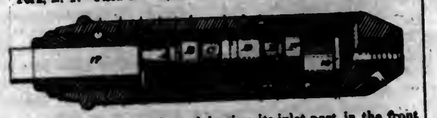


3. A sound-reproducing machine comprising a rotatable table, a record detachably secured thereto, spring means for rotating said table, a sound-box provided with a diaphragm and stylus operated upon by the record, a flexible bracket secured to the frame of the machine, two parallel rods each of which is pivoted at opposite ends to the sound-box and flexible bracket, a governor upon the operating mechanism and means independent of the action of the governor for regulating the speed of the mechanism.

4. A sound-reproducing machine comprising a rotatable table mounted upon a vertical shaft, a record-disk detachably secured thereto, a driving-disk feathered to said shaft and held in frictional contact with the driving mechanism by a spring, spring mechanism for operating the driving-disk, a sound-box provided with a diaphragm and stylus operated upon by the record and parallel rods pivoted to the sound-box and to a bracket mounted upon the framework of the machine.

5. A sound-reproducing machine comprising a rotatable table, mounted upon a vertical shaft, a record-disk detachably secured thereto, a driving-disk feathered to said shaft and operated upon by a spring, a pulley for rotating said disk mounted upon a horizontal shaft, rotated by spring mechanism, a governor driven by a flexible belt from said shaft, a disk upon one of the movable parts of said governor, an adjusting-screw having upon one end a disk and pad which is capable of being brought into and out of contact with the disk of the governor for regulating the speed of the operating mechanism, a sound-box provided with a diaphragm and stylus, operated upon by the record, and parallel rods for guiding the sound-box, pivoted to the latter and to a bracket mounted upon the framework of the machine.

6. A sound-box for a sound recording or reproducing machine, consisting of a flexible stylus-lever inclosed within the sound-box and fulcrumed to the wall of the same by an annular ring of elastic material, one end of said stylus being connected to the diaphragm through the medium of a screw and cushion, and the opposite end being provided with a detachable stylus.



605,485. BRAKE FOR TROLLEY-CARS. ALONZO H. KLINGLER, Ridley Park, Pa. Filed Feb. 20, 1897. Serial No. 624,411. (No model.)

Claim.—1. A combined brake and fender, comprising standards adapted to be secured to a car-truck frame and having slots of different radii as to the upper and lower portions thereof, brake-shoes provided with cross-bars to form a fender and said shoes having grooves or recesses in the walls of the same of different radii as to the upper and lower portions thereof, pins carried by said shoes and standards for engaging and moving in the slots and grooves respectively of said standards and shoes and means for actuating said brake-shoes in the slots of said standards, substantially as and for the purposes described.

2. A combined brake and fender, comprising standards adapted to be secured to a car-truck frame and provided with irregular slots, pins carried by said slotted standards, brake-shoes in the rear grooved out to contour with the car-wheels and in front provided with transverse means to form a fender, said shoes in the outer surfaces provided with irregular grooves or recesses adapted to be engaged by the pins of said standards, pins carried by said shoes and adapted to engage the irregular slots of said standards, whereby when said shoes are elevated said pins working in said irregular slots will cause the brake and fender to clear the car-wheels and means for actuating and controlling the positions of said fender and brake, substantially as and for the purposes described.

605,486. PNEUMATIC HAMMER. HERMAN C. KOTTER, New York, N. Y. Filed Oct. 22, 1897. Serial No. 656,023. (No model.)

Claim.—1. A pneumatic tool having its inlet-port in the front end of the cylinder, substantially one-quarter the size of the inlet-port on the back end of the cylinder, and the exhaust-port on the back end of said cylinder substantially one-quarter the size of the exhaust-port on the front or chisel end of the cylinder and all of said ports being controlled by the piston-hammer, whereby a comparatively slow backward movement and a very fast forward movement of the hammer are obtained.

2. In a pneumatic tool, a cylinder having a piston-hammer therein, the striking-face or nose of said hammer being of reduced diameter, a chisel-bushing in which said nose has an air-tight fit when the hammer is in its extreme forward or downward position, an exhaust-port controlled by said nose and leading to the atmosphere, said nose being adapted to be moved out of said bushing and other inlet and exhaust ports whereby movement is imparted to said hammer.

3. In a pneumatic tool, a cylinder, a piston-hammer contained therein, said hammer consisting of the grooved portions or necks C, E, the solid portions B, D, F of greater diameter and the nose A of reduced diameter, in combination with inlet and exhaust ports for admitting and exhausting the motive fluid to and from said cylinder, certain of said exhaust-ports being controlled by the nose of said hammer.

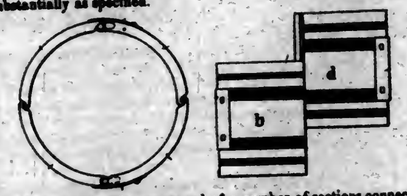
4. In a pneumatic tool, a cylinder and a main inlet-port having an enlarged supply-chamber communicating therewith, said chamber being located within the interior periphery of the cylinder, whereby no side pressure on the hammer exists, and other inlet and exhaust ports located within said cylinder, in combination with a hammer having a nose of reduced diameter, said nose being adapted to control certain of said exhaust-ports.

5. In a pneumatic tool, a cylinder having a chisel-bushing secured therein, a piston-hammer having a nose adapted to have an air-tight fit in said bushing when said hammer is in its extreme forward position, an exhaust-port passing through said bushing, and communicating with a main exhaust-passage in said cylinder, a main inlet and other inlet and exhaust ports for enabling motion to be imparted to said hammer.

6. A pneumatic tool, consisting of a cylinder having an inlet-port in the front end thereof, substantially one-quarter the size of the inlet-port on the back end thereof, and an exhaust-port at the back end thereof substantially one-quarter the size of the exhaust-port on the front or chisel end thereof, and a hammer in said cylinder provided with a reduced nose, the latter being adapted to control said exhaust-port at the chisel end of said cylinder.

7. In a pneumatic tool, a cylinder, a piston-hammer contained therein and provided with a nose of reduced diameter, exhaust-ports in said cylinder controlled by said nose and means for actuating said hammer.

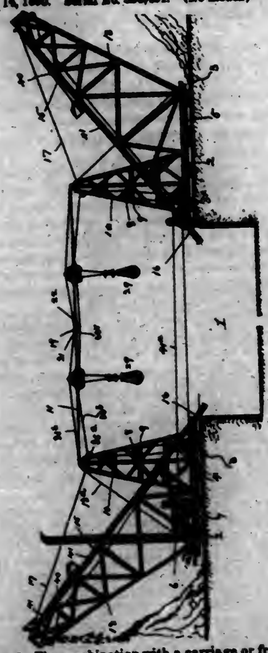
8. In a pneumatic tool a cylinder having a main inlet-port for the motive fluid, an enlarged supply-chamber communicating therewith, and located within the interior periphery of said cylinder, a piston-hammer movable in said cylinder and provided with a reduced nose, a chisel-bushing in said cylinder, which said nose is adapted to enter and an exhaust-port in said bushing controlled by said nose.



9. In a pneumatic tool, the combination of a cylinder having a chisel-bushing with an exhaust-port therein, a piston-hammer having a nose of reduced diameter controlling said port, and means for reciprocating said hammer.

10. In a pneumatic tool, the combination of a cylinder, a chisel-bushing, inserted therein, a plurality of exhaust-ports extending through said bushing and communicating with an annular passage, the latter leading to the atmosphere, a solid hammer in said cylinder provided with a nose of reduced diameter adapted to control said ports, and means for imparting to said hammer a comparatively slow backward movement and a very fast forward movement.

11. In a pneumatic tool, a cylinder, a piston-hammer adapted to reciprocate therein, said hammer being provided with a projecting striking-face, an exhaust-port in said cylinder controlled by said striking-face and other ports controlled by said hammer for actuating the latter.



605,487. COMBINED NAPKIN RING AND HOLDER. OTTMAR KNORR, Ohligs, Germany. Filed Feb. 5, 1898. Serial No. 669,230. (No model.)

Claim.—1. A napkin-ring composed of a number of jointed sections, rearwardly-extending noses on some of the sections, and springs adapted to engage said noses and secured to the adjoining sections, substantially as specified.

2. A napking-ring composed of a number of sections connected by hinges and by hook-shaped slip-joints, noses on some of the sections, and springs on the adjoining sections that are adapted to engage said noses, substantially as specified.

605,488. CABLEWAY SYSTEM AND APPARATUS FOR EXCAVATING AND CONVEYING. JAMES H. LAMBERTON, New York, N. Y. Filed Feb. 14, 1896. Serial No. 579,461. (No model.)

Claim.—1. The combination with a carriage or frame on a cableway, of an attached cable 35^b, operated by a driving wheel or drum to cause the carriage to travel back and forth, together with a second cable suspending a grapple or equivalent and guided through the carriage, said second cable being positively held at one end of the cableway-span, extending to the other end thereof and connected with operating means, substantially as set forth.

2. The carriage or frame on a cableway and adapted to travel back and forth thereon under the action of the driven cable 35^b, in combination with a pair of cables in operative relation with a grapple or equivalent for respectively closing and elevating the same, said pair of cables being positively held at one end of the span, and winding mechanism for either independently or conjointly operating the cables of said pair, substantially as set forth.

3. The combination with a suspended cableway, of a carriage or frame adapted to travel thereon, means for positively moving said carriage or frame back and forth, a grapple having sheaves connected with its head and blade-sections, and closing and elevating chains or cables passing around the respective sheaves and guided through the carriage, and positively held at one end, substantially as set forth.

4. A carriage or carrier comprising side frames, upper rollers and lower pairs of pulleys, a cableway upon which the upper rollers bear and travel, in combination with a double-chain digging or excavating device having the sheaves as described, and the closing and

raising cables of which, are guided through the longitudinal pairs of lower pulleys and positively secured at one end, together with means for operating said closing and raising cables, and the carriage-operating cable, substantially as set forth.

5. The combination with a cableway, of a carrier or frame adapted to travel thereon, a cable for moving the same and connected at one end thereto, passing around a fixed bearing-pulley, thence through a top guide of said carriage, next around a suitable operating-drum and finally again connected to the carriage; together with a second cable positively held beyond the carriage at one side thereof, passing through guides in said carriage and suspending and operating a grapple, substantially as set forth.

6. In operating apparatus for grapples, grabs, dredges and the like, the combination with an elevated cableway, of a carrier having rollers and pulleys as described, the former bearing on the cableway, a grapple or dredge having closing and raising sheaves and chains, closing and raising cables and a cable 35^b, for positively moving the carrier back and forth on the cableway, substantially as set forth.

7. In a system for operating a grapple upon a suspended cableway, the combination with the carrier having the pulleys, of the closing and elevating cables positively held at one end and guided through said pulleys and engaging the closing and elevating sheaves, the frames of which are connected by chains to the grapple, substantially as set forth.

8. In an excavating, hoisting and conveying apparatus, the combination of two movable-truck structures 4 and 5, cableway 11, load-carriage thereon, and a grapple, together with means controlled from one of the truck structures for shifting the load-carriage to, and closing or opening and cables or chains positively held at one end for elevating or lowering the grapple, at any point of the cableway, substantially as set forth.

9. In an excavating, hoisting and conveying apparatus, the combination of two movable truck structures 4, and 5, cableway 11, load-carriage thereon and its propelling-cable 35^b, means for actuating said cable, together with a grapple having closing and opening and elevating and lowering chains or cables positively held at one end to permit the charging and discharging and vertical movements of the grapple at any point along the cableway, said operating-cables being guided through the load-carriage to actuating mechanism on one of the truck structures, substantially as forth.

10. In an excavating, hoisting and conveying apparatus, the combination of two movable structures 4 and 5, cableway 11, load-carriage thereon and having upper rollers and lower pairs of pulleys, propelling-cable 35^b, means for actuating the same, together with a grapple or dredge having closing and raising sheaves and chains, and closing and opening and elevating and lowering chains or cables positively held at one end and passing around the respective sheaves, guided by the lower pairs of the carriage-pulleys, and led to one of the truck structures whereby the several movements of the grapples may be controlled from said structure to work the grapple at any point along the cableway, substantially as set forth.

11. In a system for operating a grapple upon a suspended cableway, the combination with the carrier having the supporting-rollers and lower pairs of guide-pulleys, of the cable for positively moving the carrier back and forth on the cableway, together with a grapple and cables for respectively closing and elevating the same, each of said cables passing over a front and rear guide-pulley and led oppositely along the cableway-span, substantially as set forth.

12. The combination with the carriage or frame on a cableway, of an attached cable 35^b, passing around a pulley secured to the cableway, and operated by a driving wheel or drum to cause the carriage to travel back and forth, together with a second cable suspending a grapple or equivalent and guided through the carriage, said second cable being positively held beyond and at one side of the carriage and extending to the other side thereof and connected with operating means, substantially as set forth.

13. In a system for operating grapples, upon a suspended cableway-span, the combination with a pair of carriers mounted on the same, a pair of pulleys secured intermediately thereof, a grapple suspended from each carrier by operating chains or cables positively held contiguous to said intermediate pulleys and guided in each carrier, and distinct carrier-moving cables connected to their respective carriers and passing around said pulleys, substantially as set forth.

14. In a system for operating grapples upon a suspended cableway-span, the combination with a pair of grapple-carriers and grapples, and their suspending and operating chains or cables positively held at one end and guided through their carriers, of carrier-operating cables and actuating mechanism adapted to move one carrier into, as the other is passed out of position, substantially as set forth.

15. In a suspended cableway system for operating grapples, the combination with a pair of truck structures between which the cableway is extended; of primary grapple-operating mechanism located on a truck structure and geared by a belt or cable transmission to similar mechanism on the second truck structure, together with a plurality of carriers on said cableway and from which the grapples are suspended, substantially as set forth.

16. The combination with a carrier on the suspended cableway, of a grapple, and a truck structure having a conveying way or chute for the material discharged from the grapple, and provided with carrier and grapple operating mechanism controlling cables adapted to raise and hold the grapple in relation to the carrier irrespective of the movement or position of the latter, and operate the grapple at any point of the cableway-span, substantially as set forth.

605,489. GRAPPLE, BUCKET, &c. JAMES H. LANCASTER, New York, N. Y. Filed Feb. 9, 1897. Serial No. 622,697. (No model.)

Claim.—1. In a bucket, grapple or similar construction, the combination with a head, of bucket-sections pivotally suspended therefrom by depending bars 10, movably connected to the outer upper edges of said bucket-sections, operating-levers secured to the bucket-shaft and connected by links to a sheave to be positively controlled by the rising or descending movement of the same, together with a chain connected with said head, passing around the sheave and led through an independent opening in the head, substantially as set forth.

2. In a bucket, grapple or similar construction the combination with a head having an opening 3, and parallel extensions terminating in ears, the extensions having square openings 6, a suspending-yoke rigidly engaged by a shaft 8 seated in said openings and an opening and closing chain connected to a pin bearing in said ears, passing around a sheave controlling the bucket-sections, and thence guided through the opening 3, substantially as set forth.

3. In a bucket, grapple or similar construction, the combination with a head, of bucket-sections, pivotally suspended therefrom by depending bars 10, movably connected to the outer upper edges of the bucket-sections, operating-levers positively secured to the bucket-shaft and attached to links, the upper ends of which are secured in the same horizontal plane as the journals of an operating-sheave to positively control the opening and closing of the bucket-sections, together with a chain connected to said head, passed around the sheave and led through the head, substantially as set forth.

4. In a grapple, bucket or similar construction, the combination with a head, of bucket-sections pivotally suspended therefrom by depending bars 10 movably connected to the outer edges of said bucket-sections, operating-levers secured to the bucket-shaft and connected by links to a sheave-containing case or housing for positively opening and closing the bucket-sections, together with a chain connected with said head, passed around the sheave and led through the head substantially as set forth.

5. In a grapple, bucket or similar construction, the combination with bucket-sections pivotally suspended from a head and having operating-levers connected by links to a sheave-carrying housing, provided with a lower projection or offset; of a chain connected to said head and passed around the sheave in the housing and led through the head, substantially as set forth.

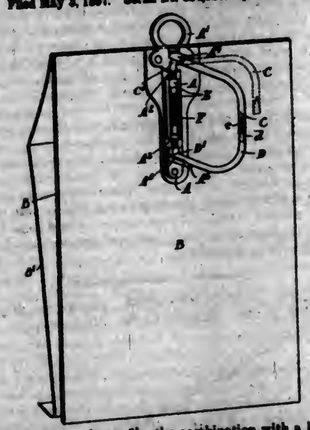
6. In a grapple, bucket or similar construction, the combination with a head in a single piece and having square openings in which bear the square portions of a shaft 8, from which the bucket-sections are suspended, of a lifting-yoke having square perforations engaged by the square portions of the shaft, together with levers 15, and connections operated by a closing and opening chain, substantially as set forth.

7. In a grapple, bucket or similar construction, the combination with a head in a single piece and having shaft 8, bad bolt 24 the former square bearing in openings 6, said head having an opening 3, bucket-sections pivotally suspended from the shaft 8, and having operating-levers connected by links to a housing carrying a sheave, a lifting yoke secured by shaft 8, and a closing and opening chain attached to the bolt 24, passed around the sheave and led upward through the opening 3, substantially as set forth.

8. In a grapple, bucket or similar construction, the combination with sections pivotally suspended from the head and having the operating-levers actuated by the raising and lowering chain, of a series of castings carrying the blade or digging sections and recessed as described, together with independent shoe or point sections, flush with the digging-sections and having a shoulder bearing against the castings, and a fish or tie plate 31, the whole being arranged and bolted, substantially as set forth.

605,490. NECK-YOKE. GEORGE A. LAWSON, Toronto, Canada, assignor of one-half to William Douglas, same place. Filed Sept. 7, 1897. Serial No. 650,941. (No model.)

Claim.—The combination with a neck-yoke, and a pole, of a ring arranged on the pole and provided with an upwardly-extending rearwardly-inclined stem formed integral with the ring, a solid ball arranged at the upper end of and formed integral with the stem and being of much greater diameter than the same, and a socket receiving the ball and provided at its back with a narrow slot receiving the stem and extending downward from the top of the socket to the center of the bottom portion thereof, said socket being provided at its top with a flange D' secured to the lower face of the neck-yoke, substantially as described.



605,491. QUININ DERIVATIVE AND PROCESS OF MAKING SAME. EMIL LANDSBERG, Stegitz, Germany. Filed Oct. 18, 1895. Serial No. 566,252. (Specimens.)

Claim.—1. The method of manufacturing derivates of quinin which consists in making a quinin solution and treating said solution with ozonized gas until precipitation will not be caused by an alkali.

2. The method of manufacturing derivates of quinin which consists in making a solution of quinin hydrochlorid in a mixture of water and alcohol and treating it with ozonized gas until precipitation will not be caused by an alkali.

3. The new derivate of quinin being an amorphous powder of yellowish color, very soluble in water, alcohol, ether, and benzene, having an acid reaction, and with the chemical formula $C_{19}H_{20}N_2O_3$.

605,492. LETTER-FILE. HERBERT P. LAVENDER, Walsall, England. Filed May 3, 1897. Serial No. 634,559. (No model.)

Claim.—1. In a letter-file, the combination with a base or support, and filing-arms pivotally connected with the support, of a spring carried by the support and compressed between the inner ends of the arms and tending to press said arms apart, and stops for limiting the movement of the arms away from each other.

2. In a letter-file, the combination with a base or support, of filing-arms having angularly-bent inner ends, a tube carried by the support into which tube the said bent ends of the arms project, a spring within the tube and bearing upon the bent ends of the arms and a stop on the support both above and below the tube against which the arms are pressed by the spring.

3. In a letter-file, the combination with a base or support, of a pair of grooved abutments A^a A^a, a tube E, filing-arms C, D, pivoted in the tube and movable in the direction of its axis, and means to keep the arms and abutments in engagement.

4. In a letter-file, the combination with a base or support, and a stop, of independent filing-arms arranged one above the other in substantially the same vertical plane and normally extending at substantially right angles to the support, one of said arms having a pivotal connection with the support and adapted to be moved first in a direction toward the other arm to free it from the stop and then to be swung upon its pivot laterally toward the face of the support, and a spring arranged to act upon the pivoted arm so as to tend to force the latter away from the other arm and to hold the pivoted arm in engagement with the stop when said pivoted arm is in its normal position over the other arm, substantially as described.

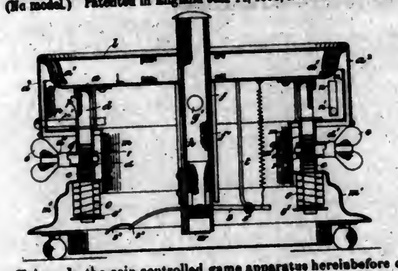
5. In a letter-file, the combination with a base or support, and stops, of filing-arms each pivotally connected with the support and adapted to be normally held by the stops in a position at right angles to the support, said arms being arranged one above the other in substantially the same vertical plane, and each arm being adapted to be moved toward the other arm to free it from its respective stop and to be swung upon its pivot laterally toward the face of the support, and a spring arranged to act upon both arms to tend to force the same in opposite directions and to cause them to engage their stops when in normal position one above the other, as described.

605,498. PERMUTATION-PADLOCK. MONROE LE VEE, New York, N. Y. Filed Aug. 3, 1897. Serial No. 646,983. (No model.)

Claim.—1. A permutation-padlock comprising a suitable casing, tumblers movably mounted within the casing, an adjustable back plate supported in the casing and formed with a gate or notch with which the tumblers register, and a bolt adapted to be engaged by the tumblers, as set forth.

2. A permutation-padlock comprising a suitable casing, suitably-controlled rotary tumblers supported in the casing and formed with gates or notches, a removable adjustable back plate formed with a gate or notch adapted to register with the gates of the tumblers, a bolt adapted to enter the gates of the back plate and tumblers, and a connection connecting the bolt with a part of the lock, as set forth.

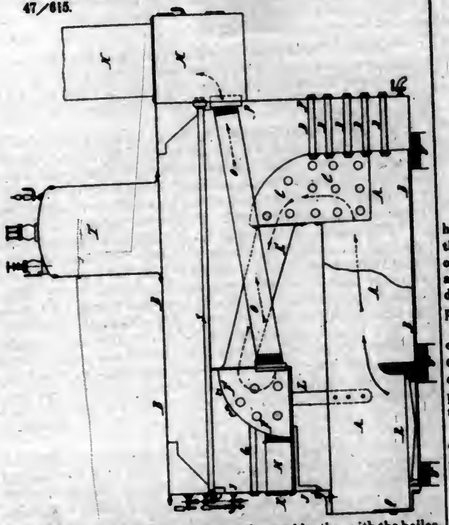
3. In a permutation-padlock, the combination with a casing, suitable tumblers mounted therein and held against removal, a removable adjustable back plate having a notch or gate, and a bolt adapted to enter said notch or gate and engage said tumblers and having a flange adapted to engage the back plate, the tumblers holding the bolt and the bolt holding the back plate in the casing, substantially as set forth.



4. A permutation-padlock comprising a suitable casing, suitable controlling-tumblers rotatably mounted within the casing and formed with suitable gates or notches, a removable adjustable back plate formed with a gate or notch, a bolt formed with a flanged head adapted to engage the back plate, a head upon the removable back plate, and a suitable connection connecting the bolt with the head on the back plate, substantially as set forth.

5. In a permutation-padlock, the combination of a suitable casing having a circular opening at back, a circular back plate adapted to engage therewith held from rotation only by close contact with its sides and capable of being set in an unlimited number of positions therein, tumblers held within the casing, the tumblers and back plate having corresponding gates or notches and a suitable bolt adapted to engage said gates or notches, substantially as set forth.

6. In a permutation-padlock, the combination of a casing having a dial-face, a plurality of arbors having individual hands adapted to move over said dial, rotatable tumblers fixed to the separate arbors, a circular back plate engaging the rear of the casing and capable of removal from and return to any position therein and held from turning only by close contact with its walls, the back plate and the tumblers having suitable corresponding gates or notches, and a bolt having a retaining chain or member and adapted to enter said gates or notches, substantially as set forth.

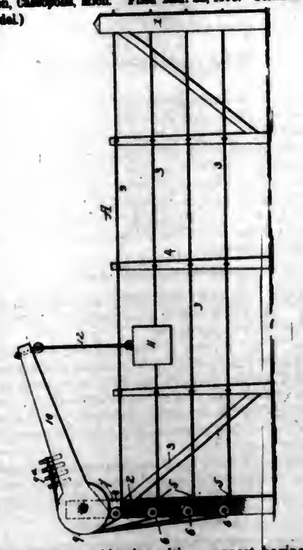


7. In a permutation-padlock, the combination of a suitable casing, tumblers therein, a back plate removable to enable the changing of the combination and having a flanged head adapted to engage the edge of the casing and prevent the back plate from bearing upon the tumblers, substantially as set forth.

605,494. COIN-CONTROLLED GAME APPARATUS. CHARLES M. LESLEY, London, England. Filed Mar. 18, 1897. Serial No. 627,695. (No model.) Patented in England Jan. 11, 1896, No. 730.

Claim.—In the coin-controlled game apparatus hereinbefore described, the table *a* having the holes *b*; the balls *b'*; the vertical racks *c*; the pinions *d* and levers or finger-grips *e*; the vertical tube *f*; the tubes *g* leading to the vertical tubes *f* and *h*; the central or inner raising and lowering tube *h* having the platform *x'* on which rests the coin *x*; the plunger *i* having the projection *z*; the coin-chute *k* attached at one end to a^2, and extending toward but not touching the platform *x'*; the glass cover *l*; the casing *m* provided with slots or apertures *n*; the stand *m'*; the guide-pins *n'*; the springs *o*; the brackets *p p'*; the tubes *q* and *r*; the tip s^2 and heel s^3 of the pivoted arm *s*; the bracket *t* and spring *u*; the box *v* and the stop *w*.

605,495. STEAM-GENERATOR. JEAN B. LOQUET and JEAN B. KESTELAIR, Antwerp, Belgium. Filed June 8, 1897. Serial No. 639,859. (No model.) Patented in Belgium May 28, 1896, No. 121,612; in England May 29, 1896, No. 11,733; in France June 16, 1896, No. 257,323; in Hungary Sept. 23, 1896, No. 7,504, and in Austria Feb. 27, 1897, No. 47/615.

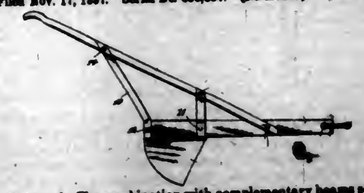


Claim.—1. In a steam-generator, the combination with the boiler-shell B bent inwardly at its lowest part to form the furnace-chamber A, of a combustion-chamber arranged toward the back of the boiler and at a distance from the walls thereof adapted to be surrounded by water, a combustion-chamber arranged toward the front of the boiler above the chamber A and in position to be surrounded by water, a tube connecting the said combustion-chambers, and a tube to conduct products of combustion from the front combustion-chamber.

2. In a steam-generator, the combination with the boiler-shell B bent inwardly at its lowest part to form the furnace-chamber A, of a combustion-chamber arranged toward the back of the boiler at a distance from the walls thereof adapted to be surrounded by water, a combustion-chamber arranged toward the front of the boiler above the chamber A in position to be surrounded by water, a tube connecting the two combustion-chambers, a smoke-box, and tubes leading from the front combustion-chamber to the smoke-box, the end of the tube leading into the front combustion-chamber from the rear combustion-chamber being at a higher level than the ends of the tubes leading to the smoke-box.

3. In a steam-generator, the combination with the furnace-chamber A, of a combustion-chamber C arranged toward the rear of the boiler in position to be surrounded by water, a combustion-chamber F arranged toward the front of the boiler above the chamber A, and adapted to be surrounded by water, a tube E connecting the chambers C and F and entering the latter chamber toward its upper end, and tubes O leading from the chamber F, at a point below the end of the tube E and crossing the latter as described.

605,496. WIRE-STRETCHER. BENJAMIN F. MANNING and JOHN MANNING, Elkhart, Ind.; said John Manning assignor to said Ebenezer F. Manning; said Ebenezer F. Manning assignor of one-half to R. C. Atkinson, Cassopolis, Mich. Filed Mar. 22, 1898. Serial No. 674,810. (No model.)



Claim.—1. The combination with a support having a series of holes and a pulley mounted in each hole, of a series of wires passing through said holes and over said pulleys, a drum mounted in the end of said support and having all of said wires connected therewith and adapted to wind thereon, and a weighted lever projecting from said drum whereby to maintain said wires taut during all changes of temperature to which they may be exposed, substantially as set forth.

2. In a fence, the combination with two end posts and wires secured to one of said posts and passing loosely through the other, a drum mounted in the top of said last-mentioned post and having all of said wires secured thereto and adapted to wind thereon, a lever projecting from said drum and over the fencing, and a weight attached to the free end of said lever, substantially as set forth.

3. In a wire-stretcher, the combination with a post, of a drum supported thereby, a series of keys carried by said drum for the reception of the fence-wires, and a weighted arm projecting from said drum, substantially as set forth.

605,497. ROOT OR SOD CUTTER. PINK MELTON, Winkler, Tex. Filed Nov. 17, 1897. Serial No. 658,837. (No model.)

Claim.—1. The combination with complementary beams secured side by side and having portions of their opposing sides cut away at their front ends, forming a space, of a clevis comprising a fibat bar having a series of openings, a middle bar having its rear end entering the said space, and side bars embracing the sides of the beams, and a bolt passing through transversely-alining openings in the side bars of the clevis and front ends of the beams and connecting all together, substantially as set forth.

2. The herein-described sod-cutter, comprising complementary beams having portions removed from their opposing faces at their front and rear ends, forming spaces, a cutter having its upper end inserted in the rear space, handles, front and rear braces secured at their upper ends to the handles, bolts securing the lower ends of the handles and braces to the beams and holding the latter together, the bolts passing through the lower ends of the braces serving as securing means for the cutter, a clevis comprising a middle bar having its rear end fitted into the front space formed between the beams, and side bars embracing the sides of the beams, and a bolt passing through transversely-alining openings in the beams and side bars of the clevis, substantially as described.

605,498. INCANDESCENT ELECTRIC LAMP. OTTO H. MICHAELSON, Charleston, W. Va. Filed July 17, 1897. Serial No. 644,953. (No model.)

Claim.—In an incandescent lamp, a base of insulating material having an annular groove in its outer end, a metal shell in which the base is secured, conductor-wires extended through the base-piece, a ring of insulating material in the shell, a metal ring on said insulating-ring and with which one of the wires connects, a metal ring in the insulating-ring and with which the other wire connects, a globe having a channel around the wall of its open end, and a packing-ring engaging said channel and in the groove of the base, substantially as specified.

605,499. AXLE-BEARING AND HUB. JACOB R. MIKESELL, Charlotte, Mich. Filed Jan. 21, 1898. Serial No. 667,462. (No model.)

Claim.—1. In a device of the class described, the combination of a reversible journal-box having a smooth bearing-opening and provided with an opening adapted to receive an end of an axle, said axle-opening being adapted to be arranged above or below the bearing-opening, a spindle arranged in the bearing-opening of the journal-box, and a hub secured to and rotating with the spindle, substantially as described.

2. In a device of the class described, the combination of a reversible journal-box provided with a smooth bearing-opening and having a threaded axle-opening and adapted to be reversed to bring either opening at the top, an axle having a threaded end fitting in the threaded opening of the journal-box, a spindle arranged in the bearing-opening, and a hub fixed to the spindle, substantially as described.

3. In a device of the class described, the combination of a journal-box having a bearing-opening and designed to be secured to an axle, a spindle arranged in the bearing-opening and provided at its inner end with an annular flange engaging the inner end of the journal-box, a cap or nut arranged on the inner end of the journal-box, a hub mounted on the spindle and arranged at the outer end of the journal-box, and a nut mounted on the outer end of the spindle and engaging the hub, substantially as described.

4. In a device of the class described, the combination of a journal-box having a bearing-opening, a spindle fitting in the bearing-opening and provided with a polygonal outer portion, a hub mounted on the polygonal portion of the spindle and provided with inner and outer tubular extensions, the inner tubular extension receiving the adjacent end of the journal-box, and a nut mounted on the outer end of the spindle and fitting within the outer tubular extension, substantially as described.

5. In a device of the class described, the combination of a journal-box, having a bearing-opening, a spindle fitting in the bearing-opening and provided with a polygonal outer portion, a cap or washer mounted on the inner end of the polygonal portion of the spindle and fitting over the adjacent end of the journal-box, and a hub arranged on the polygonal portion of the spindle and provided at its inner end with a tubular extension fitting over the cap or washer and the adjacent end of the journal-box, substantially as described.

6. In a device of the class described, the combination of a journal box, a spindle arranged in a bearing-opening of the same and provided with a polygonal outer portion and having its outer end threaded, a hub fitting on the polygonal portion of the spindle and provided with an outer tubular extension, and a nut arranged on the threaded portion of the spindle, fitting within the tubular extension of the hub and provided at its inner end with an annular flange, said nut being provided at its outer end with an annular flange L-shaped in cross-section and forming a cap for the outer end of the hub, substantially as described.

7. In a device of the class described, the combination with a spindle having a polygonal portion, of a hub having a polygonal opening to fit the spindle and comprising inner and outer sections provided at their inner faces with recesses, the recess of one section being larger than that of the other, and a central section provided with spoke-sockets and having one end fitting in the smaller recess, and provided at its other end with a flange fitting in the other recess, substantially as described.

8. In a device of the class described, a hub comprising inner and outer sections provided at their inner faces with recesses one of the recesses being smaller than the other, and a central section provided with spoke-sockets and having one end fitting in the smaller recess and provided at its other end with a flange arranged in the larger recess, substantially as described.

605,500. FILTER. DAVID B. MORRISON, Kansas City, Mo. Filed Sept. 21, 1897. Serial No. 652,468. (No model.)

Claim.—1. The combination with a cooler of a filter-frame supported on the bottom of the cooler, the top portion of the frame forming a water-tight joint with the side of the cooler, a filtering-wall supported by the filter-frame and the removable pan supported by the filter-frame and located adjacent the lower portion of the filter-wall.

2. The combination with a cooler of a filter-frame resting on the bottom of the cooler having its upper portion forming a water-tight joint with the sides of the cooler, a filtering-wall supported by the filter-frame, a convexed bottom for the filter-frame, a removable pan resting on the bottom and a drain-pipe leading through the various walls to the outside of the cooler.

3. The combination with a cooler of a filter-frame resting on the bottom of the cooler having its upper edge forming a water-tight joint with the sides of the cooler, a filtering-wall supported by the filtering-frame, a removable pan resting on the bottom of the filter-frame and a brush on the outside of the pan bearing against the filter-wall and adapted to clean the same when the pan is removed.

4. The combination with a cooler of a filter-frame resting on the bottom of the cooler having its upper edge forming a water-tight joint with the sides of the cooler, a suitable wall supported by the filter-frame, an air-pipe passing at its lower end through the filter-frame, and opening into the compartments above and below the filter-frame.

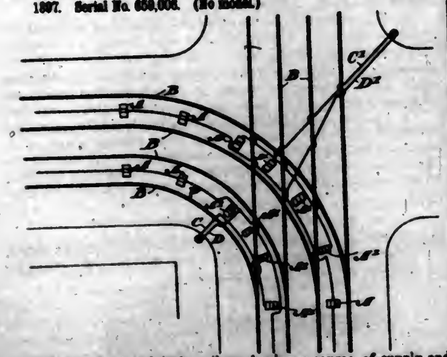
605,501. CUTTER FOR TRIMMING OR CUTTING BOILER-TUBES. JOSEPH G. MORRISS, Akron, Ohio. Filed May 26, 1897. Serial No. 638,507. (No model.)

Claim.—1. A wedge formed by inclined planes 14, the bottoms of inclined slots and portions between the slots fitted to slide within bearing in casing, the sides of the slots made to coincide with the

sides of the openings in the casing, substantially as set forth and for the purpose specified.

2. In an inside tube-cutting device the combination of an outside casing with openings for cutters; a sleeve fitted to revolve freely in the breech of the outer casing, this sleeve having an inside screw-thread through which passes the feed-screw and this feed-screw secured immovably to the core which carries the cutters, becoming the spindle by which these cutters are revolved, with the core having grooves with inclined bottoms formed in its mass and in the direction of its length that they may act as feed-wedges on the flanged cutter blocks which are fitted into and engage them and also hold the cutter-blocks so firmly that the core may carry them in their working as well as their feeding motion; together with a gage as described.

605,502. SAFETY-GATE. PETER MOTLEY, Philadelphia, Pa. Filed Oct. 8, 1897. Serial No. 654,581. (No model.)



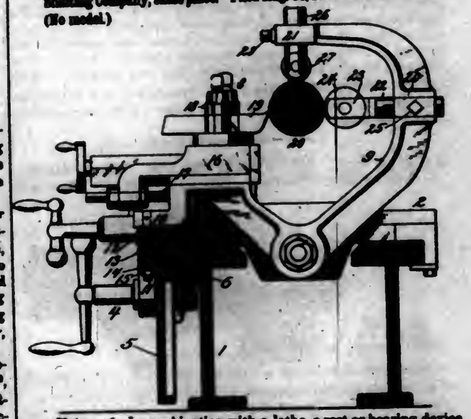
Claim.—1. In combination with the body of a gate of the character described, a sliding member consisting of the sliding bars fitting within the body of the gate, an upright connecting said bars, and bolts arranged on the body of the gate to engage said bars and hold the sliding member in adjustment, substantially as set forth.

2. In combination with the body of the gate of the character described, a sliding member consisting of the upright, bars projecting therefrom and telescopically arranged in the body of the gate, stops carried by the bars adapted to abut an upright of the body to limit the movement of the sliding member, bolts arranged on said body, a turnbuckle threaded on the inner ends of the bolts forcing the outer ends into engagement with the sliding bars, and a spring between the body of the gate and the upright of the sliding member, as and for the purpose set forth.

3. In combination with the body of a gate of the character described, a sliding member consisting of the bars E and an upright B^3, a spring arranged to force said member outward, sliding bars M attached to the body having pointed ends, and a turnbuckle for forcing said ends into the bars E, substantially as and for the purpose set forth.

605,503. ELECTRIC RAILWAY. ARTHUR J. MCKEAN, Lorain, Ohio, assignor to the Johnson Company, same place. Filed Nov. 15, 1897. Serial No. 658,008. (No model.)

Claim.—1. An electric railway having a source of supply and connections from the terminals thereof to conductors extending along the line of way, a series of contacts adapted to be placed in circuit with one of said conductors by the passing vehicle, in combination with a second series of contacts located adjacently to portions of the other of said conductors and having their circuit connections arranged so as to be unaffected by the passing vehicle.



2. An electric railway having a bared sectional conductor in series with one side of the circuit through a current-conveyer which is closed by the passing vehicle, and track-rails connected to the opposite side of the circuit, contacts placed adjacently to crossing track-rails and in circuit with the source of supply through a hand-operating device.

3. In an electric railway, the combination of the crossing track-rails, the contacts adjacent thereto, and the hand-operating switch in series with said contacts.

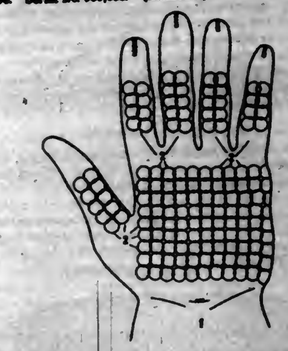
4. In an electric railway, the combination of disconnected contacts connected to the high-potential side of the circuit, main track-rails connected to the low-potential side of the same, track-rails crossing the main track-rails, and a hand-operating device interposed between the high-potential side of the circuit and such of the disconnected contacts as are adjacent to the crossing-rails.

5. In an electric railway, in combination, disconnected contacts connected to one side of the main circuit through suitable current-conveyers, main track-rails and crossing track-rails in connection with the opposite side of the main circuit and a hand-operating switch, normally held open by a suitable spring device, in circuit with such of the contacts as are adjacent to the said crossing track-rails.

605,504. TOOL HOLDER OR CARRIER. WALTER J. MUSGASTER, Cumberland, Md., assignor of one-half to the Cumberland Iron and Steel Shafting Company, same place. Filed Aug. 31, 1897. Serial No. 650,199. (No model.)

Claim.—1. In combination with a lathe, a rest or bearing device at one side of the spindle-axis; a tool at the opposite side thereof; a connection between the rest and the tool whereby they are caused to move in unison; and a spring arranged to hold the rest normally in contact with the work in the lathe.

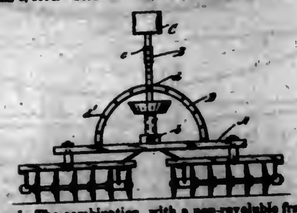
2. In combination with the tool-slide of a lathe, a tool-holder or carrier pivotally supported upon said slide, having a tool-support at one side of the axis of the lathe-spindles, and a roller at the opposite side of said axis adapted to bear upon the work carried by the lathe, the tool-support and the roller being held in fixed relation to each other while the device is in operation.



3. In combination with the tool-slide of a lathe, a tool holder or carrier pivotally supported upon said slide, having a tool-support at one side of the axis of the lathe-spindles, and rollers respectively at the opposite side of and above said axis adapted to bear upon the work carried by the lathe, the tool-holder and the rollers being clamped and held in fixed relation to each other preparatory to operation of the device.

4. In combination with the bed of a lathe, a tool-slide 2; means for moving said slide lengthwise of the lathe-bed; a frame or lever 9 pivotally supported upon said slide; a tool-support carried by said frame or lever; and bearing-rollers 24 and 27 also carried by said lever and serving to hold the tool against the work between it and the rollers.

5. In combination with lathe-bed 1, tool-slide 2; means for moving said slide along the bed; frame or lever 9 pivotally supported upon said bed; a spring serving to rock the frame or lever forward upon its pivot; a tool-holder carried by said frame; and cylindrical stems 22 and 26 adjustably mounted in the frame or lever and provided at their inner ends with rollers 24 and 27, substantially as described and shown.



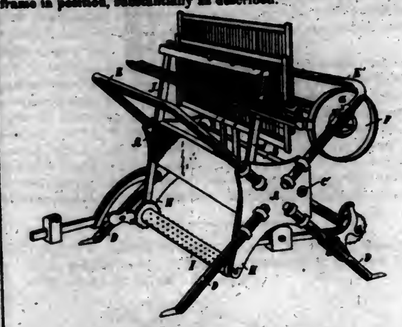
6. The herein-described tool holder or carrier consisting of a tool-slide 2; a lever or frame 9 pivotally supported thereon and provided with tail or extension 10; a rod or stem 11 extending from said tail through a flange or projection on the tool-slide and encircled by a spring 13; a nut or enlargement upon said stem beneath the spring; a tool-slide adjustable upon the lever; a cylindrical stem movable horizontally through the lever and carrying a bearing-roller 24 at the rear of the work; a cylindrical stem at the upper end of the roller carrying a bearing-roller 27 above the work; and binding-screws for securing said stems at the desired adjustments, substantially as set forth.

605,505. GLOVE. MAY MURRAY, Detroit, Mich. Filed Oct. 21, 1896. Serial No. 609,603. (No model.)

Claim.—As a new article of manufacture, a glove provided with guards upon its palm, inner thumb and finger portions, each guard consisting of rings interwoven with each other and means for securing said rings to said portions of the glove, substantially as described.

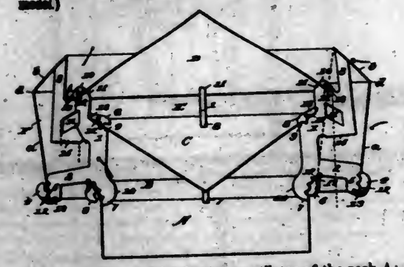
605,506. HARROW. MARK R. MCCLELLAND, Zanesville, Ohio. Filed Jan. 6, 1896. Serial No. 625,720. (No model.)

Claim.—1. The combination, with a non-revolvable frame which carries devices for operating on the ground, such as harrow disks or teeth; of a weighted lever pivoted to the middle part of the said frame, and means for supporting the said lever in a vertical position and at an angle, so as to equalize the down pressure at each side of the said frame, substantially as set forth.



2. The combination, with a non-revolvable frame which carries devices for operating on the ground, such as harrow disks or teeth; of a curved support secured to the said frame, a weighted lever formed in two parts which straddle the said support and which are pivoted to the middle part of the said frame, and means for connecting the said lever to the said support when said lever is in a vertical position and at an angle, so as to equalize the down pressure at each side of the said frame, substantially as set forth.

605,507. CARPET-LOOM FRAME. CHARLES H. HEWEBER, Davenport, Iowa. Filed Oct. 2, 1897. Serial No. 653,898. (No model.)



Claim.—1. In a loom, end plates provided with sockets, legs to fit in the sockets, said end plates being provided with downward extensions; combined with the standards, a shuttle-frame, and a tension-roller, the tension-roller being journaled in the extension upon the end plates, and made removable with the standards, substantially as described.

2. In a carpet-loom frame the castings or end plates provided with suitable sockets, combined with the back beam, and the adjustable angle-irons which are inserted into the ends of the beam and the sockets and the warp-roller supports secured to the beam, substantially as set forth.

3. In a carpet-loom frame, the end plates provided with suitable sockets to receive the legs, combined with the removable legs, the shuttle-carrying frame, and the tension-roller journaled in the shuttle-carrying frame; the end plates or castings being provided with slots or sockets which support the roller and the shuttle-carrying frame in position, substantially as described.

605,508. VENTILATOR AND VENTILATOR-BRACE. RICHARD M. PANCOAST, Camden, N. J., assignor to the Pancoast Ventilator Company, of New Jersey. Filed Aug. 31, 1896. Serial No. 604,371. (No model.)

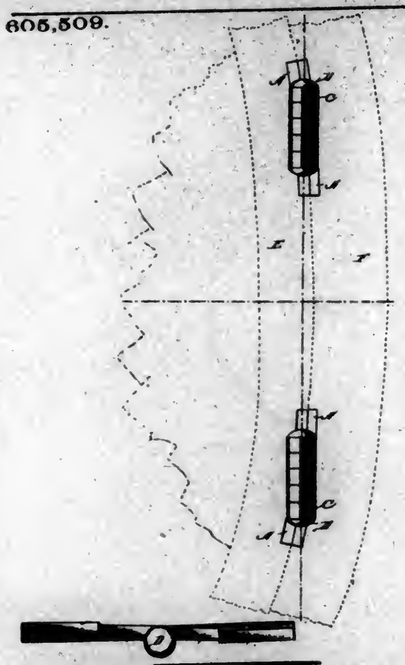
Claim.—1. The combination in a ventilator of the neck A; the cone C; the cone D made separate from cone C and with an open space E between; the deflector F; and means for securing the several enumerated parts in their proper relative positions, substantially as described.

2. An edgewise brace for holding in their proper relative positions the constituent elements of a ventilator, cowl, or cap, said brace being made of malleable metal and provided with jaws adapted to be closed down upon and to firmly grip the edges of the said elements, substantially as described.

3. An edgewise brace for ventilators having jaws adapted to be closed down upon the edges of constituent parts of a ventilator, said jaws being serrated, substantially as described.

4. An edgewise brace for ventilators having jaws adapted to be closed down upon the edges of constituent parts of a ventilator, said jaws being reinforced adjacent the bending points of the jaws, substantially as described.

5. An edgewise brace for uniting the constituent parts of a ventilator, said brace being provided with arms, as 2 and 3, and pairs of jaws adapted to be closed upon and to finally grip the edges of the said parts of a ventilator, substantially as described.



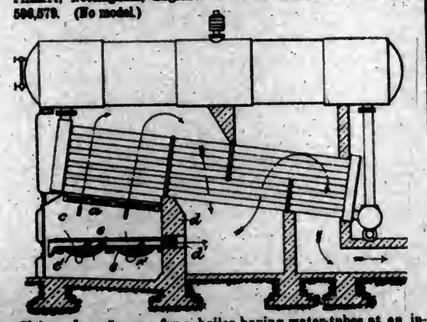
6. An edgewise brace for securing together in their proper relative positions constituent parts of a ventilator, said brace being provided with pairs of jaws, one jaw of each pair made rigid and the other adapted to be bent down, substantially as described.

7. The combination in a ventilator of a neck, two cones, a deflector, and edgewise braces provided with jaws which grip the edges of the neck, cones and deflector and securely hold them in their proper relative positions, substantially as described.

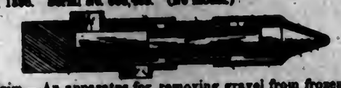
605,509. HINGE. RICHARD G. PARR, West Chester, Pa. Filed Oct. 12, 1897. Serial No. 654,942. (No model.)

Claim.—The herein-described hinge or hinges for oval, elliptical, semi-elliptical, circular or curved window frame and sash, or doors and blinds, having curved leaves provided with twisted arms or offsets, said arms or offsets having knuckles the pin-holes of which register in a right line which is tangential to the curve of said leaves.

605,509.

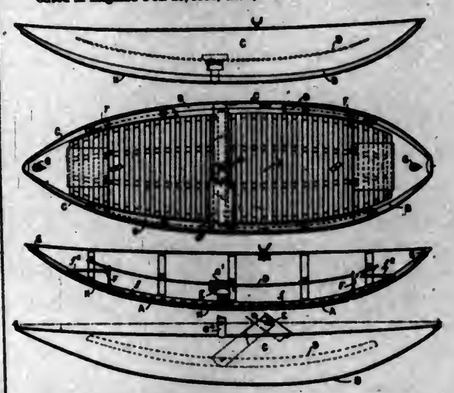


605,510. FASTENING DEVICE. SAMUEL PATCHETT, Easton, Md. Filed Dec. 10, 1896. Serial No. 615,122. (No model.)



Claim.—The combination with two contiguous parts to be connected together, each provided with one or more projecting headed lugs or screws, of a fastening-plate having two or more contracted openings adapted to receive the said screws, the surfaces of the plate at the sides of the contracted portions of the openings being inclined in the direction of the length of the openings whereby when the plate is moved longitudinally, when the screws are in the openings thereof, the two parts will be secured together and simultaneously tightened against the inner face of the plate, substantially as described.

605,511. FURNACE FOR WATER-TUBE BOILERS. ANDREW PILLATT, Nottingham, England. Filed June 23, 1896. Serial No. 596,579. (No model.)



Claim.—In a furnace for a boiler having water-tubes at an inclination above the bridge-wall, a perforated arch of refractory material over the fire-chamber and below the water-tubes of the boiler, the back edge being closely adjacent to the bridge-wall, and hollow grate-bars having inlets for the air passing up from below the grate-bars and opening through the bridge-wall, so that the air is highly heated and combines with the products of combustion as they descend from the perforated arch, substantially as set forth.

605,512. APPARATUS FOR REMOVING GRAVEL FROM FROZEN GROUND. RALPH H. PINKHAM, Wakefield, Mass. Filed Jan. 29, 1898. Serial No. 668,468. (No model.)

Claim.—An apparatus for removing gravel from frozen ground comprising inner and outer pipes terminating in a tapering perforated shoe adapted to be driven into the ground, a hot-water supply communicating with the space between the pipes, said space having outlet-openings, a pump for raising the material through the interior pipe and an intermediate gravel-receptacle between the pump and the tube, substantially as described.

605,513. COLLAPSIBLE BOAT. MILLARD T. READE, Liverpool, England. Filed Dec. 15, 1896. Serial No. 615,790. (No model.) Patented in England Feb. 26, 1896, No. 4,250.

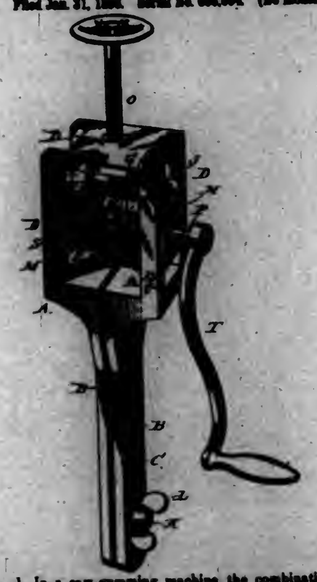
Claim.—1. In a folding boat, the combination of three or more superficially rigid, but longitudinally flexible pieces or sections forming the bottom and main sides, and an intermediate piece or stringer with edge or edges of different shape or curvature to adjacent edge or edges of side and bottom when laid flat, between each main side and the bottom, the said pieces being of such a form that when hinged together and opened out, they form a boat having lines curved lengthwise from end to end, but which when folded, will close up and lie flat in compact form, substantially as described.

2. The combination in a folding boat, of two superficially comparatively rigid, but longitudinally flexible pieces or sections with an intervening stringer between forming the bottom, and two superficially rigid, but longitudinally flexible sections forming the sides, with an intervening stringer between each of them and the bottom, said pieces or sections being of such a form that when hinged together at their adjacent edges, they shall form a boat which can be folded into compact form or opened out when required for use, substantially as described.

3. The combination with a folding boat, of a flexible but superficially comparatively rigid longitudinal stringer so disposed in a curve and hinged to the laterall-bent folding sides, that as the sides straighten in folding the boat, the stringer straightens in unison and folds up against the side, but when the boat is expanded it lies edgewise to the side, and distributes the thrust and tension of the stretcher and seats, substantially as described.

4. In a folding boat, having longitudinal stringers hinged to the main sides inside, the combination therewith of a stretcher in two parts with a central pivot and overlapping ends, the extremities being pin-jointed to the stringer on either side of boat, and adapted to keep the boat open in its extended position, or fold when the boat is collapsed, substantially as set forth.

5. In a folding boat, the combination with the main sides and bottom of bilge-stringers which are located between the sides and bottom of two layers with two layers of waterproof canvas riveted between, the edges of said canvas being bifurcated and riveted over the adjacent edges of the sides and bottom to form a hinge, or hinges, substantially as described.

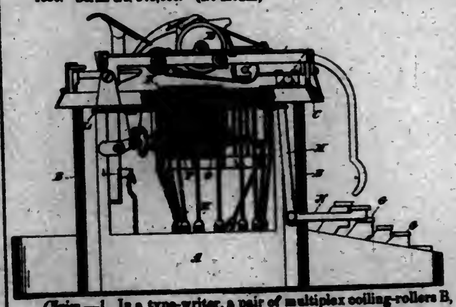


6. In a folding boat, the combination with the sides and bottoms of bilge-stringers which are located between the sides and bottom, of one or more layers in combination with strips of waterproof canvas, the opposite edges of which are secured to the layer or layers at their adjacent edges, forming the subsidiary hinge, and strips of balata belting or other suitable material riveted through the planking on the inner side at the joint to form the hinges proper, substantially as described.

605,514. COMBINATION-LOCK. JOHN REITZENSTEIN, Two Harbors, Minn. Filed Jan. 5, 1897. Serial No. 618,093. (No model.)

Claim.—In a combination-lock the combination of a hasp secured to the lid of a chest or trunk a lock placed on the body of a chest or trunk provided with a dial a turning knob, a hub having a projection 26 extending out and turned over at a right angle, three circular tumblers, two of them having circular holes in their centers one having a slot extending from the central circular hole placed on the hub, two of said tumblers being provided with circular slots adjacent to the center hole for receiving the right-angular projection of the hub, three washers having their ends turned out, placed between said tumblers all of said tumblers having a slot cut in their outer edge into which the hasp adapted to pass said hasp being provided with suitable notches for the tumblers, a suitable casing secured to the face-plate provided with lugs by which the cover is secured, substantially as described and shown.

605,515. SAW-GUMMING MACHINE. ADOLPHUS RIGGS, Kenosha, Wis. Filed Jan. 31, 1898. Serial No. 668,604. (No model.)

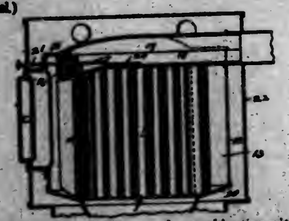


Claim.—1. In a saw-gumming machine, the combination of a frame comprising two main sections provided with depending legs having elongated slots formed therein; a bolt adjustably mounted in said slots; a cutter mounted in the upper portion of the frame; means for raising and lowering the cutter; means for imparting motion thereto; and a gage located to one side of the cutter designed to engage the teeth of the saw-blade.

2. In a saw-gumming machine, the combination of a frame comprising two main sections provided with depending legs having elongated slots formed therein; a bolt adjustably mounted in said slots; a cutter mounted in the upper portion of the frame; means for raising and lowering the cutter; means for imparting motion thereto; slotted arms extending out from the frame at approximately right angles thereto; and an adjustable bolt mounted in said arms.

3. In a saw-gumming machine, the combination of a frame comprising two main sections A provided with depending legs B having elongated slots formed therein; a bolt mounted in said slots; slotted arms H extending out from the frame; a bolt mounted in said arms; a cutter; and means for raising and lowering the cutter, substantially as described.

4. In a saw-gumming machine, the combination of a frame comprising two main sections A provided with depending legs B having elongated slots formed therein; a bolt mounted in said slots; uprights D extending up from sections A; a plate E connecting said sections; sliding blocks M mounted between said uprights and connected by a cross-bar N; a threaded spindle working in said plate E and swiveled in the cross-bar; a shaft journaled in the blocks M; a cutter carried by said shaft; slotted arms H extending out from the frame at right angles thereto; and a bolt mounted in said arms.



605,516. TYPE-WRITER. WILLIAM T. ROBERTSON, Washington, D. C., assignor to John T. Underwood, Brooklyn, N. Y. Filed Jan. 16, 1896. Serial No. 575,660. (No model.)

Claim.—1. In a type-writer, a pair of multiplex coiling-rollers B, having a division between the compartments and constructed and adapted to receive ribbons or inkers coiled upon them in different compartments separated by said division, whereby the coiled parts of the ribbon are kept separate and the exposed part guided, substantially as described.

2. The combination in a type-writer, of a pair of multiplex coiling-rollers constructed to receive and hold ribbons or inkers coiled upon them in separate compartments, in combination with the lever and intermediate connection, substantially as described between said lever and the rollers to give the same endwise motion, as and for the purpose set forth.

605,517. HOT-AIR FURNACE. ROBERT ROBINSON and EDWARD H. ROBINSON, Chicago, Ill. Filed Mar. 22, 1897. Serial No. 630,571. (No model.)

Claim.—1. In a hot-air furnace the combination with a suitable casing, of a series of tubes constituting air-passages and separated at the rear to provide a passage for the products of combustion and from the casing to provide annular passages and a central duct or flue communicating with the front ends of said passages and extending thence rearwardly across the fire-chamber at the top thereof, substantially as described.

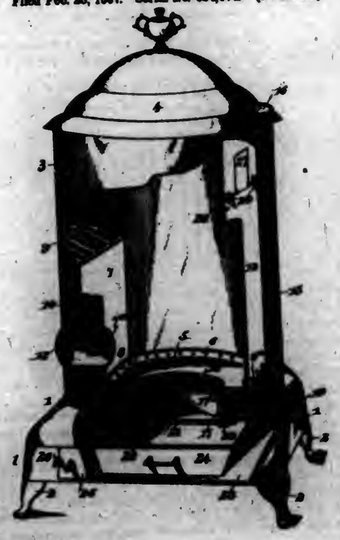
2. In a hot-air furnace the combination with air-tubes arranged in series at the sides of the furnace and the individual tubes being in contact with each other concentrically to the fire-pot, a shell forming with said tubes annular passages and said tubes being separated to provide a rear exit for the products of combustion communicating with said passages, partitions closing the front ends of said annular passages and ducts leading from the front and upper ends of said passages to a central smoke-flue and said flue extending above the

fire chamber and delivering out of the furnace toward the rear thereof, substantially as described.

3. In a furnace of the class described, the combination of a suitable shell or casing, a series of air-tubes separated at the rear to provide a passage for the products of combustion and from the casing to provide annular lateral passages, a central dome and a central flue having its upper portion formed integral with said dome on the lower side thereof and provided with a separable lower portion, and external tubular branches connecting said central flue with the front ends of the lateral passages, substantially as described.

4. The combination with a furnace-dome having a portion of a smoke-flue formed integrally with the lower side thereof, an attachable portion completing said flue, external branches also formed integrally with the dome and a clean-out opening at the junction of said branches and in line with the flue, substantially as described.

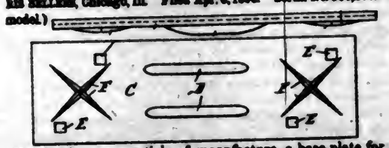
5. In a furnace of the character described, the combination, with a suitable shell or casing and a series of air-tubes therein separated at the rear and forming annular passages within the casing closed at their front ends, of a dome having a smoke-flue on its under side connected at its front end with said annular passages and having an opening in its lower wall near the front end communicating directly with the fire chamber, and a damper controlling said opening, substantially as described.



605,518. BICYCLE-SEAT CLAMP. BENJAMIN S. SEAMAN, Canton, Ohio. Filed Oct. 14, 1897. Serial No. 655,115. (No model.)

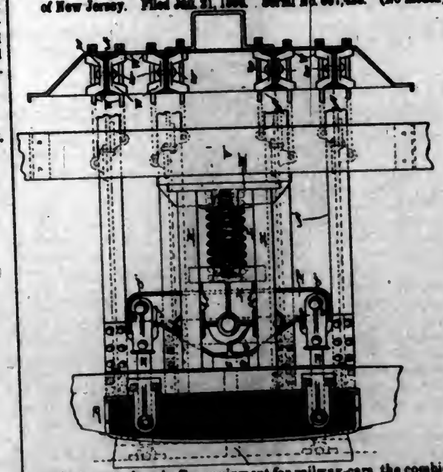
Claim.—1. A clamping-block for bicycle-seat supports, consisting of a clamping head provided with laterally-depending screw-threaded prongs having slotted apertures therein, clamping-bits adapted to pass through said slotted apertures and provided with outwardly-projecting grooved portions to engage the post on either side of the head, and curved grooved inner edges to receive the springs of the seat-support, washers provided with grooves upon their inner surfaces to engage said springs, and screw-threaded binding-nuts to engage the prongs of the clamping-head, substantially as described and for the purpose set forth.

2. The combination in a bicycle-seat support, of a clamping head provided with screw-threaded laterally-projecting prongs having slotted apertures therein, with clamping-bits adapted to pass through said slotted apertures and provided with outwardly-projecting grooved portions to engage the post on both sides of the head and binding-nuts, substantially as described and for the purpose set forth.



605,519. STOVE OR FURNACE. WALLACE J. SELBY, Burr Oak, Mich. Filed Feb. 23, 1897. Serial No. 624,674. (No model.)

Claim.—1. In a heating device comprising a base provided with a horizontal diaphragm 19, the shell mounted upon the base, the horizontal diaphragm 5 arranged within the shell at the bottom thereof and located above the diaphragm 19 said diaphragm 5 terminating short of the sides of the shell, the short vertical partition 7 extending upward from one side of the diaphragm 5, forming a flue and provided at its upper end with a grating, the vertical partition 13 located at the opposite side of the diaphragm 5 and extending to the top of the shell and forming a flue between it and the latter, said partitions 7 and 13 and the shell forming a fire-pot between them, and the depending annular flange 17, located in the space between the diaphragms 5 and 19 and connected with the same and forming an ash-passage, substantially as described.



2. A heating device, comprising a base provided above its bottom with a horizontal diaphragm 19, a shell mounted upon the base, the horizontal diaphragm 5 located within the shell above the base parallel with the diaphragm 19 and terminating short of the sides of the shell, partitions extending upward from the diaphragm 5 and forming with the shell a fire-pot, and the depending annular flange 17 located in the space between the diaphragms 5 and 19 and forming a communication between the base of the stove and the fire-pot, substantially as described.

605,520. BASE-PLATE FOR RAILWAY-RAIL JOINTS. MOSES SELLERS, Chicago, Ill. Filed Apr. 6, 1896. Serial No. 586,260. (No model.)

Claim.—As a new article of manufacture, a base-plate for rail-joints, comprising a plate adapted to rest upon two adjacent cross-ties, having a longitudinal socket on its upper surface to receive the rail and provided on its bottom at the ends thereof with tapering cross-ribs adapted to engage the respective ties, substantially as described.

605,521. BUFFER EQUIPMENT FOR RAILWAY-CARS. HENRY H. SIMMONS, Chicago, Ill., assignor to the Standard Coupler Company, of New Jersey. Filed Jan. 21, 1896. Serial No. 577,428. (No model.)

Claim.—1. In a buffer equipment for railway-cars, the combination with the buffer-plate, the stems therefor and the centrally-pivoted spring-supported equalizer, of substantially straight transversely-arranged bearings interposed between the stems and equalizer whereby a differential leverage is exerted by the equalizer when moved into an inclined position; substantially as described.

2. In a buffer equipment for railway-cars, the combination with the buffer-plate having the rearwardly-extending stems provided with substantially straight horizontal bearing-surfaces at their rear ends, of a centrally-pivoted spring-supported equalizer having substantially straight horizontal bearing-surfaces at its ends on the forward edges for cooperation with the corresponding surfaces on the stems; substantially as described.

3. In a buffer equipment for railway-cars, the combination with the buffer-plate and the rearwardly-extending stems having substantially straight horizontal bearing-surfaces and arms extending rearwardly above and below said bearing-surfaces, of the centrally-pivoted spring-supported equalizer having its ends located between the rearwardly-extending arms on the stems and provided with substantially straight horizontal bearings cooperating with the corresponding bearings on the stems and pins loosely uniting the stems and equalizers; substantially as described.

4. In a buffer equipment for railway-cars the combination with the centrally-pivoted spring-supported equalizer having substantially straight bearing-surfaces on its front edge at the center and each end respectively, of the buffer-plate and the side and central buffer-stems each having a substantially straight horizontal bearing-surface for cooperating with the corresponding bearing-surface on the front edge of the equalizer; substantially as described.

5. In a buffer equipment for railway-cars the combination with the supporting-beams of a depending yoke for the draw-bar adapted to be moved laterally, and a central spring adapted to be put under compression by the movement of the yoke in either direction; substantially as described.

6. In a buffer equipment for railway-cars the combination with the supporting-beams and a laterally-movable yoke depending therefrom, of a central spring and a telescoping connection between said yoke and each end of the spring whereby lateral movement in either direction will put the spring under compression; substantially as described.

7. In a device such as described adapted to be applied to the buffer equipment of railway-cars the combination with the sleeve having the depending yoke for the draw-bar, the thimbles telescoping in said sleeve and the central spring for holding said sleeves extended; substantially as described.

8. The combination with the sleeve having the depending yoke and internal end flanges, of the thimbles having the external end flanges and adapted to telescope with the sleeve, of the central spring for holding said thimbles extended and the bolt for maintaining the parts in position; substantially as described.

9. The combination with the sills of a car-body frame and I-beams passing longitudinally beneath said sills, of I-beam brackets united to the webs of the I-beam by through bolts or rivets and having eyes extending beyond the flanges of the I-beams and supporting or tie bolts passing through said eyes outside of said flanges and into the sills of the car-body framing; substantially as described.

10. The combination with the car-body frame and I-beams of I-beam brackets secured on opposite sides of said I-beam and preferably arranged out of line with each other, of a bolt or rivet passing through the web of the I-beam and through both of said brackets at the point where they overlap and bolts or rivets uniting each of said brackets and said web of the I-beam, said I-beam brackets having lateral projections extending beyond the flanges of the I-beam and tie or supporting bolts passing through said extensions and uniting the I-beams to the car-body frame; substantially as described.

605,522. CENTER-BEARING FOR RAILWAY-CARS. HENRY H. SIMMONS, Chicago, Ill., assignor to the Standard Coupler Company, of New Jersey. Filed Jan. 21, 1896. Serial No. 577,429. (No model.)

Claim.—1. The combination with the truck-bolster mounted on swing-hangers whereby it may move transversely, of swing links or yokes journaled on said bolster and the center-bearing mounted on said swing-links to move transversely; substantially as described.

2. The combination with the truck-bolster or center-bearing support, the channel-irons incorporated therein with their flanges turned outwardly and the swing links or yokes suspended on and between said channel-irons to swing transversely of the car-body, of the center-bearing mounted directly on the depending portions of said swing links or yokes and cooperating with the inner faces of the channel-irons to prevent movement longitudinally of the car; substantially as described.

3. The combination with the truck-bolster or center-bearing support, the swing links or yokes journaled therein and having at their lower portions flattened bearing-surfaces, of the center-bearing resting directly upon said swing links or yokes and having flattened bearing-surfaces cooperating with the flattened bearing-surfaces of the swing links or yokes, whereby the center-bearing is caused to return to its central position; substantially as described.

4. The combination with the truck-bolster or center-bearing support and the swing links or yokes journaled therein and having flat bearing-surfaces on their depending portions, of the center-bearing, the supporting-plate underlying said center-bearing and the recessed bearings on said supporting-plate having flat bearing-surfaces on which the depending portions of the swing links or yokes seat; substantially as described.

5. The combination with the truck-bolster or center-bearing support and the swing links or yokes journaled therein and having the flattened depending portions, of the center-bearing, the supporting-plate underlying the center-bearing and the inverted channel-irons on said supporting-plate, in which channel-irons the flattened portions of the swing links or yokes seat; substantially as described.

605,523. PNEUMATIC TIRE. URBIN P. SMITH, Chicago, Ill. Filed Dec. 20, 1897. Serial No. 664,163. (No model.)

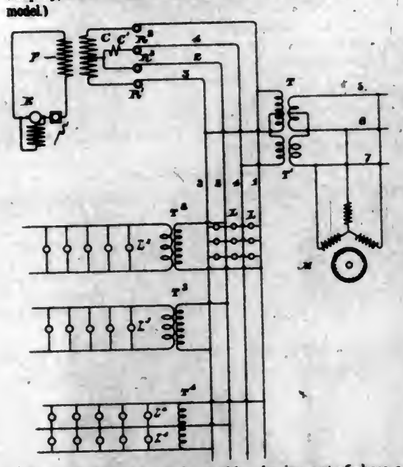
Claim.—As a new article of manufacture, a pneumatic tire provided with an outer sheath slitted circumferentially at its inner surface and provided with two continuous flat metallic flaring bands the inner diameter of which is smaller than the outer diameter of the wheel-rim and embedded in the sheath at or near its lateral edges, and a wheel-rim provided with a concave peripheral groove of larger diameter at its lateral edges than the inner diameters of the flaring rings, substantially as described.

605,524. GRAIN-DRILL. BYRON T. SPILMAN, Jacksonville, Ill. Filed Sept. 23, 1897. Serial No. 652,702. (No model.)

Claim.—1. In a grain-drill, the combination with the main frame, of the independently-pivoted supporting-frames arranged within the main frame and the hopper, the dropper and the operating mechanism arranged within each pivoted frame, substantially as shown and described.

2. In a grain-drill, the combination with the main frame of the independently-pivoted frames arranged within the main frame, the grain-hopper arranged upon each frame, the drum provided with covering-bands, the operating-sprockets and chain and the dropper arranged also in each frame, said dropper being connected to the hopper, substantially as shown and described.

3. In a grain-drill, the combination with the main frame of the independent frames pivoted within the main frame, the hopper and



drum arranged in each frame the discharge and connecting tubes, the delivery-tube and the plows or furrow-openers to which the delivery-tubes are attached, substantially as shown and described.

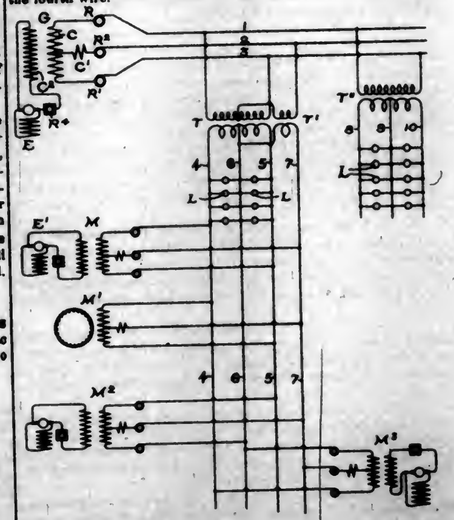
4. In a grain-drill, the combination with the standard of the plow or furrow-opener arranged upon the lower end of said standard and the delivery-tube arranged beneath the said plow or furrow-opener the forward end of said plow being bent downwardly at a point below the forward end of the delivery-tube, substantially as shown and described.

5. In a grain-drill, the combination with the standard of the plow or furrow-opener having the side flanges and the forward end bent downwardly and the delivery-tube arranged upon the under side of the said plow, the bottom of said delivery-tube being pressed inwardly at the forward end, substantially as shown and described.

6. In a grain-drill, the combination with the main frame of the independent frames pivoted within the main frame, the hopper arranged upon each frame, the drum provided with covering-bands, the sprockets and drive-chain, the agitating-shaft having arms sliding cut-off valve, the discharge and connecting tubes, the delivery-tube and furrow opener, the standard to which the said furrow-opener is attached the cross-beam O^3, and the hinge board O^2 through which the standard passes, the hand-lever for raising said standard and the coiled spring surrounding the standard below the hinge-board O^2 all arranged and adapted to operate substantially as shown and described.

605,525. SYSTEM OF ELECTRICAL DISTRIBUTION. CHARLES P. STEINMETZ, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed Jan. 28, 1895. Serial No. 536,441. (No model.)

Claim.—A dynamo-electric machine, having out-of-phase coils connected to three collector-rings, and the remaining terminal of one coil connected to an intermediate point in the second coil, and a fourth collector-ring likewise connected to the intermediate point in the last-named coil.



605,526. SYSTEM OF ELECTRICAL DISTRIBUTION. CHARLES P. STEINMETZ, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed June 17, 1897. Serial No. 641,120. (No model.)

Claim.—1. In a system of electrical distribution, and in combination, a generator having a main coil, and a supplemental coil at an angle thereto connected at one end to an intermediate point in the main coil, a three-wire distribution system fed from the main coil, and a multiphase translating device fed from both coils.

2. In a system of electrical distribution, a source of current having a main coil, and a supplementary coil connected to an intermediate point in the main coil, means for producing an electromotive force of displaced phase in the supplemental coil, a three-wire single-phase distribution system fed from the main coil, and a multiphase translating device fed from both coils.

3. The combination of a source of single-phase currents, a two-wire circuit leading therefrom, a transformer connected to said circuit, a three-wire single-phase system fed from the secondary of the transformer, and a fourth or supplementary wire on which a dephased electromotive force is maintained interconnected with the three-wire system.

4. The combination of a generator of single-phase currents having a main coil, an additional coil on said generator so displaced as to be the seat of an out-of-phase electromotive force, a two-wire circuit leading from said generator to a transformer, a three-wire single-phase system fed from the secondary of the transformer, and a fourth or supplementary wire fed from the said additional coil, and multiphase translating devices fed from the three-wire system and from the fourth wire.

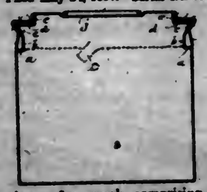
5. The combination of a source of single-phase current, a single-phase three-wire distribution system fed therefrom, a single supplementary wire, and a source of dephased electromotive force connected between the three-wire system and the supplementary wire; single-phase translating devices and multiphase translating devices, the single-phase translating devices being fed from the three-wire system, and the multiphase translating devices being fed from the three-wire system and from the supplemental wire.

6. The combination with the main single-phase armature-winding of an alternating-current generator, of a transformer which on one side is connected to the said armature-winding and on the other side to a single-phase three-wire system, and an additional source of dephased electromotive force connected to the neutral wire of the three-wire system, and to a fourth or supplementary wire which forms, with two wires of the three-wire system, a multiphase distribution system.

7. The combination with an alternating-current three-wire system of a source of dephased electromotive force connected between the neutral wire of said system and a fourth or supplementary wire, single-phase translating devices connected to the three-wire system, and multiphase translating devices connected to the three-wire system and to the supplementary wire, whereby the four said wires form a complete system suitable for the distribution of light and power.

8. The combination with the main armature-winding of a monocyclic generator, of two rings connected to the terminals of said winding, an additional armature-coil connected at one end to an intermediate point on the said winding and at its other end to a third ring, a field-magnet in inductive relation to said armature, connections from two of the first-mentioned rings to a transformer, a three-wire single-phase system fed from the secondary of said transformer, an additional transformer connected at one end to a wire leading from the third ring and at the other end to an intermediate point in the primary of the first-mentioned transformer, a connection from one terminal of the secondary of said additional transformer to the neutral wire of the three-wire system and from the other terminal to a fourth or supplementary wire, single-phase translating devices connected to the three-wire system, and multiphase translating devices connected to the three-wire system and to the fourth or supplementary wire.

605,527. BALL-AND-SOCKET CLAMP. ROBERT E SWARTS, Creston, Iowa, assignor of one-half to H. E. W. Barnes, same place. Filed May 22, 1897. Serial No. 637,771. (No model.)



Claim.—1. The combination with a base-support having a recess, of a plate secured to the base and provided with an opening registering with said recess, threaded bolts secured to and extending upwardly from opposite ends of the said plate, a ball seated in said opening and recess and having a shank adapted to be secured to an object, such as a chair-seat, spaced plates provided with openings to fit over the ball and bolts respectively, means to adjustably support and hold the spaced plates at one end on the bolts, and a head-nut working on the bolt at the other end of the plates to force them simultaneously into tight frictional engagement with the ball, substantially as described.

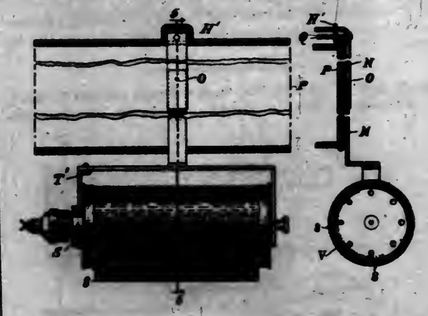
2. The combination with a base-support having a recess, of a plate secured to the base and provided with an opening registering with said recess, a series of threaded bolts secured to and extending upwardly from the said plate at one side, and a single threaded bolt secured to and extending upwardly from the plate at the opposite end, a ball secured in said opening and recess and having a shank adapted to be secured to an object, such as a chair-seat, a pair of spaced plates provided at their opposite ends with openings to fit over the said bolts, and with central openings to fit over the upper portion of the ball and engage it at different points, nuts adjustable on the said series of bolts to support and hold the ends of the spaced plates fitted over them, a thimble fitted over the said single bolt between the spaced plates, and a nut working on the last-named bolt and engaging the upper plate to simultaneously force the spaced plates into tight frictional engagement with the ball, substantially as described.

3. The base provided with a recess for the ball, combined with the ball partially seated therein, an upper or end plate engaging the ball at a point opposite the base, an intermediate plate engaging with the ball between the upper or end plate and the base, bolts rigidly seated in the base and connecting the intermediate plate and the upper or end plate, and means for spacing or separating the intermediate plate from the end plate and also for clamping the parts together, substantially as described.

605,528. CLOSURE FOR VESSELS. FRANCIS A. WALSH, Milwaukee, Wis. Filed May 24, 1897. Serial No. 637,821. (No model.)

Claim.—1. A closure for vessels, comprising a cover having a downward-extending sheet-metal flange, provided with an inward bend or contraction for contact with the exterior surface of the vessel to be closed, and a tongue projecting beyond the lower line of said flange, and united to said flange on a readily-separable line, for forcible detachment therefrom, in the opening of the vessel.

2. The combination with a vessel of a cover having a downward-extending sheet-metal spring-flange provided with an inward bend for wedging contact with the upper exterior part of said vessel on a plane below the top thereof, said top being of greater diameter than that at the place of contact, whereby the said cover is held in place by mere contact, but incapable of removal without partial destruction thereof, and a tongue projecting from said flange and united thereto on a readily-separable line, for forcible detachment in the said destructive removal of the cover.



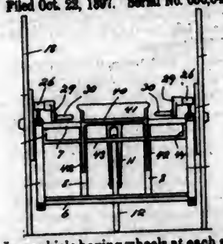
3. The combination with a vessel provided with an outwardly-flaring flange having an inwardly-extended portion terminating in a longitudinally-extended collar, of a cover having a longitudinally-extended portion conforming to said collar, an outwardly-extended portion in line with and extending beyond the projection of the said inwardly-extended portion and a downwardly-extended flange provided with an inward bend or contraction for contact with the said outwardly-flaring vessel-flange.

4. The combination with a vessel provided with an outwardly-flaring flange having an inwardly-extended portion terminating in a longitudinally-extended collar, of a gasket surrounding said collar and a cover having a longitudinally-extended portion conforming to said collar and an outwardly-extended portion in line with and extending beyond the projection of the said inwardly-extended portion, and in contact with said gasket, and terminating in a downwardly-extended flange provided with an inward bend or contraction for contact with the said outwardly-flaring vessel-flange.

5. The combination with a vessel provided with an outwardly-flaring flange having an inwardly-extended portion terminating in a longitudinally-extended collar, of a cover having a longitudinally-extended portion conforming to said collar and an outwardly-extended portion in line with and extending beyond the projection of the said inwardly-extended portion and terminating in a downwardly-extended flange, provided with an inward bend or contraction for contact with the said outwardly-flaring vessel-flange, and said cover-flange having a tongue projecting therefrom, and united thereto on a readily-separable line, the said cover being held in place by mere contact, but incapable of removal without partial destruction thereof, and the said tongue affording the means for the said destructive removal of the cover.

6. The combination with a vessel provided with an outwardly-flaring portion, of a cover having a downwardly-extending sheet-metal flange provided with an inward bend or contraction for contact with the exterior surface of said outwardly-flaring portion of said vessel, a ring or gasket of suitable flexible material, interposed between the said vessel and cover, and means for the ready separation of a portion of the said flange when the cover is to be removed from the vessel.

605,529. DESK-LAMP. WILLIAM R. WARD, Montclair, N. J. Filed Jan. 2, 1897. Serial No. 617,798. (No model.)



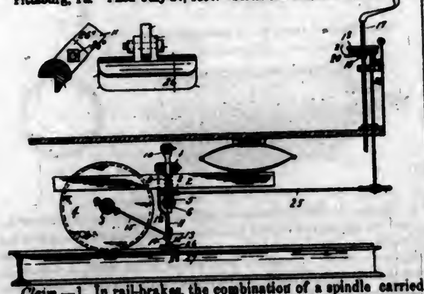
Claim.—1. The combination with the supporting-bracket, of the casing having capped ends, a set-screw adjustably connecting one end thereof to the bracket, the other one of said caps being provided with a flanged opening by which it is journaled in the bracket, set-screws passing through said flange, and an incandescent-lamp socket removably held in place by said screws.

2. The combination with the bracket, of the outer semicylindrical shell mounted thereon and adjustable about its axis and provided with the reflecting projection S, the detached complementary opaque shell or shield mounted within the outer shell and axially adjustable therein irrespective of the adjustment of the outer shell and provided with the reflecting projection S, circular caps covering the ends of said outer shell and serving to confine the complementary shell within the outer one, and the electric-lamp socket secured in one of said caps, substantially as set forth.

3. A lamp-supporting bracket consisting of the arm N, having a portion thereof bent downwardly, the clip H', fitted to slide upon said downwardly-bent portion and projecting along the other portion, and a clamping-screw passing through the arm and clip, substantially as and for the purpose set forth.

4. The combination with the supporting-yoke provided with a set-screw in one end and a bearing in the other, of a lamp-casing pivoted at one end upon said set-screw and provided at the other with means for holding the socket of an electric light and for projecting into said bearing to serve as a trunnion for the casing, substantially as set forth.

605,530. TRICYCLE FOR INVALIDS. CHARLES A. WAY, Charlestown, N. H. Filed Oct. 22, 1897. Serial No. 656,042. (No model.)



Claim.—1. In a vehicle having wheels at each side thereof, outer and inner gear-wheels carried by each of said wheels and concentric therewith, a gear-pinion mounted in a fixed position and in gear with said inner gear-wheel, and a driving gear-pinion movably supported between said outer and inner gear-wheels whereby it may be thrown into gear with either.

2. In a vehicle having wheels at each side thereof, outer and inner gear-wheels carried by each of said wheels and concentric therewith, a gear-pinion mounted in a fixed position and in gear with said inner gear-wheel, and a driving gear-pinion carried by a lever pivotally mounted upon the frame of the vehicle and situated between said outer and inner gear-wheels, and an operating-lever connected with said lever.

3. A tricycle for invalids, consisting of a frame which is provided centrally of its opposite sides with main side wheels, a seat mounted centrally of said frame, pinions connected with the hubs of the side wheels, circular gears connected with said side wheels concentrically of said pinions, and provided with internal gear-teeth, pinions supported rearwardly of the hubs of said wheels and adapted to operate in connection with the pinions on said hubs, pivoted standards in front of the hubs of said wheels and provided with pinions, cranks mounted on the shafts of said pinions and rods connected with said standards and projected backwardly and connected with levers pivotally connected with the frame, and segmental rack-bars in connection with which said levers operate, substantially as shown and described.

605,531. CAR-BRAKE. JESSE S. WICKES and JOHN KETTERLY, Pittsburg, Pa. Filed July 27, 1897. Serial No. 646,137. (No model.)

Claim.—1. In rail-brakes, the combination of a spindle carried by the truck-frame and capable of vertical movement; brake-rods pivoted to the upper extremity of said spindle and extending obliquely toward the rails and capable of longitudinal motion, and shoes on the lower extremities of said brake-rods capable of bearing against the upper and inner faces of said rails.

2. In rail-brakes, the combination of a spindle carried by the truck-frame; brake-rods pivoted to the upper extremity of said spindle and extending in an oblique direction toward the rails and capable of longitudinal motion, shoes on the ends of said brake-rods capable of bearing against the upper and inner faces of said rails, and means for moving said spindle in a vertical direction.

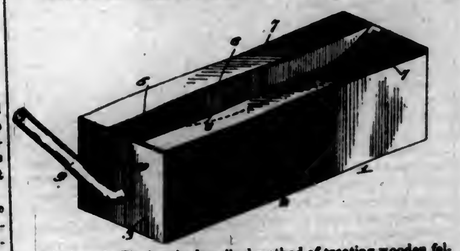
3. In rail-brakes, the combination of a threaded spindle carried vertically by the truck-frame; brake-rods pivoted to said spindle and extending in an oblique direction toward the rails; shoes on the lower extremities of said brake-rods capable of bearing against the rails; a power-wheel, internally threaded, mounted to travel on said spindle, a coiled spring encircling said spindle, interposed between said truck-frame and said power-wheel, and a second power-wheel operatively connected with said first power-wheel and revoluble from the car.

4. In rail-brakes, the combination of a spindle mounted in the truck-frame; brake-rods pivoted to said spindle and extending in an oblique direction toward the rails; braces extending from the truck-frame to said brake-rods and having a sliding connection therewith; additional braces journaled on the car-axle and connecting with said first braces, and means for moving said spindle in a vertical direction.

5. In rail-brakes, the combination of a hand-wheel, a shaft revoluble by said hand-wheel; a power-wheel mounted on said shaft; a vertically-moving threaded spindle carried by the truck-frame; a second power-wheel internally threaded and mounted on said threaded spindle; brake-rods pivoted to the upper extremity of said spindle and extending obliquely toward the rail, and brake-shoes on the lower extremities of said brake-rod adapted to bear against the rail.

605,532. PNEUMATIC TIRE. WILLIS S. WILLIAMS, London, England. Filed Dec. 20, 1897. Serial No. 662,591. (No model.) Patented in England Jan. 29, 1897, No. 2,427.

Claim.—1. In a tire, the combination, with a cover C, of a series of blocks arranged inside the cover and having wide bases and narrow projecting tread portions, the said cover being stretched to conform to the said tread portions, the said blocks and cover both having sharp or angular corners at the edges of their tread portions for preventing side slip, and a band secured to the bases of the said blocks, substantially as set forth.

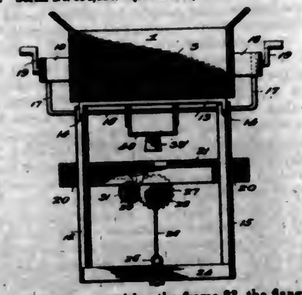


2. In a tire, the combination, with a cover C, of a series of blocks arranged inside the cover and having wide bases and narrow projecting tread portions, the said cover being stretched to conform to the said tread portions, a band secured to the bases of the said blocks, and a series of metallic plates secured over the said tread portions outside the said cover, substantially as set forth.

605,533. SHOE-BRUSH. WILLIAM W. WORCESTER, Jeffersonville, Ind. Filed Aug. 19, 1897. Serial No. 648,818. (No model.)

Claim.—As an improved article of manufacture, a brush, provided with a series of rows of bristles 2, convolutions of fabric 3, covering said bristles and wires 6, set between the rows of bristles to hold the convolutions in place, substantially as described.

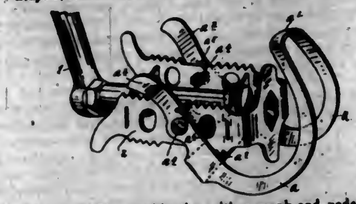
605,534. METHOD OF TIGHTENING TIRES. JOHN W. ALLEN, Davis, Ind. Ter. Filed Dec. 2, 1896. Serial No. 614,234. (No model.)



Claim.—1. The herein-described method of treating wooden fellies, the same consisting in submerging the felly in boiling water for swelling the same, and then submerging the felly in boiling oil having combined therewith a soluble filling agent, substantially as described.

2. The herein-described method of treating wooden fellies, the same consisting of revolving the same in boiling water and thereafter submerging or revolving the same in boiling oil impregnated with gum-arabic and resin, whereby the oil is caused to expel the water and fill the interstices of the felly with the gum-arabic and resin, the latter serving when hardened, to prevent the contraction of the felly to its normal size, substantially as described.

3. A method of treating wooden fellies, consisting in swelling the wood and then forcing therein heated oil having combined therewith a soluble filling agent, substantially as described.



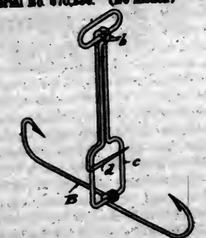
4. A method of treating wooden fellies, consisting in swelling the wood and then forcing therein heated oil containing a soluble filling agent such as resin and gum-arabic, substantially as described.

605,535. CHUTE-WAGON. CHARLES BERNHARDT, Philadelphia, Pa., assignor of one-half to Julius Kaufmann, same place. Filed Sept. 16, 1897. Serial No. 651,827. (No model.)

Claim.—A vehicle, comprising the frame 23, the flanged rollers 22 horizontally mounted in said frame, the turn-table 21 revolubly mounted on said rollers, the horizontal shaft 27 journaled in said frame, the parallel rods 15 15 having bearing in said table, the bar 24 connecting said rods, and the chain 26 connecting said bar and shaft 27, in combination with the body 1, centrally hinged to the upper ends of said rods, and means, as described, for supporting said body in an inclined position, when elevated, substantially as and for the purpose set forth.

605,536. CLIP FOR BICYCLE-PEDALS. ALFRED L. REED, Minneapolis, Minn. Filed July 20, 1896. Serial No. 600,472. (No model.)

Claim.—1. The combination with a crank and pedal, of a clip pivoted to said pedal, transversely of the pedal's axis, with its center of gravity on one side of its own pivot and substantially in a vertical plane passing through the axis of said pedal which clip is provided, at its light end, with a part normally projecting above the working face of the pedal, and, at its heavy end, with a shoe or foot clamping portion, whereby, when out of use, said clip will throw and hold said pedal right side up, and when stepped upon, will engage the rider's foot, substantially as described.



2. The combination with a crank and pedal, of a clip pivoted to said pedal, transversely of the pedal's axis, with its center of gravity on one side of its own pivot and substantially in a vertical plane passing through the axis of said pedal which clip is provided, at its light end, with a part normally projecting above the working face of the pedal, and, at its heavy end, with a shoe or foot clamping portion, and a spring tending to throw said clip into its normal position, whereby, when out of use, said clip will throw and hold said pedal right side up, and when stepped upon, will engage the rider's foot, substantially as described.

3. The combination with a crank and pedal, of a clip pivoted to said pedal, transversely of the pedal's axis, with its center of gravity on one side of its own pivot and substantially in a vertical plane passing through the axis of said pedal, the light end of which clip normally projects above the working face of the pedal, and the heavy end of which clip is curved upward and inward and is adapted to transversely engage the top of the rider's foot; whereby, when out of use, said clip will throw and hold said pedal right side up, and when stepped upon, will engage the rider's foot, substantially as described.

605,537. INSECTICIDE. JOSEPH B. CARMICHAEL, Benita, Tex. Filed Feb. 26, 1898. Serial No. 672,071. (No specimens.)

Claim.—An insecticide consisting of cyanid of potash, camphor, benzin, turpentine, ether, oil of sassafras, oil of spike, in about the proportions hereinbefore set forth.

605,538. ANGLING DEVICE. JAMES J. DEMPSEY, Hartford, Wis., assignor of one-half to Adolph G. Loubenstein, same place. Filed Feb. 14, 1898. Serial No. 670,236. (No model.)

Claim.—1. An angling device comprising a hanger having a lower loop portion, a bait-pin crosswise of the loop, and a shank in pivotal connection with said loop having fish-hook terminals.

2. An angling device comprising a hanger having a lower loop portion, a pin crosswise of the loop but free at one end for impalement of bait when sufficient clearance is had, and a shank in pivotal connection with said loop having fish-hook terminals.

3. An angling device comprising a line-attaching link, a single wire bent to form link-engaging eyes, a loop and a bait-pin crosswise of the loop; together with a shank in pivotal connection with said loop having fish-hook terminals.

4. An angling device comprising a bait-holder, and a double fish-hook having pivotal connection with the bait-holder and extending in opposite directions therefrom.

605,539. BRAKE. ANTOINE DESILETS, Montreal, Canada, assignor to William James Lewis, same place. Filed Sept. 20, 1897. Serial No. 652,587. (No model.)

Claim.—1. In combination with a car-truck, a car-brake comprising a brake-shoe, mounted upon one end of a suitably-supported sliding bar and located in close proximity to the periphery of the wheel to which it is to be applied, a shaft mounted transversely of the truck, a cam mounted upon said shaft, means for causing the free end of said sliding bar to normally yieldingly bear upon said cam, means actuated by the rotation of said wheel for rotating said shaft, for the purpose set forth.

2. In combination with the truck of a car, a car-brake comprising a brake-shoe, mounted upon one end of a suitably-supported slid-

ing bar, and located in close proximity to the periphery of the wheel to which it is to be applied; a shaft mounted transversely of the truck; a cam mounted rigidly upon said shaft, means for causing the free end of said sliding bar to normally bear upon said cam; a hub mounted rigidly upon said shaft; an arm extending laterally from and connected rigidly to said hub; and means for operatively connecting said arm to one of the axles of the truck whereby said arm and with it said shaft may be oscillated to either side of the vertical according to the direction of rotation of the wheels mounted upon said axle, for the purpose set forth.

3. In combination with the truck of a car, a car-brake comprising a brake-shoe mounted upon one end of a suitably-supported sliding bar, and located in close proximity to the periphery of the wheel to which it is to be applied; a shaft mounted transversely of the truck; a cam mounted rigidly upon said shaft, means for causing the free end of said sliding bar to normally bear upon said cam; a hub mounted rigidly upon said shaft; an arm extending laterally from and connected rigidly to said hub; and means comprising a buffer-section for operatively connecting said arm to one of the axles of the truck whereby said arm and with it said shaft may be oscillated to either side of the vertical according to the direction of rotation of the wheels mounted upon said axle, for the purpose set forth.

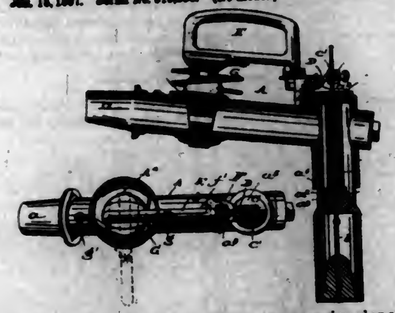
4. In combination with the truck of a car, a car-brake comprising a brake-shoe mounted upon one end of a suitably-supported sliding bar, and located in close proximity to the periphery of the wheel to which it is to be applied; a shaft mounted transversely of the truck; a cam mounted rigidly upon said shaft, means for causing the free end of said sliding bar to normally bear upon said cam; a hub mounted rigidly upon said shaft; an arm extending laterally from and connected rigidly to said hub; a pinion mounted loosely upon one of the axles of the truck and having one of its ends formed with a clutch-face; a clutch-block mounted loosely upon but keyed to said axle; a toothed rack adapted to intermesh with said pinion and operatively connected to the aforesaid arm; and means for shifting said clutch-block into and out of engagement with the clutch-face of said pinion, for the purpose set forth.

5. In combination with the truck of a car, a car-brake comprising a brake-shoe mounted upon one end of a suitably-supported sliding bar, and located in close proximity to the periphery of the wheel to which it is to be applied; a shaft mounted transversely of the truck; a cam mounted rigidly upon said shaft, means for causing the free end of said sliding bar to normally bear upon said cam; a hub mounted rigidly upon said shaft; an arm extending laterally from and connected rigidly to said hub; a pinion mounted loosely upon one of the axles of the truck and having one of its sides formed with a clutch-face; a clutch-block mounted loosely upon but keyed to said axle; a toothed rack adapted to intermesh with said pinion, and operatively connected to the aforesaid arm; a lever leaving one end forked to straddle and take into a groove in the clutch-block, and the other end fulcrumed to the truck-frame, a cross-bar secured upon and transversely of said lever, the end of said cross-arm being connected to the lower end of a vertical lever mounted upon the end of the truck, substantially as described and for the purpose set forth.

6. In combination with the truck of a car, a car-brake comprising a brake-shoe mounted upon one end of a suitably-supported sliding bar, and located in close proximity to the periphery of the wheel to which it is to be applied; a shaft mounted transversely of the truck; a cam mounted rigidly upon said shaft, means for causing the free end of said sliding bar to normally bear upon said cam; a hub mounted rigidly upon said shaft; an arm extending laterally from and connected rigidly to said hub; and means including a buffer-section, for operatively connecting said arm to one of the axles of the truck whereby said arm and with it said shaft may be oscillated to either side of the vertical according to the direction of rotation of the wheels mounted upon said axle, for the purpose set forth.

7. In combination with the truck of a car, a car-brake comprising a brake-shoe mounted upon one end of a suitably-supported sliding bar, and located in close proximity to the periphery of the wheel to which it is to be applied; a shaft mounted transversely of the truck; a cam mounted rigidly upon said shaft, means for causing the free end of said sliding bar to normally bear upon said cam; a hub mounted rigidly upon said shaft; an arm extending laterally from and connected rigidly to said hub; a pinion mounted loosely upon one of the axles of the truck and having one of its sides formed with a clutch-face; a clutch-block mounted loosely upon but keyed to said axle; a toothed rack adapted to intermesh with said pinion and connected to a buffer-section which is connected to the aforesaid arm; and means for shifting said clutch-block into and out of engagement with the clutch-face of said pinion, for the purpose set forth.

8. In combination with the truck of a car, a car-brake comprising a brake-shoe mounted upon one end of a suitably-supported sliding bar, and located in close proximity to the periphery of the wheel to which it is to be applied; a shaft mounted transversely of the truck; a cam mounted rigidly upon said shaft, means for causing the free end of said sliding bar to normally bear upon said cam; a hub mounted rigidly upon said shaft; an arm extending laterally from and connected rigidly to said hub; a pinion mounted loosely upon one of the axles of the truck and having one of its sides formed with a clutch-face; a clutch-block mounted loosely upon but keyed to said axle; a toothed rack adapted to intermesh with said pinion and connected to a buffer-section consisting of a sleeve having one end permanently closed and pivotally connected to the aforesaid arm, a rod connected rigidly at one end to said rack and having its other end located within said sleeve and provided with a head, a cap adapted to take over said rod and close the open end of said sleeve, and a spiral spring encircling the portion of said rod within said sleeve and bearing between said cap and the head of said rod; a lever having one end forked to straddle and take into a groove in the clutch-block and the other end fulcrumed to the truck-frame, a cross-bar secured upon and transversely of said lever, the end of said cross-arm being connected to the lower end of a vertical lever mounted upon the end of the truck, substantially as described, and for the purpose set forth.



9. In combination with the truck of a car, a car-brake comprising a brake-shoe mounted upon one end of a suitably-supported sliding bar, and located in close proximity to the periphery of the wheel to which it is to be applied; a shaft mounted transversely of the truck; a cam mounted rigidly upon said shaft, means for causing the free end of said sliding bar to normally bear upon said cam; a hub mounted rigidly upon said shaft; an arm extending laterally from and connected rigidly to said hub; a pinion mounted loosely upon one of the axles of the truck and having one of its sides formed with a clutch-face; a clutch-block mounted loosely upon but keyed to said axle; a toothed rack adapted to intermesh with said pinion and connected to a buffer-section consisting of a sleeve having one end permanently closed and pivotally connected to the aforesaid arm, a rod connected rigidly at one end to said rack and having its other end located within said sleeve and provided with a head, a cap adapted to take over said rod and close the open end of said sleeve, and a spiral spring encircling the portion of said rod within said sleeve and bearing between said cap and the head of said rod; a lever having one end forked to straddle and take into a groove in the clutch-block and the other end fulcrumed to the truck-frame, a cross-bar secured upon and transversely of said lever, the end of said cross-arm being connected to the lower end of a vertical lever mounted upon the end of the truck, for the purpose set forth.

10. In combination with the truck of a car, a car-brake comprising a brake-shoe mounted upon one end of a suitably-supported sliding bar, and located in close proximity to the periphery of the wheel to which it is to be applied; a shaft mounted transversely of the truck; a cam mounted rigidly upon said shaft, means for causing the free end of said sliding bar to normally bear upon said cam; a hub mounted rigidly upon said shaft; an arm extending laterally from and connected rigidly to said hub; a pinion mounted loosely upon one of the axles of the truck and having one of its sides formed with a clutch-face; a clutch-block mounted loosely upon but keyed to said axle; a toothed rack adapted to intermesh with said pinion and connected to a buffer-section consisting of a sleeve having one end permanently closed and pivotally connected to the aforesaid arm a rod connected rigidly at one end to said rack and having its other end located within said sleeve and provided with a head, a cap adapted to take over said rod and close the open end of said sleeve, and a spiral spring encircling the portion of said rod within said sleeve and bearing between said cap and the head of said rod; a lever having one end forked to straddle and take into a groove in the clutch-block and the other end fulcrumed to the truck-frame, a cross bar secured upon and transversely of said lever, the end of said cross-arm being connected to the lower end of a vertical lever mounted upon the end of the truck, for the purpose set forth.

11. The combination of a car-truck comprising a truck-frame, a series of axles mounted transversely of said frame, and a pair of wheels mounted rigidly upon each of said axles; a shaft mounted transversely of said truck-frame and centrally thereof; a pair of cam-disks mounted rigidly upon said shaft and in line with said wheels; two pairs of sliding bars mounted in brackets carried upon said truck-frame one pair being located at each side of the frame; a brake-shoe mounted upon one end of each of said bars and located in close proximity to the periphery of one of the wheels the other end of each of said bars being located in contact with one side of one of the cams means for maintaining said bars in constant yielding contact with said cams; a hub mounted rigidly upon said shaft an arm extending laterally from and connected rigidly to said hub; a pinion mounted loosely upon one of the axles of the truck and having one of its ends formed with a clutch-face; a clutch-block mounted loosely upon but keyed to said axle; a toothed rack adapted to intermesh with said pinion and connected to a buffer-section consisting of a sleeve having one end permanently closed and pivotally connected to the aforesaid arm, a rod connected rigidly at one end to said rack and having its other end located within said sleeve and provided with a head, a cap adapted to take over said rod and close the open end of said sleeve, and a spiral spring encircling the portion of said rod within said sleeve and bearing between said cap and the head of said rod; a lever having one end forked to straddle and take into a groove in the clutch-block and the other end fulcrumed to the truck frame, a cross-bar secured upon and transversely of said lever, the end of said cross-arm being connected to the lower end of a vertical lever mounted upon the end of the truck, substantially as described, and for the purpose set forth.

12. The combination of the truck S; brake-shoes 5, sliding bars 6, bearing-sections 9, with bearing-faces 10; shaft 11; cam-disks 12; springs 13; hub 14; arm 15; sleeve 16; rod 17; collar 18; spring 19; cap 20; rack 22; rod 23; bracket 41; spring 25; pinion 26; clutch-face 28; axle 27; clutch-block 29; lever 30, 33, 35, 36; rods 37, 38; lever 39; bracket 40; roller 42; rods 45, 46; chain 47; crank-spindle 48; ratchet 49 and pawl 50, all arranged substantially as described and for the purpose set forth.

605,540. AUTOMATIC FAUCET. JOHN HARKER, Cedar Rapids, Iowa, assignor of one-half to William B. Douglas, same place. Filed Jan. 18, 1897. Serial No. 619,858. (No model.)

Claim.—In an automatic faucet, a casing, a turning plug contained therein, a spring-actuated handle secured to and projecting from the turning plug, a depending projection carried by the outer free end of the handle, a post projecting upwardly from the casing, a horizontally-arranged catch pivotally secured upon the upper end thereof and having a limited rotative movement, a float, a lever actuated thereby when the float is lowered to normally hold the catch in its rotated position in one direction and a projection extending upwardly from the catch against which the projection upon the turning-plug handle abuts against the tension of the spring, for holding the handle in parallel alinement with the casing and consequently the turning plug in an open position, substantially as described.

605,541. SOCKET-JOINT OR COUPLING FOR RODS, &c. JOSEPH BUNBAIN, London, England. Filed Dec. 28, 1897. Serial No. 663,877. (No model.)

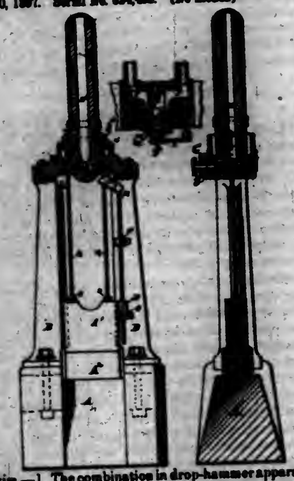
Claim.—In a rod-coupling, the combination of the socket-pieces, one of which is adapted to receive the other and provided with undercut edges, and a set-screw having expansible wings which engage under the said undercut edges of the socket-piece, substantially as described.

605,542. CAR-WHEEL. JAMES FAIRFIELD, Manchester, N. H. Filed May 17, 1897. Serial No. 636,930. (No model.)

Claim.—A car-wheel composed of a body portion and a hub, the former being provided with a central tapering aperture and with an integral annular shoulder surrounding said aperture and provided with projections and bolt-holes, and the latter being tapering in form and adapted to the central aperture, and provided with an annular flange having recesses adapted to receive the projections of the body portion, and bolt-holes registering with the bolt-holes of the body portion, and bolts passing through the annular flange of the hub and the annular shoulder of the body of the wheel, substantially as set forth.

605,543. BOUQUET-HOLDER. SAMUEL C. FERGUS, Wenona, Ill. Filed Nov. 16, 1897. Serial No. 658,085. (No model.)

Claim.—1. A bouquet holder formed of two opposing trough-shaped sections arranged to clamp positively the stems of flowers, the edges of which sections overlap each other and are hinged together at their lower ends and provided with interlocking devices at their upper ends, said sections forming a tube when locked together, and a pad of absorbent material supported in each section, said pads forming a yielding clamp for the stems of the flowers, substantially as described.



2. A bouquet-holder formed of two opposing trough-shaped sections formed of spring sheet metal and arranged to clamp positively the stems of flowers, the edges of which sections overlap each other and are hinged together at their lower ends, and provided with interlocking devices at their upper ends adapted to be sprung into or out of engagement, said sections forming a tube when locked together, and a pad of absorbent material supported in each section, said pads forming a yielding clamp for the stems of the flowers, substantially as described.

3. A bouquet-holder formed of two opposing trough-shaped sections, the edges of which overlap each other and are hinged together at their lower ends and provided with interlocking devices at their upper ends, said sections forming a tube when locked together, and a pad of absorbent material supported in each section, said pads forming a yielding clamp for the stems of the flowers, combined with a clamp adjustably connected to one of the sections of said holder, substantially as described.

4. A bouquet-holder comprising two substantially trough-shaped sections closed at their lower ends and hinged together at that point at the inner edges of the sections, said sections being adapted to swing apart and capable of positively clamping the stems of the flowers, substantially as described.

5. A bouquet-holder comprising two substantially trough-shaped sections hinged together at their lower ends adjacent to their inner edges and adapted to swing apart, and the absorbent pads mounted within the trough-shaped sections and adapted to engage the stems of flowers, whereby the latter are supplied with moisture and a yielding engagement is effected, substantially as described.

605,544. DROP-HAMMER. ROBERT J. GOSS, Watertown, N. Y., assignor to the Stiles & Field Press Company, of New York. Filed Feb. 20, 1897. Serial No. 624,462. (No model.)

Claim.—1. The combination in drop-hammer apparatus, of a movable cylinder, a hammer operatively connected therewith, a stationary piston provided with a steam-passage delivering into the cylinder, a

chamber communicating with the said steam-passage, a three-way valve in said chamber controlling the movement of steam through said passage, and devices on said hammer adapted to throw said valve, substantially as described.

2. The combination in a drop-hammer apparatus, of a movable cylinder constructed of tubing with a spherical end and a stationary ported piston therein, substantially as described.

3. The combination in a drop-hammer apparatus, of a stationary ported piston, a valve controlling the distribution of the operating fluid through said piston, a cylinder adapted to work on said piston, a hammer operatively connected with said cylinder, a valve-operating rod, and adjustable collars thereon adapted to be actuated by the hammer, substantially as described.

4. The combination in a drop-hammer apparatus of the type described, of a movable cylinder consisting of a closed-end tube, a stuffing-box sleeve on the open end of said tube and provided with bosses, a hammer, and rods connecting said hammer with said stuffing-box sleeve and said rods being threaded at one end and headed at the other end, substantially as described.

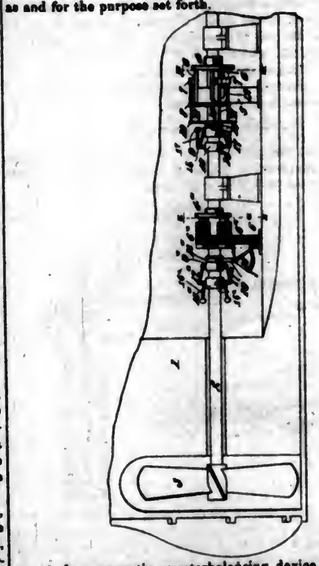
5. The combination in a drop-hammer apparatus, of the type described, of a movable cylinder, a hammer, rods connecting the hammer with the cylinder, chambers in the hammer in which the ends of said rods work, and thrust-cushions in said chambers, substantially as described.

6. The combination in a drop-hammer apparatus, of a hammer, a wedge surface thereon, a valve controlling the movement of the hammer, a valve-operating rod, a stationary support for said rod, adjustable collars on said rod and at least one of said collars having a wedge surface adapted to be engaged by the wedge surface on the hammer, whereby the rod is pushed off the support, substantially as and for the purpose described.

7. The combination in a drop-hammer apparatus, of a hammer, a wedge surface thereon, a valve controlling the movement of the hammer, a valve-operating rod, a stationary support for said rod, adjustable collars on said rod at least one of which has a wedge surface adapted to be engaged by the wedge surface on the hammer for pushing the rod off the support, a lever controlled by the operator and adapted to receive and support said rod, whereby the operator may control the valve independently of its operation by the movement of the hammer, substantially as described.

8. The combination in a drop-hammer apparatus, of a hammer, a trigger device for sustaining the hammer, means controlled by the operator for throwing the trigger device to release the hammer, and a spring tending to throw the said trigger device in the opposite direction to that of release, substantially as described.

9. The combination in a drop-hammer apparatus, of a hammer, a hook thereon, a vertically-adjustable movable hook, a spring adapted to press the movable hook into engagement with the hook on the hammer, and devices controlled by the operator for releasing the movable hook from the hook on the hammer, substantially as described.



10. The combination in drop-hammer apparatus, of a hammer, a hook thereon, a movable hook adapted to engage with the hook on the hammer, a cam for releasing the movable hook, a spring for moving the movable hook in the direction opposite to that of release, and devices controlled by the operator for moving the cam so as to release the movable hook, substantially as described.

605,545. FRICTION-LESSENING DEVICE AND BRAKE FOR PROPELLER-SHAFTS. GEORGE M. GUERRANT, Danville, Va., assignor of two-thirds to Charles O. Evans and John M. Sheppard, St. Louis, Mo. Filed Mar. 3, 1897. Serial No. 625,909. (No model.)

Claim.—1. In combination with a propeller-shaft, a friction-lessening and braking device comprising a disk or collar fixed upon the shaft and magnets located adjacent to the shaft in the line of the face of said disk or collar so as to draw longitudinally thereon and in position to contact with said disk for producing a braking effect, substantially as herein explained.

2. In combination with a propeller-shaft; a magnetic counterbalance operating upon said shaft in a direction opposite to the end thrust resulting from resistance of the water to the propeller, and consisting of a suitable armature disposed circumferentially about the shaft, a similarly-disposed magnetic field in inductive relation to the side of the armature toward the propeller, and means regulated by the velocity of the shaft, for varying the effect of the magnetic field upon the armature, substantially as and for the purposes set forth.

3. In a combined end-thrust counterbalance and brake to prevent racing; the combination with a propeller-shaft, of a disk of magnetic material fixed upon said propeller-shaft, one or more magnets arranged in inductive relation to said disk on the side toward the propeller, and in such proximity to said disk as to cause contact and produce a braking effect when a strong attractive force is exerted, and means under control of the shaft for varying the degree of magnetic action of said magnet or magnets upon said disk, substantially as and for the purpose set forth.

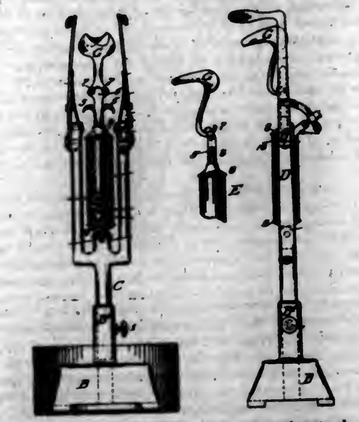
4. In a magnetic counterbalancing device for propeller-shafts, the combination of an armature, fixed upon said shaft, magnets arranged in proximity to said armature and in position to attract the same in a direction opposite to the end thrust of the shaft, means for controlling the degree of magnetic action of said magnets, and a governor actuated by the shaft for operating said controlling means, substantially as and for the purpose set forth.

5. In a device of the character described, the combination with a propeller-shaft of a disk carried thereby, magnets arranged in proximity to said disk and having their poles opposed thereto, armatures arranged to slide upon said magnets, and a governor arranged to control the movement of said armatures, substantially as and for the purpose set forth.

6. In a device of the character described, the combination with a propeller-shaft, of a disk carried thereby, magnets arranged in proximity to said disk and having their poles opposed thereto, armatures arranged to slide upon said magnets, a loose collar on said propeller-shaft, a fixed collar on said shaft, weighted arms carried by said fixed collar, links connecting said weighted arms to said loose collar, and rods forming a connection between said loose collar and said armatures, substantially as and for the purpose set forth.

7. In combination with a propeller-shaft, an end-thrust counterbalance, a centrifugal governor whereby said counterbalance is actuated by the rotation of said propeller-shaft, and a clutch which uncouples said governor when the shaft reverses, as herein explained.

8. In combination with a propeller-shaft, an end-thrust counterbalance substantially as herein described, a centrifugal governor for actuating said counterbalance from the propeller-shaft, and a toothed clutch one member of which is loose upon the propeller shaft and carries the centrifugal governor, and the other member of which is keyed on the propeller-shaft but longitudinally movable thereon, and is spring-pressed against the member first named, whereby the counterbalance operates only when the shaft rotates to send the vessel forward, as explained.



605,546. ELASTIC WHEEL-TIRE. WILLIAM HANCOCK, JOHN C. HANCOCK, and EDMONDSON SCHOLES, Hollinwood, England, assignors of two-fifths to John Edward Lees and Frederick Newton Tweedale, Oldham, England. Filed Jan. 26, 1896. Serial No. 577,268. (No model.)

Claim.—1. The improved means for positively actuating and locking the extensible flexible ribbon *a* for securing resilient tires, said means consisting of a screwed spindle formed with right and left hand threads engaging with nuts formed on or secured to said ribbon *a* to which screwed spindle is secured a connection made flexible by means of universal joints, the outer protruding end of the flexible connection being arranged to revolve within a sleeve secured to the rim and operated by means of a key so as to revolve the screwed spindle whereby the flexible ribbon *a* is expanded or contracted in diameter for the purposes and substantially as set forth.

2. In combination the ribbon *a* for securing resilient tires, the nuts *b c* formed on or secured to the ribbon *a* the screwed spindle *d* formed with right and left hand screw-threads engaging with the nuts *b c*, the flexible connection *f* and protruding link *f'* revolving within a sleeve *j'* secured to the rim *e*, and dust-cap *m* arranged and acting in the manner for the purposes and substantially as set forth.

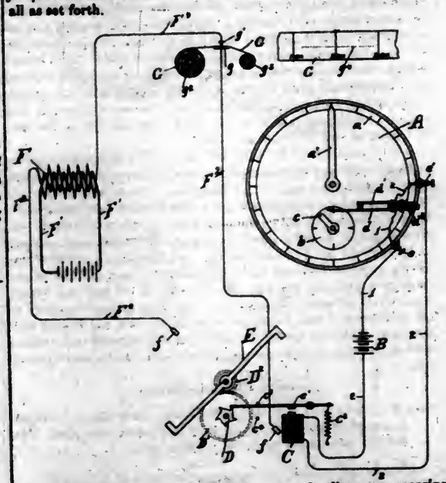
605,547. VAGINAL DILATOR. ALEXANDER F. HOLLAND, Berkeley, Cal. Filed Apr. 26, 1897. Serial No. 634,269. (No model.)

Claim.—1. In combination, the vertical supporting-standard having a forked upper end, a dilating-arm removably pivoted to the upper end of each fork, springs for pressing said arms apart, and means for independently adjusting each arm to any desired degree upon the fork, substantially as described.

2. In combination, the forked standard, the elastic dilating-arms carried upon the extremities of the fork, the vertically-movable spring-pressed support, and the speculum flexibly connected to said support, substantially as described.

3. In combination, the vertical supporting forked standard, a vertical elastic dilating-arm secured to the upper end of each fork and having a lateral wing at its upper end, a vertically-movable member between the arms, and a blade or speculum secured to said vertically-movable member, substantially as described.

4. In a dilator and in combination, a forked standard, a spring-actuated dilating-arm connected to each fork, a cylinder pivoted between the forks, a spring-actuated stem within said cylinder and means for attaching a speculum to said stem.



5. In a dilator the combination with the forks of the supporting-standard, of dilating-arms, having slotted lower ends and pivot-pins, upon which said arms are mounted, whereby said arms can be adjusted and removed, and means for locking said arms at different adjustments.

6. In a dilator, and in combination, a forked support, a dilating-arm pivoted to each fork and removable therefrom, a quadrant secured to each arm, and a bolt carried by each fork and adapted to lock the quadrant and arm at different adjustments

---

605,548. ELECTRIC RECORDING INSTRUMENT. CHARLES L. JAGER, Maywood, N. J. Filed Aug. 5, 1897. Serial No. 647,160. (No model.)

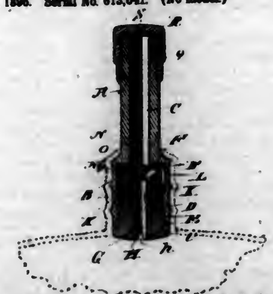
Claim.—1. In a speed indicator and recorder, the combination with an electric circuit, a magnet forming part of the same, and means for closing and breaking said circuit, two contacts adapted to be connected and disconnected instantly by the armature of said magnet, an induction-coil terminating in said contacts and having a break, and means for moving a strip through the break, whereby the making and breaking of the circuit through said coil will cause sparks to jump across its break and through the strip making holes in the same, all as set forth.

2. In combination with the moving arm of a distance-measuring or speed-indicating device, of an electric circuit adapted to be closed and broken by said arm, a magnet forming part of said circuit, two contacts adapted to be connected and disconnected instantly by the armature of said magnet, an induction-coil terminating in said contacts and having a break, and means for regularly moving a strip through the break; whereby the making and breaking of the circuit through said coil will cause sparks to jump across its break and through the strip making holes in the same, all as set forth.

3. In combination with the moving arm of a distance-measuring or speed-indicating device, of an electric circuit adapted to be closed and broken by said arm, a magnet forming part of said circuit, two contacts adapted to be connected and disconnected instantly by the armature of said magnet, an induction-coil terminating in said contacts and having a break, and means for moving a strip divided into sections of equal lengths through the break the length of each section in a certain time; whereby the making and breaking of the circuit through said coil will cause sparks to jump across its break, and through the strip, making holes in the same, all as set forth.

4. In combination with the moving arm of a distance-measuring or speed-indicating device, of an electric circuit adapted to be closed and broken by said arm, a magnet forming part of said circuit, a toothed wheel adapted to be rotated by said armature, a revolving contact-arm caused to rotate by the rotation of said wheel, two contact-plates adapted to be connected by said arm at a certain point of its revolution, an induction-coil terminating in said plates and having a break, and means for moving a strip through said break, all combined and operating in the manner set forth.

5. In combination with the moving arm of a distance-measuring or speed-indicating device, of an electric circuit adapted to be closed and broken by said arm, a magnet forming part of said circuit, a toothed wheel engaging with said armature and adapted to be operated by the same, the gear D' adapted to rotate in unison with said wheel, the pinion D^2 engaging with said gear, the diametric arm E mounted to revolve in unison with said pinion, the contacts *f f*, an induction-coil terminating in said contacts, and a recording device adapted to be operated by making and breaking the circuit of said coil, all as set forth.



6. In combination with the moving arm of a distance-measuring or speed-indicating device, said arm being adapted to travel in two opposite directions, of three contact-plates, one being between the other two and extending over the course of said arm, two electric circuits each having the middle plate for one terminal and the two other plates for the other terminals respectively, two magnets adapted to be respectively vitalized by the closing of the two circuits, an induction-coil having a branch line, and the two terminals of said coil and branch being provided with contacts, and said contacts of the coil and branch being respectively adapted to be connected and disconnected instantly by the armatures of the respective magnets, and a recording device adapted to be operated by making and breaking the circuits of said coil and branch, all as set forth.

7. In combination with the moving arm of a distance-measuring or speed-indicating device, said arm being adapted to travel in two

opposite directions, of three contact-plates, one being between the other two and extending over the course of said arm, two electric circuits each having the middle plate for one terminal and the other two plates for the other terminals respectively, two magnets adapted to be vitalized by the closing of the two circuits, an induction coil having a branch line, and the two terminals of said coil and branch being provided with contacts, and said contacts of the coil and branch being respectively adapted to be connected and disconnected instantly by the armatures of the respective magnets, the coil and branch each having a break, and means for moving a strip through said breaks, all combined and operating as set forth.

8. In combination with the moving arm of a distance measuring or speed-indicating device, said arm being adapted to travel in two opposite directions, of three contact-plates, one being between the other two and extending over the course of said arm, two electric circuits each having the middle plates for one terminal and the two other plates for the other terminals respectively, two magnets adapted to be vitalized by the closing of the two circuits, an induction-coil having a branch line and the two terminals of said coil and branch being provided with contacts; the contacts of the coil and branch respectively adapted to be connected and disconnected instantly by the armatures of the respective magnets, the coil and branch each having a break, and means for moving a strip through said breaks a uniform distance in a certain time, all combined and operating as set forth.

605,549. VALVE GUSTAF JOHANSSON, Jersey City, N. J., assignor to himself, Willard P. Smith, and De Witt Romaine, same place. Filed Nov. 21, 1896. Serial No. 613,041. (No model.)

Claim.—1. In a valve of the class described, the combination with a suitable hollow valve-stem or inlet-pipe, of an imperforate elastic valve-disk normally under rigid mechanical annular pressure so as to close the inlet but adapted to yield by compression of its own substance at the point of annular pressure under the pressure of incoming fluid so as to allow of the entrance of the fluid to the receptacle past the annular seat or seats at the point or points of compression, substantially as shown and described.

2. In a valve of the class described, the combination with a hollow valve-stem or inlet-pipe A having the longitudinal passage C and the enlarged bottom chamber D, of a plug G secured in the end of the chamber D so formed as to leave a passage L, such plug having the cup shaped cavity I at the top, and passages H and K, and a suitable valve or disk N located in the chamber D between the inner end of the plug G and the passage above the same, substantially as shown and described and for the purposes set forth.

3. In a valve of the class described, the combination with a hollow valve-stem or inlet-pipe A having the longitudinal passage C and the enlarged bottom chamber D of a plug G secured in the end of the chamber D, and provided with a small-sized upper portion so as to leave an annular space L, surrounding the same when in position in the chamber D, also having the cup-shaped cavity I at the top, and passages H and K, and a suitable valve-disk N of a soft flexible material such as rubber located in the chamber D between the inner end of the plug G and the passage above the same, substantially as shown and described and for the purposes set forth.

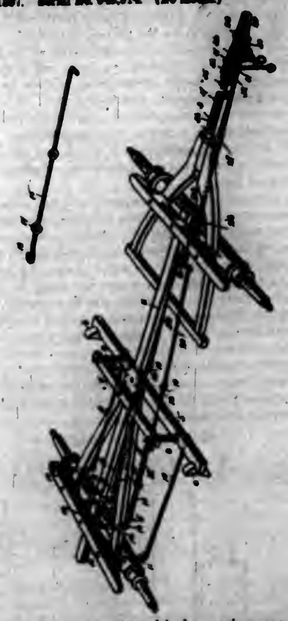
4. In a valve of the class described, the combination with a spindle or valve-stem A having the longitudinal passage C and the enlarged bottom chamber D, of a plug G secured in the inner end of the chamber D and provided with a space or passage L and cup-shaped cavity I at the top, and passages H and K, the passage H communicating with the central portion of the cavity I and the passage or passages K with the space or passage L and passage H, and a suitable valve or disk N located in the chamber D between the inner end of the plug G and the passage above the same, substantially as shown and described and for the purposes set forth.

5. In a valve of the class described, the combination with a spindle or valve-stem A having the longitudinal passage C and the enlarged bottom chamber D, of a plug G secured in the inner end of the chamber D and provided with a space or passage L and cup-shaped cavity I at the top, and passages H and K, the passage H communicating with the central portion of the cavity I and the passage or passages K with the annular space L and passage H, and a suitable valve-disk N of a soft flexible material such as rubber located in the chamber D between the inner end of the plug G and the passage above the same, substantially as shown and described and for the purposes set forth.

6. In a valve of the class described, the combination with a hollow valve-stem or inlet-pipe having a bottom chamber at the top of which bottom chamber is an inward-faced valve-seat, of a plug secured in said bottom chamber having a valve-seat faced toward the first-named valve-seat, an imperforate valve-disk of compressible elastic material normally compressed between the two valve-seats, and a passage or passages formed in or through the plug for the entrance of the fluid to the receptacle when the elastic compressible valve-disk is compressed by the pressure of the incoming fluid, substantially as shown and described and for the purposes set forth.

7. In a valve of the class described, the combination with a hollow valve-stem or inlet-pipe having a bottom chamber at the top of which bottom chamber is an inward-faced valve-seat, of a plug having a central passage secured in said bottom chamber and having a valve-seat faced toward the first-named valve-seat and a central depression within the valve-seat, an imperforate valve-disk of compressible elastic material normally compressed between the two valve-seats, and a passage or passages formed in or through the plug for the entrance of the fluid to the receptacle when the elastic compressible valve disk is compressed by the pressure of the incoming fluid, substantially as shown and described and for the purposes set forth.

8. In a valve of the class described, the combination with a hollow valve-stem or inlet-pipe having a bottom chamber at the top of which bottom chamber is an inward-faced valve-seat, of a plug secured in said bottom chamber having a valve seat faced toward the first-named valve-seat, an imperforate valve-disk of compressible elastic material normally compressed between the two valve-seats, and means for permitting the fluid forced through the inlet-pipe and between the valve-seat at the top of the chamber and the valve-disk to thereafter pass to the rear of the plug, substantially as shown and described.



9. In a valve of the class described, the combination with a hollow valve-stem or inlet-pipe having a bottom chamber at the top of which bottom chamber is an inward-faced valve-seat, of a plug secured in said bottom chamber having a valve-seat faced toward the first-named valve-seat, an imperforate valve-disk of compressible elastic material normally compressed between the two valve-seats, means for permitting the fluid forced through the inlet-pipe and between the valve-seat at the top of the chamber and the valve-disk to thereafter pass to the rear of the plug, and means for transmitting the back pressure of the fluid within the receptacle to the rear of the valve-disk so as to force the same against the valve-seat at the top of the chamber, substantially as shown and described.

605,550. SAW-JOINTER. RUFUS D. KIRK, Bowman, Ga. Filed Dec. 16, 1897. Serial No. 662,125. (No model.)

Claim.—A saw-jointer comprising the yoke 2, formed with the integral parallel arms 3 4, having the alined shoulders 6 6, in combination with the guide plates 9 and 10 formed with the enlarged orifices 13 13, the thumb-screws 11 11′ and 12 12′ provided with collars 14, and adapted to secure said guide-plates to said arms so that the former may be both laterally and longitudinally adjustable thereon, the set-screw 8 secured in said yoke, and the file-blade 7 adjustably secured on said shoulders by said set-screw 8, substantially as shown and described.

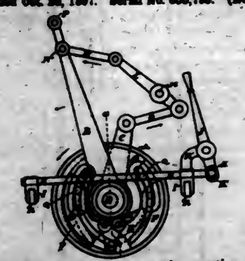
605,551. WAGON-BRAKE. JOHN R. KINKADE, Geneva, Ky. Filed July 26, 1897. Serial No. 645,914. (No model.)

Claim.—1. The combination with the running-gear of a wagon, of brake mechanism, rods extending from the brake mechanism forwardly to the front of the pole, a movable ring mounted on the front of the pole and to which said rods are attached, inclined guides on the pole, and a stay-chain connected to said guides and ring, substantially as and for the purpose specified.

2. The combination with the running-gear of a wagon, of brake mechanism, including brake-chains, rods connected to the brake mechanism and extending forwardly to the pole, a ring movably engaging the front end of the pole and to which said rods are connected, inclined guides on the pole, stay-chains attached to said ring and guides and adapted to be connected to harness, and means for limiting the movement of the ring to permit backing of the vehicle, substantially as described.

3. The combination with the running-gear of a wagon, of brake mechanism, rods connected therewith and extended forwardly to the front end of the pole, a ring movably engaging said front end of the pole to which said rods are attached, a chain connected to said ring, means for adjusting said chain and ring, and stay-chains attached to said ring and adapted to be connected to harness, substantially as described.

4. The combination with the running-gear of a wagon, of the brake beam or rod having brake-shoes thereon, a rock-shaft connected to said brake-beam, rods attached to pendent arms on said rock-shaft, a ring movably engaging the front end of the pole and to which the front ends of said rods are connected, a stay-chain connected to said ring, and means for suspending said stay-chains separate from said pole-ring, substantially as described.



5. The combination with the running-gear of a wagon, of a rock-shaft 12 having pendent arms secured to the brake beam by suitable connecting-rods, pendent lever-arms 14, rods extending from said lever-arms, and having their forward portions connected with a ring sliding on the front end of the pole, stay-chains connected with said ring, pendent chains connected with said stay-chains and movable on angle-irons connected with the pole, and means connected with said pole-ring for limiting its throw for preventing the application of the brakes in backing the vehicle, substantially as described.

605,552. COMBINED FOOT SCRAPER AND WIPER. ISRAEL KINSEY, Detroit, Mich., assignor to Joseph S. Stockwell, Edward M. Weatherhead, Frederick W. Durrant, and Edward P. H. Pearson. Filed Feb. 14, 1898. Serial No. 670,280. (No model.)

Claim.—In a foot scraper and wiper, the combination of the plate, the scraper on said plate, the frame at the end of said plate, the bar formed integral therewith and extending across the opening in said frame, the wiping material extending under said bar and over the sides of said frame, as set forth.

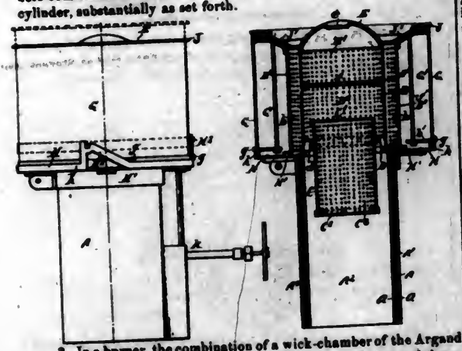
605,553. DEVICE FOR CONVERTING MOTION. GEORGE R. LAIDLAW, Marion, Ind., assignor of two-fifths to Lee Stevens, same place. Filed Oct. 20, 1897. Serial No. 655,795. (No model.)

Claim.—1. In a device for converting motion, the combination with a pulley, of a lever rotatably secured on the hub of the pulley, oppositely-extending clutch-shoes having one of their ends pivoted to the lever and their free ends adapted to bear against the inner surface of the pulley and adapted to rotate the pulley when the lever is moved in one direction and have a sliding contact with the pulley when the lever is moved in the opposite direction, and means for disengaging one of the shoes or both of the shoes from operative contact with the surface of the pulley.

2. In a device for converting motion, the combination with a pulley, of a pair of reciprocating levers, oppositely-extending clutch-shoes having one end pivotally secured to each lever and adapted to engage the inner surface of the pulley, and means for disengaging all of the shoes or one of the shoes of each lever from operative contact with the inner surface of the pulley

3. In a device for converting motion, the combination with a rotatable pulley, of a pair of reciprocating levers, oppositely-extending clutch-shoes pivotally secured to each lever and adapted to engage the pulley, and shifting rods engaging the shoes to disengage all of the shoes or one of the shoes of each lever from operative contact with the pulley.

4. In a device for converting motion, the combination with a rotatable pulley, of a pair of reciprocating levers, oppositely-extending clutch-shoes pivotally secured to the levers and adapted to engage the inner surface of the pulley, shifting rods slidingly secured, and curved links engaging each shoe for disengaging them from operative contact with the pulley.

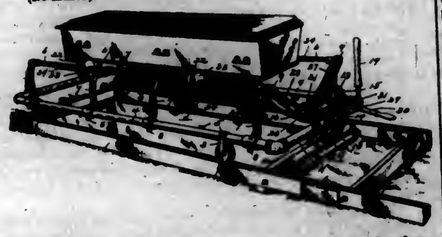


5. In a device for converting motion, the combination with a rotatable pulley, of a pair of reciprocating levers, oppositely-extending clutch-shoes having one end pivotally secured to the levers and adapted to engage the inner surface of the pulley and on opposite sides of the inner surface thereof, and means for disengaging the corresponding shoe of each lever from operative contact with the surface of the pulley.

6. In a device for converting motion, the combination with a rotatable pulley, of a pair of reciprocating levers, oppositely-extending clutch-shoes adapted to engage the inner surface of the pulley and having one end pivotally secured to the levers, a projection on the opposite ends of the shoes, sliding shifting rods, curved links secured to the rod and adapted to engage the projections on the shoes adapted to guide the shoes into operative contact with the pulley or disengage them from the pulley.

605,554. HYDROCARBON-BURNER. JAMES M. MERRITT and BENJAMIN F. GOODRICH, Homer, Mich.; said Merritt assignor to said Goodrich. Filed June 28, 1898. Serial No. 598,403. (No model.)

Claim.—1. In a burner, the combination of a wick-chamber of the Argand type, forming an interior air-chamber, foraminous walls located above the wick-chamber forming a combustion-chamber therebetween, an interior air-chamber formed by and within the inner wall, a foraminous cylinder at the adjacent ends of said air-chambers, said two air-chambers communicable the one with the other through said cylinder, substantially as set forth.

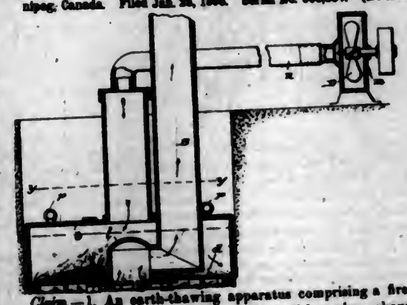


2. In a burner, the combination of a wick-chamber of the Argand type, forming an interior air-chamber, foraminous walls located above the wick-chamber, forming a combustion-chamber therebetween, an interior air-chamber formed by and within the inner wall, a foraminous cylinder provided with solid heads at the top and bottom thereof, located at the adjacent portions of said two air-chambers, said cylinder spaced from the interior walls of the wick-chamber and the combustion-chamber, and a diaphragm located exterior to said cylinder to divert the circulation of air through said cylinder, said air-chambers communicable the one with the other through said foraminous cylinder, substantially as set forth.

3. In a burner, the combination of a wick-chamber of the Argand type, forming an interior air-chamber, foraminous walls located thereabove, forming a combustion-chamber therebetween, an interior air-chamber formed by and within the inner wall, a foraminous cylinder located at the adjacent ends of said air-chambers, through which said air-chambers communicate, the one with the other, and a cap located above the air-chamber within the combustion-chamber, said cap provided with an opening to permit the circulation of air therethrough, substantially as set forth.

4. In a burner, the combination with foraminous walls or tubes B, B', of a cylinder or casing G thereabout, forming an air-chamber therebetween, a top plate J connecting said cylinder or casing to said foraminous walls, and a perforated plate H at the base of said air-chamber, said plate formed with cam-flanges H^3, and said casing or cylinder G provided with lugs g to ride on the upper edge of said flanges to lift the cylinder or casing, substantially as set forth.

605,555. **BURIAL APPARATUS.** CHARLES L. MOORE and CORTES V. POAN, Bowling Green, Mo. Filed May 18, 1897. Serial No. 637,065. (No model.)

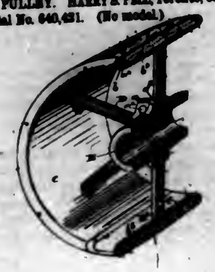


Claim.—1. In a burial apparatus, the combination of a frame comprising longitudinal bars to come upon opposite sides of the grave, knees having bearings at both ends and mounted at their inner ends upon the said longitudinal bars to slide and turn thereon to secure any longitudinal adjustment and to spread their free ends more or less, means for securing the knees in an adjusted position upon the frame-bars, longitudinal shafts parallel with each other and with the side frame-bars, mounted in the bearings at the free or outer ends of the knees, and actuating mechanism applied to the frame for simultaneously turning the shafts at equal speed, substantially in the manner set forth.

2. In a burial apparatus, the combination of a rectangular frame, knees mounted to turn and slide upon side bars of the frame, means for securing the knees in an adjusted position, parallel shafts mounted in bearings at the free ends of the knees, spools adjustable on said shafts and caused to revolve therewith at any adjusted position by a feather-and-spline connection, actuating mechanism for positively rotating the shafts in reverse directions at an equal rate of speed, a detent and a brake device applied to the actuating mechanism, and straps or tapes having their end portions secured to and wound in reverse directions upon corresponding or transversely-alining spools, substantially as set forth for the purpose described.

3. In a burial apparatus, the combination of longitudinally-disposed shafts, straps or tapes having their end portions reversely wound upon the said shafts, intermeshing pinions having sprocket-pinions revolving therewith, sprocket-chains for connecting the sprocket-pinions with corresponding sprocket-pinions on the ends of the longitudinal shafts, a detent mechanism applied to one of the pinions for holding the mechanism in check, and actuating mechanism for positively operating the said pinions, substantially as and for the purpose set forth.

4. In a burial apparatus, the combination of a frame, longitudinal shafts journaled upon the frame, straps or tapes having their end portions reversely wound upon the shafts, a sleeve secured upon a frame-bar and having extensions, a shaft journaled in the extensions and provided with a gear-wheel and a pinion, the latter having a hub portion formed with spurs, a pawl for engaging with the spurs, a ring on the side of the gear-wheel, a strap engaging with the ring, a lever having the strap connected therewith, a second pinion meshing with the first-mentioned pinion, sprocket-pinions revolving with the aforesaid pinions and connected by means of sprocket-chains with sprocket-pinions on the said longitudinal shafts, and a crank having a pinion operatively connected therewith and adapted to be thrown in and out of mesh with the said gear-wheel, substantially as set forth for the purpose described.



605,556. **THAWING APPARATUS.** ROBERT B. ORMISTON, Winnipeg, Canada. Filed Jan. 26, 1898. Serial No. 668,237. (No model.)

Claim.—1. An earth-thawing apparatus comprising a fire-box having a side wall and a bottom wall disposed in a plane above the lower edge of said side wall so as to form an inclosed space between said bottom wall and the ground and also having an open passage between the edge of said bottom wall and the side wall, a suitable blower connected with the interior of the fire-box, and a smoke-pipe connected with the space below the bottom of the fire-box at the center thereof and extending through said fire-box, substantially as specified.

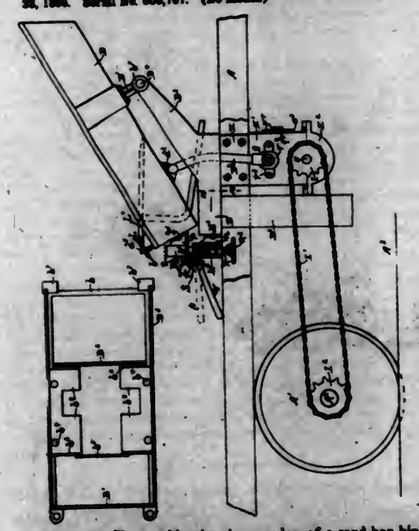
2. An earth-thawing apparatus comprising a fire-box having its bottom wall disposed in a plane above the lower edge of its side wall so as to form an inclosed space between said bottom wall and the ground and also having an annular passage between the edge of said bottom wall and the side wall, an aperture in the center of its bottom wall, and partition-strips connected to and depending from its bottom wall and forming ways intermediate of the annular passage and the central aperture, a smoke-pipe connected with the central aperture in the bottom wall of the fire-box, and a blower connected with the interior of the fire-box, substantially as specified.

605,557. **PULLEY.** HARRY S. PELL, Toronto, Canada. Filed June 12, 1897. Serial No. 640,631. (No model.)

Claim.—1. In combination in a pulley, the belt-face of light material, and a metal sheathing having side flanges, and beaded edges fitting the edges of said light material, substantially as described.

2. In a pulley, in combination the face provided with edge flanges, and the broad cross-notches made across the interior wall of the face, the spoke cross-heads fitting into such notches, the interior sheathing having retaining edges to hold the face in place the spokes and means for connecting the spokes to the cross-heads as and for the purpose specified.

3. In a pulley, in combination the face provided with edge flanges, and the broad cross-notches made across the interior wall of the face, the spoke cross-heads having threaded central bosses, the interior sheathing through which the bosses extend and the tubular spokes into which the threaded bosses extend and a suitable hub to receive the inner ends of the spokes as and for the purpose specified.



4. In a pulley, in combination the face provided with edge flanges, and the broad cross-notches made across the interior wall of the face, the spoke cross-heads fitting into such notches, the interior sheathing having retaining edges to hold the faces in place the spokes and means for connecting the spokes to the cross-heads and the hub divided on the plane of the axes of the spokes and having flanges and bolts for securing the two parts of such hub together as and for the purpose specified.

5. In a pulley in combination, the face provided with edge flanges, the broad cross-notches made across the interior wall of the face, the spoke cross-heads fitting into such notches and provided with inwardly-turned lips designed to embrace the flanges, the spokes suitably secured to the same and the interior sheathing through which the spokes extend as and for the purpose specified.

6. In a pulley, in combination, the face provided with the inner circumferential edge flanges and the outer circumferential edge grooves located within the flanges and the interior sheathing provided with the edge flanges and beads at their inner ends fitting within the grooves of the edges of the face, the spokes, and hub, and means for connecting the spokes to the interior sheathing as and for the purpose specified.

7. A rim for a pulley comprising a metal interior sheathing having inwardly-turned flanges reinforced by being turned back upon themselves and a filling of suitable material for such chamber forming the belt-face, said reinforced edges extending up flush with the face of said filling and over the edge thereof, substantially as described as and for the purpose specified.

605,558. **TRACK-SANDER.** CHARLES V. ROTH, Lancaster, Pa., assignor of one-half to Richard Blickenderfer, same place. Filed July 26, 1896. Serial No. 600,767. (No model.)

Claim.—1. The combination, in a sander, of a sand-box hinged to a support, a cam-wheel, and a brush connected with the sand-box and at one side of the hinged support, the brush bearing against the cam-wheel and acting, approximately, in line with its connection with the sand-box, for the purpose specified.

2. The combination, in a sander, of a sand-box hinged to a support, a cam-wheel, and a rigid brush connected with the sand-box and at one side of the hinged support, the brush bearing against the cam-wheel and acting, approximately, in line with its connection with the sand-box, for the purpose specified.

3. The combination, in a sander, of a sand-box hinged to a support, a cam-wheel, a brush connected with the sand-box and at one side of said hinged support, the brush being located vertically, approximately, beneath its connection with the sand-box and bearing downward on the cam-wheel, for the purpose specified.

4. The combination, in a sander, of a sand-box hinged to a support, a cam-wheel, a rigid brush connected with the sand-box and at one side of said hinged support, the brush being located vertically, approximately, beneath its connection with the sand-box and bearing downward on the cam-wheel, for the purpose specified.

5. The combination, in a sander, of a sand-box hinged to a support, a cam-wheel, and uprightly-disposed brush connected with the sand-box and at one side of the hinged support, the brush bearing downward on the cam-wheel, for the purpose specified.

6. The combination, in a sander, of a sand-box hinged to a support, a cam-wheel, an uprightly-disposed rigid brush connected with the sand-box and at one side of the hinged support, the brush bearing downward on the cam-wheel, for the purpose specified.

7. The combination, in a sander, of a sand-box hinged to a support, a cam-wheel having the swell thereof terminating in an abrupt shoulder, a brush connected with the sand-box and at one side of said hinged support, the brush bearing downward on the cam-wheel, for the purpose specified.

8. The combination, in a sander, of a sand-box hinged to a support, a cam-wheel having the swell thereof terminating in an abrupt shoulder having the face thereof approximately radial to the axis of said cam-wheel, a brush connected with the sand-box and at one side of the hinged support, the brush bearing downward on the cam-wheel, for the purpose specified.

9. The combination, in a sander, of a hinged sand-box, a reciprocating rod, a cam-wheel adapted to impart motion to the reciprocating rod when the sander moves in one direction and a cam-wheel adapted to impart motion to said rod when the sander moves in the opposite direction, and an actuating connection between the reciprocating rod and the sand-box, for the purpose specified.

10. The combination, in a sander, of a hinged sand box, a reciprocating rod, a cam-wheel below the reciprocating rod, a rigid brush on said reciprocating rod and adapted to be engaged by the cam-wheel, and an actuating connection between the reciprocating rod and the sand-box, for the purpose specified.

11. The combination, in a sander, of a hinged sand-box, a reciprocating rod, a wheel below the reciprocating rod, provided on its periphery with a cam having a sloping face and a shoulder, a rigid brush on said reciprocating rod and adapted to bear on the periphery of the cam-wheel, and an actuating connection between the reciprocating rod and the sand-box, for the purpose specified.

12. The combination, in a sander, of a hinged sand-box, a revoluble reciprocating rod, wheels below said rod, provided on their peripheries with cams having shoulders and sloping faces, the sloping face and shoulder of the cam of one wheel being set in the direction opposite to those on the other wheel, rigid brushes set at an angle with each other on said rod, one of said brushes being located above each wheel, the brushes being adapted to alternatively engage the peripheries of the cam-wheels beneath them, and an actuating connection between said rod and the sand-box, for the purpose specified.

13. The combination, in a sander, of a hinged sand-box, a case, a revoluble reciprocating rod having its bearing in slots in the ends of the case, wheels below said rod, provided on their peripheries with series of cams having shoulders and sloping faces, the shoulders and sloping faces of the cams of one wheel being set in a direction opposite to those on the other wheel, rigid brushes set at an angle with each other on said rod, one of said brushes being located above each wheel, the brushes being adapted to alternatively engage the peripheries of the cam-wheels beneath them, a stud on the rod and adapted to engage a stop on the side of the case when one of the brushes is engaged with a cam-wheel, a stop engaging the other brush when the same engages a cam-wheel, and an actuating connection between said rod and the sand-box, for the purpose specified.

14. The combination, in a sander, of a hinged sand-box, a case, a shaft in the case, a wheel on the center of said shaft, provided on its periphery with a series of cams having shoulders and sloping faces, wheels on said rod and at the sides of the center wheel and having cams similar to those thereon and set in an opposite direction, a revoluble reciprocating rod above the shaft, a rigid brush on the center of the rod and adapted to engage the cams of the center wheel, rigid side brushes set on said rod at an angle with the center brush and adapted to engage the cams on the side wheels, a stop on the rear wall of the case and bearing against the center brush when engaged with its cam-wheel, stops on the ends of the case, studs on said rod and adapted to engage the stops on the end of the case when the end

brushes are engaged with their cam-wheels, and an actuating connection between said rod and the sand-box, substantially as and for the purpose specified.

15. The combination, in a sander, of an inclined sand-box having a delivery-opening in the lower end, rocking arms toward the upper end of the sand-box and hinged on a support, wrist-pins on the sand-box between the rocking arms and the delivery-opening, a case below the sand-box, a shaft in the case, a wheel on the center of said shaft, provided on its periphery with a series of cams having shoulders and sloping faces, wheels on said shaft and at the sides of the center wheel and having cams similar to those thereon and set in an opposite direction, a revoluble reciprocating rod having its bearings in vertical slots in the end walls of the case, a rigid brush on the center of the rod and adapted to engage the cams of the center wheel, rigid side brushes on said rod at an angle with the center brush and adapted to engage the cams on the side wheels, a stop on the rear wall of the case and bearing against the center brush when engaged with its cam-wheel, stops on the ends of the case, studs on said rod and adapted to engage the stops on the end of the case when the end brushes are engaged with their cam-wheels, and rods connecting the ends of said revoluble reciprocating rod and said wrist-pins, substantially as and for the purpose specified.

16. The combination, in a sander, of an inclined sand-box having a delivery-opening in the lower end thereof, and teeth raised above the lower end of the delivery-opening and extending back across the same to the bottom of the sand-box and above the delivery-opening, the said teeth being broad and with narrow spaces between them back of said opening, and narrow and with wider spaces between them over said opening, for the purpose specified.

17. The combination, with a sander, of a sand-box having a delivery-opening, a series of bars extended across said opening, and a second series of bars located below the first series, the bars of the second series being located closer together than those of the first series, for the purpose specified.

18. The combination, in a sander, of an inclined sand-box having a delivery-opening in the lower end thereof, a series of teeth raised above the lower end of the delivery-opening and extending back across the same to the bottom of the sand-box and behind the delivery-opening, and a second series of teeth below the first series and set closer together than those of said first series, said lower series of teeth having their front ends adjacent to the front wall of the sand-box and their rear ends extending behind said delivery-opening, for the purpose specified.

19. The combination, in a sander, of an inclined sand-box having a delivery-opening in the lower end thereof, a series of teeth raised above the lower end of the delivery-opening and extending back across the same to the bottom of the sand-box and behind the delivery-opening, and a second series of teeth below the first series and set closer together than those of said first series, said lower series of teeth having their front ends adjacent to the front wall of the sand-box and their rear ends extending below the bottom of said sand-box behind said delivery-opening, for the purpose specified.

20. The combination, in a sander, of an inclined sand-box having a delivery-opening in the lower end thereof, a chute below the delivery-opening, a series of teeth having their shanks secured in a head, the head being raised above the lower end of the delivery-opening, said teeth extending back over the delivery-opening and having their rear ends resting on the bottom of the sand-box and above said delivery-opening, the teeth being broad and with narrow spaces between them back of said opening, and narrow and with wider spaces between them over said opening, and a second series of teeth below the first and having their front ends adjacent to the front wall of the sand-box and thence extending downward and backward through the opening and with their ends projecting behind said chute, the lower series of teeth being set closer together than the upper, substantially as and for the purpose specified.

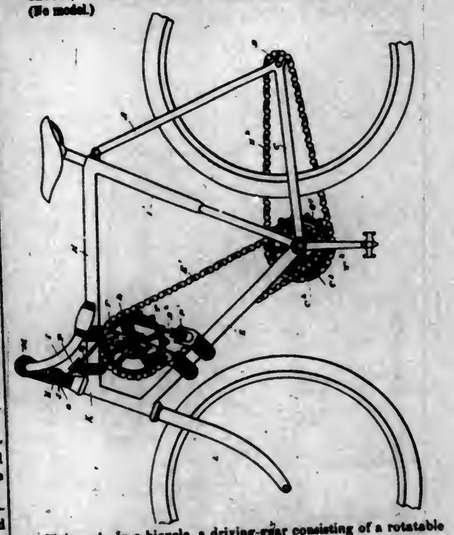
21. The combination, in a sander, of a sand-box, a hinged support for the sand-box, a support located on a side of the hinged support, a cushion interposed between said side support and the sand-box, and a device adapted to vibrate the sand-box about the hinge-support.

22. The combination, in a sander, of a sand-box, a hinged support for the sand-box, a resilient support on one side of the hinged support, and a device adapted to vibrate said sand-box about the hinged support.

23. The combination, in a sander, of a sand-box, a hinged support for the sand-box, a resilient support on one side of the hinged support, means for regulating the play of the resilient support, and a device adapted to vibrate said sand-box about the hinged support.

24. The combination, in a sander, of a sand-box, a hinged support for the sand-box on one side of the center thereof, a resilient support on the other side of said center, and a device connected with the sand-box between said supports and adapted to vibrate said sand-box about the hinged support.

25. The combination, in a sander, of a sand-box, a hinged support for the sand-box, a hollow cap attached to the sand-box on one side of the hinged support, a stationary base below the cap, a threaded adjusting-rod engaging a threaded opening through said base, the stem of said rod extending into the cap, a resilient connection between said stem and the cap, and means for vibrating the sand-box about its hinged support, for the purpose specified.



26. The combination, in a sander, of a sand-box, a hinged support for the sand-box, a hollow cap attached to the sand-box on one side of the hinged support, a stationary base below the cap, a threaded adjusting-rod engaging a threaded opening through said base, the stem of said rod extending into the cap, a resilient connection between said stem and the cap, an elastic sleeve around the stem of said rod and between the cap and base, and means for vibrating the sand-box about its hinged support, for the purpose specified.

27. The combination, in a sander, of a sand-box, a hinged support for the sand-box, a hollow cap attached to the sand-box on one side of the hinged support, a stationary base below the cap and having a socket in the top thereof, a threaded adjusting-rod engaging a threaded opening through said base, the upper end of said rod forming a shoulder in the socket in the base, the stem of the adjusting-rod extending into the cap and having a removable head thereon, a washer on said shoulder, an elastic sleeve embracing the stem of the adjusting-rod and having one end bearing on the bottom of the cap and the other end on said washer, a spring coiled around the stem of the rod and having its ends bearing on the head of the said stem and on the bottom of the cap, and means for vibrating the sand-box about its hinged support, substantially as and for the purpose specified.

28. The combination, in a sander, of a sand-box, a hinged support for the sand-box, a resilient support for said sand-box, mechanism for vibrating the sand-box about the hinged support, and a device for disconnecting the resilient support and thereby disengaging the vibrating mechanism, for the purpose specified.

29. The combination, in a sander, of a sand-box, a hinged support for the sand-box and adjacent to one end thereof, mechanism for vibrating said sand-box about the hinged support, a cap on the vibrating end of the sand-box and having a lug thereon, a stationary base below the cap and having jaws thereon, a resilient mechanism housed in said cap and base, and a cam-lever fulcrumed between the jaws and adapted to engage said lug and disconnect the resilient mechanism by raising said cap, substantially as and for the purpose specified.

605,559. HAND DRIVING-GEAR FOR CYCLES. WALTER TAYLOR, Brisbane, Queensland. Filed Apr. 12, 1897. Serial No. 631,239. (No model.)

Claim.—1. In a bicycle, a driving-gear consisting of a rotatable handle-bar, provided with a cam, a sprocket-wheel mounted on an independent frame between the forward reach-bars of the bicycle-frame and provided with rotatable toothed wheels mounted on either side of the said sprocket-wheel, duplicate quadrants mounted on the opposite sides of the said sprocket-wheel and provided with pawls to engage the said ratchet-wheels on the said sprocket-wheel, flexible attachments between the said quadrants and the cam on the handle-bar, a guide-pulley mounted on the frame of the bicycle to the side of the said quadrant removed from said handle-bar, a flexible connection between the two quadrants to pass under the said guide-pulley, and a flexible connection between the said sprocket-wheel and the crank-shaft of the bicycle, substantially as described.

2. In a bicycle, a driving-gear, consisting in the combination of the handle-bar, I, rotatably mounted in the head of the bicycle-frame, the elongated cam, M, mounted rigidly on the said handle-bar, guide-pulleys, N, N, sprocket-wheel, T, detachable frame, F, forming bearings for the wheel, T, ratchets, U, U', secured to the said sprocket, quadrants R, R', mounted on the shaft with the sprocket, T, and provided with pawls, A^4, A^4, to engage the said ratchet, flexible connections, Q, Q, attached to the said quadrants and connecting them with the cam, M, after passing under the pulleys, N, N, guide-pulley, P^7, mounted on the frame of the bicycle, flexible connection, B^9, passing under said guide-pulley and connecting the ends of the quadrants, R, R', sprocket-wheel, O', mounted on the crank-shaft of the bicycle, and sprocket-chain, E', connecting the sprocket-wheels, T and O', all substantially as described.

605,560. GAS-HEATER. MICHAEL ZIPPLER, Allegheny, Pa. Filed May 10, 1897. Serial No. 636,794. (No model.)

Claim.—1. In a gas-heater, the combination of a base or support, a mixing chamber thereon, a gas-supply for supplying gas to the mixing-chamber, a heating-chamber connected to the upper portion of the mixing-chamber, a cone-shaped resistance-plate within the mixing-chamber and provided with an opening therein, a spreader within the heating chamber adapted to direct the flame and products of combustion against the walls of the heating-chamber, and a deflecting-plate within the heating-chamber above the spreader, substantially as and for the purposes set forth.

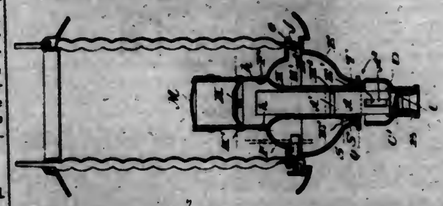
2. In a gas-heater, the combination of a base or support, a mixing-chamber thereon, a gas-supply pipe for supplying gas to the mixing-chamber, a heating-chamber connected to the upper portion of the mixing-chamber, a cone-shaped resistance-plate within the mixing-chamber provided with an opening therein, a gauze between the heating-chamber and resistance-plate, a concavo-convex spreader within the heating-chamber above the gauze having openings adjacent to its outer edge for the passage of the products of combustion through the same into the heating-chamber, and a deflecting-plate within the heating-chamber above the spreader having an opening therein for the escape of the waste products of combustion, substantially as and for the purposes set forth.

3. In a gas-heater, the combination of a base or support, a mixing-chamber thereon, a gas-supply pipe for supplying gas to the mixing-chamber, a heating-chamber connected to the upper portion of the mixing-chamber, a gauze between the heating-chamber and mixing-chamber, a concavo-convex spreader within the heating-chamber above the gauze and provided with openings adjacent to its outer edge for the passage of the products of combustion through the same into the heating chamber, and a deflecting-plate above the spreader and adapted to form spaces or openings between the upper surface of the same and the inner walls of the heating-chamber for the escape of the waste products of combustion, substantially as and for the purposes set forth.

605,561. CASH-RECEIVER. MANNERS ANDERSON, Chicago, Ill. Filed Feb. 20, 1897. Serial No. 624,423. (No model.)

Claim.—1. A cash-receiver comprising a cash-box receptacle, a chute connected therewith, said cash-box receptacle provided with a projecting part which engages the end of the cash-box, a partition extending across said cash-box receptacle, an opening through said partition, said partition and projection so positioned that the cash-box passes through the opening in the partition so as to enter the chute upon its side.

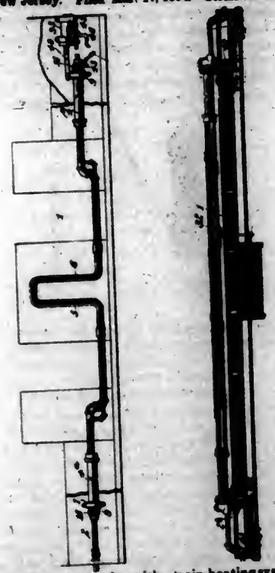
2. A cash-receiver comprising a cash-box receptacle, provided with a projecting part adapted to engage the end of the cash-box, an inclined partition extending across said cash-box receptacle and having an opening therethrough, said partition so positioned that the lower end of the cash-box enters said opening when the box engages said projection, said projection so positioned that the box is unbalanced when resting thereon, a chute below said cash-box receptacle, the whole so constructed that the cash-box is received in one position and delivered into the chute in another position.



3. A cash-receiver comprising a cash-box receptacle, a projecting part in said cash-box receptacle adapted to engage the end of the cash-box, a partition extending across said cash-box receptacle, and provided with an opening for said cash-box, a chute connected with said cash-box receptacle and provided with a discharge opening, said cash-box receptacle so constructed and positioned as to receive the cash-box endwise and discharge it sidewise into said chute whereby the first cash-box received in the first one to be delivered.

4. A cash-receiver comprising a cash-box receptacle, a projecting part on said cash-box receptacle adapted to engage the end of the cash-box, a partition extending across said cash-box receptacle and provided with an opening for said cash-box, said opening being enlarged at the ends so as to allow the enlarged ends of the box to pass therethrough, a platform beneath said cash-box receptacle, an opening opposite said platform, a chute connected with said opening and adapted to receive the cash-box, said chute provided at its lower end with an opening so that the cash-box may be removed therefrom.

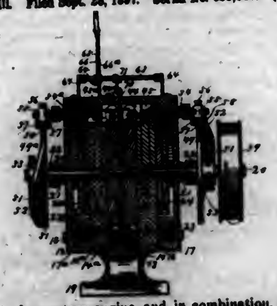
5. A cash-receiver comprising a cash-box receptacle, a projecting part on said cash-box receptacle adapted to engage the end of the cash-box, a partition extending across said cash-box receptacle and provided with an opening for said cash-box, said opening being enlarged at the ends so as to allow the enlarged ends of the box to pass therethrough, a platform beneath said cash-box receptacle, an opening opposite said platform, said opening enlarged at each end so as to allow the enlarged ends of the box to pass therethrough, a chute connected with said cash-box receptacle, and having a receiving end opposite said opening, the parts so constructed that the cash-box is received endwise into the cash-box receptacle and is then changed in position so as to enter the chute upon its side.



6. A cash-receiver provided with a receiving and a discharge opening, the receiving-opening constructed so as to receive the cash-box on end, a position-changing device for changing the position of the cash-box so that it arrives at the discharge-opening on its side, said position-changing device comprising an arresting or checking device between the receiving and discharge openings, and a receiving-platform upon which the cash-box is received before passing through said discharge-opening.

605,562. INCANDESCENT GAS-BURNER. JOHN W. BRADLEY, Watertown, N. Y., assignor to the Welsbach Lamp Company, same place. Filed Oct. 30, 1897. Serial No. 656,903. (No model.)

Claim.—An incandescent gas-burner, comprising in combination with the base, the burner-tube A and gas-tip C supported on a shoulder therein, the cup D with its lower flanged end upturned and fitted about said tube A, the cylindrical jacket B with beaded end, the disk Q thereon, means for supporting the jacket, and the mixing-chamber supported by the beads on said tube and jacket, as shown and described.



605,563. CAR-HEATING APPARATUS. ROBERT M. DIXON, East Orange, N. J., assignor to The Safety Car Heating and Lighting Company, of New Jersey. Filed Mar. 17, 1894. Serial No. 504,050. (No model.)

Claim.—1. The combination with a train-heating system, of drainage-tanks upon the cars thereof, means of communication between each of said drainage-tanks, and a single discharge-port for all of the tanks, of valves interposed between the drainage-tanks and their means of communication, adapted to shut off or establish drainage communication between the same, and mechanism for simultaneously operating each of said valves, substantially as set forth.

2. The combination with a train-heating system, of communicating drainage-tanks upon the cars of the system, and drainage-valves adapted to control the communication between the drainage-tanks, of a source of pneumatic energy, mechanism for pneumatically actuating the valves, and means of communication between the source of pneumatic energy and the pneumatic actuating mechanism, all substantially as set forth.

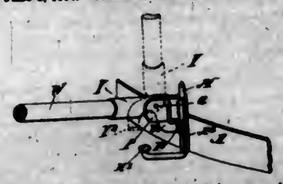
605,564. ROTARY STEAM-ENGINE. FREDERIC GALPIN, Willamsfield, Ill. Filed Sept. 28, 1897. Serial No. 653,267. (No model.)

Claim.—1. In a rotary engine, and in combination, a rotatable shaft, a wheel fixed to said shaft, a piston on the periphery of said wheel, an annular steam-chamber in which said piston revolves, a slidable abutment, a cylinder-head with twin steam-supply conduits for said piston, exhaust-conduits for said annular steam-chamber, a valve with steam-passages loosely mounted on said shaft, a valve fixed to said shaft and provided with a steam-passage, and a steam-chamber in which said valves are located, substantially as described.

2. In a rotary engine, and in combination, a rotatable shaft, a wheel fixed to said shaft, a piston on the periphery of said wheel, an annular steam-chamber in which said piston revolves, a cylinder-head with twin steam-supply conduits 30, 30ª therethrough for said piston, exhaust-conduits for said annular steam-chamber, valves 24 and 25, constructed and mounted substantially as described, and a steam-chamber in which said valves are located, substantially as described.

3. In a rotary engine, and in combination, a rotatable shaft, a wheel fixed to said shaft, a piston on the periphery of said wheel, an annular steam-chamber in which said piston revolves, a cylinder-head with steam-supply conduits 30, 30ª therethrough for said piston, exhaust-conduits for said annular steam-chamber, a valve loosely mounted on said shaft and having steam-passages 29, 29ª, means for adjusting said valve, a valve fixed to said shaft and having a steam-passage 27, a steam-chamber in which said valves are located, and a valved steam-supply pipe leading to said chamber.

4. In a rotary engine, and in combination, a rotatable shaft, twin wheels fixed to said shaft, a piston on the periphery of each of said wheels, twin annular steam-chambers in which said pistons revolve, slidable abutments, means for operating said abutments, twin cylinder-heads each having steam-supply conduits 30, 30ª, twin valves loosely mounted on said shaft, and each having steam-passages therethrough, means for simultaneously adjusting said valves, and twin valves fixed to said shaft and each having a steam-passage therethrough, substantially as described.



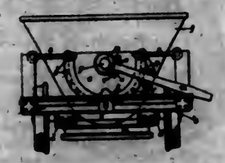
5. In a rotary engine, and in combination, a rotatable shaft, twin wheels fixed to said shaft, a piston on the periphery of each of said wheels, twin annular steam chambers or cylinders, slidable abutments, means for actuating said abutments, twin cylinder-heads each having steam-conduits 30, 30ª, twin pairs of valves, 24, 25, mounted on said shaft, a hand actuating-lever for said valves, means for operatively connecting said valves 25 with said lever, exhaust-ports at each side of said annular steam chambers or cylinders, exhaust-valves for said exhaust-ports and means for operatively connecting said exhaust-valves with said lever, whereby said valves 24, 25 and exhaust-valves are simultaneously adjusted, substantially as described.

6. In a rotary engine, and in combination, a cylinder provided with exhaust-ports, a rotary shaft, a cylinder-head having steam-supply conduits 30, 30ª, a valve adjustably mounted on said shaft and provided with steam-passages 29, 29ª, a valve fixed to said shaft and provided with a steam-passage 27, substantially as and for the purpose described.

7. In a rotary engine and in combination, a cylinder provided in its periphery with an exhaust-port, a valve therefor, a rotary piston, a cylinder-head having therein a steam-supply conduit, a valve therefor secured to the said shaft of said rotary piston, a second valve movable relative to said shaft, an operating-lever and connections for said second valve, and connections between said lever and said exhaust-valve whereby the valves are operated simultaneously, substantially as described.

8. In a rotary engine, and in combination, a cylinder having in the periphery thereof exhaust-ports, valves therefor, a rotary piston, a cylinder-head on one side of said rotary piston having steam-supply conduits therein, valves for said supply-conduits mounted on the shaft of said rotary piston, one fixed and the other loose thereon, a steam-chest surrounding said supply-valves, and means for operating said exhaust-valves and said loose valve, substantially as described.

605,565. TOWEL-RACK. JAMES W. LYON, Brooklyn, N. Y. Filed June 8, 1897. Serial No. 639,849. (No model.)



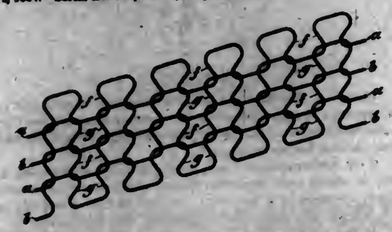
Claim.—1. In a towel-rack, a flexible strap A and adjustable connecting means, said strap being bent to present the vertical eyes A^2, upright pins bearing in the strap-eyes, a clip embracing each of the pins, and towel-supporting arms W, carried by said clips, substantially as herein specified.

2. In a towel-rack, the combination with the flexible strap A, presenting the vertical eyes A^2, of strap-connecting means, and upright pins M bearing in the strap-eyes, a clip embracing each of the pins M, and towel-supporting arms W, each pivoted to swing vertically in a clip, each arm having a heel or stop Y^2 to limit its downward movement, substantially as herein specified.

3. In a towel-rack, the flexible strap A, carrying the upright pins M, strap-connecting means, a clip P, for each pin and including a flat projection, in combination with a bar W having the thimble Y with flattened portion Y' pivoted on said projection to swing vertically, substantially as herein specified.

4. In a towel-rack, the flexible strap A carrying the upright pins M, strap-connecting means, a clip P, for each pin and including a flat projection, in combination with a bar W, having the thimble Y with flattened portion pivoted on each projection, and having an integral head or contacting part for limiting its downward movement, substantially as herein specified.

605,566. SLAG-TRUCK. JOHN H. MENZIES, Denver, Colo., assignor to the Colorado Iron Works Company, same place. Filed Jan. 7, 1898. Serial No. 665,911. (No model.)



Claim.—1. In a slag truck or car, a frame, a pot, projecting trunnions at each end, wheels or segments secured to said trunnions, transverse tracks supporting the said wheels, means for centering the pot and a lever for tilting the pot with means for engaging the lever with the wheel or segment, substantially as described.

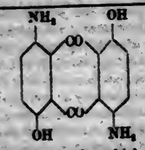
2. In a slag truck or car, a tilting pot, wheels or segments supporting the same, transverse tracks on which the segments roll and a lever having a pivotal connection at one end and reversible to tilt the car from one side or the other and having also provision for engaging one of the segments, substantially as described.

3. In a slag truck or car, a tilting pot, wheels or segments supporting the same, transverse tracks on which the segments roll, a lever pivoted in proximity to one of the segments to have movement transversely of said segment and a pawl carried by said lever adapted to engage ratchet-teeth on the segment, substantially as described.

605,567. FABRIC. Otto A. Mosse, New York, N. Y. Filed Aug. 4, 1897. Serial No. 647,031. (No specimens.)

Claim.—1. A fabric composed of wool and an absorbent material which are so disposed with respect to each other that both extend from one face of the fabric to the other and present a contacting surface on each face composed of separate portions of wool and of the absorbent material, substantially as described.

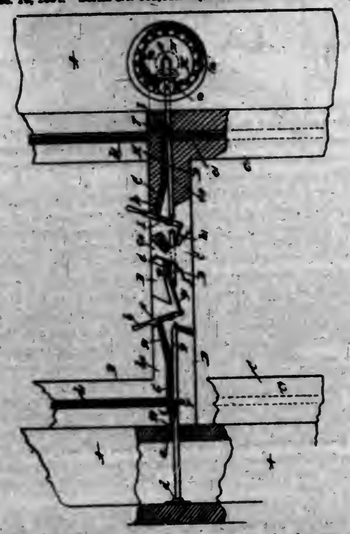
2. A fabric composed of wool and linen yarns which are so interlocked that both extend from one face of the fabric to the other and present a contacting surface on each face thereof that is composed of separate portions of wool and of linen, substantially as described.



3. A knitted fabric composed of wool and linen yarns which are so interknitted that both extend from one face of the fabric to the other and present a contacting surface on each face thereof that is composed of separate portions of wool and linen, substantially as described.

605,568. ANTHRAQUINONE DYE. ROBERT R. SCHMIDT, Elberfeld, Germany, assignor to the Farbenfabriken of Elberfeld Company, of New York. Filed Dec. 20, 1897. Serial No. 664,417. (No specimens.) Patented in Germany Dec. 20, 1893, No. 83,695; in England Jan. 16, 1894, No. 976; in France Jan. 20, 1894, No. 235,893, and May 17, 1897, No. 266,809, and in Italy Mar. 31, 1894, XXVIII, 36,093, LXX, 93, and June 30, 1897, XXXIII, 44,893, LXXXVII, 393.

Claim.—1. The production of paradiamideanthrarufin-monosulfo-acid by sulfonating paradiamideanthrarufin.



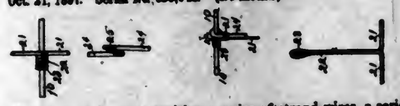
2. The process for producing a monosulfo-acid of paradiamideanthrarufin which process consists in sulfonating the said body by means of fuming sulfuric acid with the addition of boric acid, substantially as hereinbefore described.

3. As a new article of manufacture the new dyestuff, being a monosulfo-acid of paradiamideanthrarufin of the formula

and representing a blackish powder which when rubbed assumes a metallic luster, insoluble in alcohol, ether, benzene, nitrobenzene and in glacial acetic acid, soluble in anilin and pyridin with a pure greenish-blue color, in dilute alkalies with a blue color, yielding with concentrated sulfuric acid (66° Baumé) a yellow solution, which assumes a blue color on the addition of boric acid and shows in this state a characteristic absorption spectrum, dyeing unmordanted wool in acid-baths beautiful blue shades very fast to light, yielding on chrome mordanted wool greenish-blue shades very fast to light and milling.

605,569. WINDOW LOCK AND OPERATOR. ALBERT J. WILLIAMS, JOHN J. THOMAS, and MORGAN RICHARDS, Uniontown, Pa. Filed Dec. 16, 1897. Serial No. 662,112. (No model.)

Claim.—1. An improved window sash mechanism, comprising a rotary shaft arranged with respect to the sash and carrying gears, vertical rack-bars carried by the sash, and adapted to be engaged by said gears, the relative arrangement being such that said rack-bars terminate at a point beyond connection with the gears when the sash is in normal position, in combination with a slidable bar carried by the sash and provided with a rack-section adapted to be brought into connection with the gears upon the rotary shaft and into alinement with the vertical rack-bar upon the sash, and means for operating said bars carrying the rack-bar section, substantially as and for the purpose set forth.



2. An improved window-sash mechanism, comprising a rotary shaft arranged with respect to the sash and provided with gears, vertical rack-bars carried by the sash and adapted to be engaged by said gears, the relative arrangement being such that said rack-bars terminate at a point beyond engagement with the gears upon the rotary shaft when the sash is in normal position, bars slidably mounted in the end cross-bar of the sash-frame and carrying rack-sections adapted to be brought into connection with the gears upon the rotary shaft and into alinement with the vertical rack-bars upon the sash, and an operating-lever fulcrumed upon the sash and connected by pivotal connecting-bars with said slidable bars, substantially as and for the purpose set forth.

3. An improved window-sash hoist and lock mechanism, comprising a rotary shaft carrying gears, vertical rack-bars carried by the sash and adapted to be engaged by said gears, the relative arrangement being such that the vertical rack-bars terminate at a point beyond engagement with the gear upon the rotary shaft when the sash is in normal position, bars slidably mounted upon the sash and carrying rack-sections adapted to be brought into connection with

the gear upon the rotary shaft and into alinement with the vertical rack-bars upon the sash, and means for operating said slidable bars, in combination with the window-frame having recesses or holes, said slidable bars being extended so that they will engage said recesses or holes when their rack-sections are out of connection with the gear upon the rotary shaft, substantially as and for the purpose set forth.

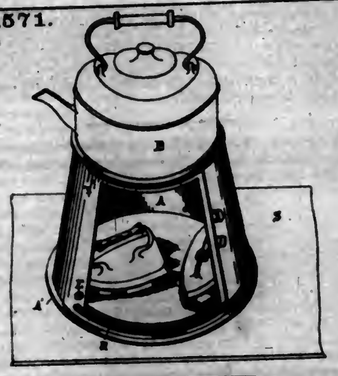
4. An improved window-sash mechanism, comprising a rotary shaft arranged with respect to the sash and provided with gears, vertical rack-bars carried by the sash and adapted to be engaged by said gears, the relative arrangement being such that said rack-bars terminate at a point beyond the gear upon the rotary shaft when the sash is in normal position, bars slidable upon the sash and carrying rack-sections adapted to be brought into engagement with the gear upon the rotary shaft and into alinement with the vertical rack-bars upon the sash, means for operating said slidable bars, an operating-shaft transversely arranged with relation to the rotary shaft and connected therewith, an actuating handle or device carried by said operating-shaft, and means for locking said operating-shaft in adjusted position, substantially as and for the purpose set forth.

605,570. FENCE. ENOS B. WILLIX, Mount Vernon, Iowa. Filed Oct. 21, 1897. Serial No. 655,942. (No model.)

Claim.—1. A fence comprising a series of strand-wires, a series of auxiliary stays each formed of a single length of rod and provided with a central circular loop, the body portions of the stay tangent to the loop being spaced apart, and means for connecting the end portions of the stay to the strand-wires.

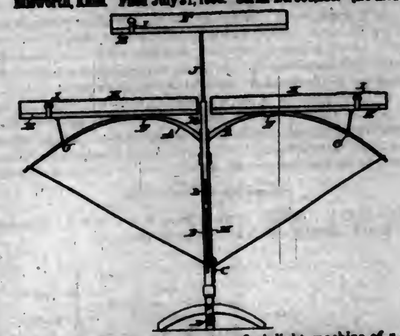
2. A fence comprising the following elements in combination, to wit, the strand-wires; a plurality of ordinary stays, each of which comprises a single length of wire offset at graduated distances of separation to form tongues 22, the side bars or members of the tongues being parallel throughout the major portions of their lengths and twisted at their extremities to form an elongated loop 23, the axis of which loop is at right angles to a plane tangential to the common points of contact of the side bars of the tongues, the portions of the sides between the tongues being overlapped at their ends and thereby positioned in parallel planes successively throughout the length of the stay; the end portions of the ordinary stays projecting beyond the outer strand-wires; auxiliary stays of less number than the ordinary stays and positioned parallel therewith; loops on the central portions of the auxiliary stays embracing one of the central strand-wires; loops on the ends of the auxiliary stays engaging the outer strand-wires; a means for connecting the auxiliary and ordinary stays, which means consists of bending the projecting end portions of the ordinary stays around the auxiliary stays and body portions of the ordinary stays, as set forth.

3. As a new article of manufacture, a fence-stay made of a single length of rod and formed with a single central loop, the body portions of the stay tangent to the central circular loop being spaced apart, the extremities of the stay being wound about strand-wires.



4. In a fence the combination of the strand-wires parallel with each other, auxiliary stays each formed with a central loop arranged and so shaped as to engage one of the central strand-wires and the end loops arranged and so shaped as to engage the outer strand-wires, and the stays 21 fixed to the strand-wires, a number of which stays 21 project at their ends beyond the marginal strand-wires, the remainder of which stays 21 have their end portions wound about the end portions of adjacent auxiliary stays and the body portions of the ordinary stays rigidly to connect the marginal strand-wires and the end portions of the auxiliary stays.

5. A fence comprising a series of strand-wires, a series of stay-wires arranged at right angles on the strand-wires and provided with a series of integral tongues, which tongues are wrapped upon the strand-wires, in combination with a series of auxiliary stays provided with central loops engaging one of the intermediate strand-wires and end loop engaging marginal strand-wires, the extremities of some of the ordinary stay-wires being wrapped upon and connecting the body portions of the ordinary stay-wires and the end portions of the auxiliary stays.



605,571. HEATING UTENSIL. JULIA H. ALEXANDER, Louisville, Ky. Filed Aug. 3, 1897. Serial No. 646,891. (No model.)

Claim.—The reversible heater, consisting of a frusto-conical metallic shell, open at top and bottom, and provided with a side door, whereby the heater is adapted for use with different-sized cooking utensils, and on a stove-top or on griddle-holes of different sizes, all substantially as described.

605,571.

605,572. AERIAL FLASH-LIGHT MACHINE. EDWARD C. BROWN, Ellsworth, Kans. Filed July 31, 1896. Serial No. 601,326. (No model.)

Claim.—1. The combination in a flash-light machine of a central support, and a plurality of elastic wooden arms supported thereby in mortises formed at an angle of about twenty-two and one-half degrees above a horizontal plane.

2. In combination in a flash-light machine, a central post, a plurality of elastic arms supported thereby and adapted to be simultaneously operated by a bow-cord attached to their free ends, and a lock, trigger, and check-wire cooperating with said bow-cord.

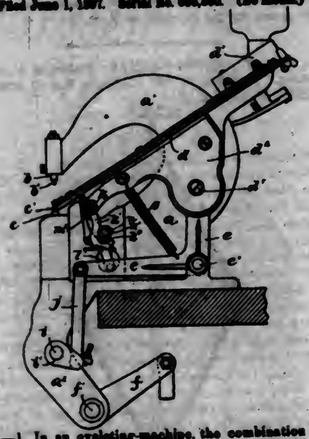
3. The combination in a flash-light machine, of a central post a plurality of elastic arms supported thereby, and simultaneously operated by a bow-cord attached to their free ends, and a powder-trough carried by each arm.

4. The combination in a flash-light machine of a powder-trough, a wire-netting supported above the trough, and means for violently throwing up the trough to force the powder through the netting.

5. The combination in a flash-light machine of a powder-trough, a wire-netting supported above the trough, lamps in said trough for heating the netting, and means for throwing up the trough, to force the powder through the netting, thereby igniting the powder.

6. The combination in a flash-light machine, of a post, a spring therein, a rod resting on said spring, a trough carried by said rod, a lamp in said trough, wire gauze placed above the lamp to be heated thereby, and means for operating the spring whereby the trough may be thrown up, forcing the powder through the heated netting.

605,578. BICYCLE-SUPPORT. JOSEPH S. CRAWFORD, New Kensington, Pa. Filed Sept. 23, 1897. Serial No. 652,346. (No model.)



Claim.—1. A bicycle-support comprising the base or rest, the standards extended upwardly therefrom having their upper ends

curved outwardly and upwardly, to form claws, said claws being provided with the bent ends to form hooks to enter openings of the pedal-arms, and an additional claw formed of a piece of wire having its lower portion secured to one of the standards, then coiled in an upward direction and around both standards and bent upwardly and outwardly and formed with a hook end, substantially as and for the purpose set forth.

2. A bicycle-support comprising the base or rest, the upwardly-extended standards formed integrally with said base and provided at their upper ends with the upwardly and outwardly curved portions to form the claws having the hooked ends, and an additional claw secured substantially as described to the upper portion of the support as and for the purpose set forth.

3. As a new article of manufacture, a bicycle-support made of spring-wire, the same comprising a base or rest, the standards upwardly extended from said base and formed integrally therewith, said standards at their upper ends being curved outwardly and upwardly to form the claws having the bent-over ends to serve as hooks to enter the openings of the pedal box or arms, and an additional claw formed of wire, the lower end of said wire being secured to one of the standards of the support and then coiled around both standards in an upward direction, the upper free end thereof branching out to form said additional claw, as and for the purpose set forth.

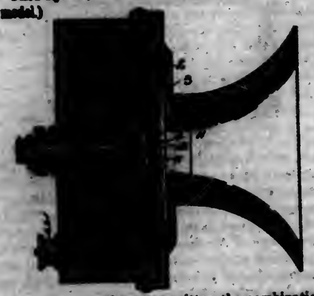
605,574. EYELETING-MACHINE. SETH W. FIELD, Quincy, Mass. Filed June 1, 1897. Serial No. 638,503. (No model.)

Claim.—1. In an eyeleting-machine, the combination with the eyelet-setting devices, the eyelet-chute, and mechanism for operating said parts, of means for guiding the chute horizontally and vertically and for preventing a rebound of the chute at the end of its forward movement.

2. In an eyeleting-machine, the combination with the eyelet-setting device, the eyelet-chute, and mechanism for operating said parts, of a guide for said chute to cause it to move horizontally forward and then vertically downward, and a lock for locking said chute at the end of its downward movement.

3. In an eyeleting-machine, the combination with the eyelet-setting device, the eyelet-chute, and mechanism for operating said parts, of a link for guiding said chute in its movements toward and from the eyelet-setting devices, and a lock for locking said chute at the forward end of its movement.

4. In an eyeleting-machine, the combination with the eyelet-setting device, the pivoted eyelet-chute, and mechanism for operating said parts, of a link connected to the chute and to an oscillating pivot for supporting and guiding the chute in its movements toward and from the eyelet-setting devices.



5. In an eyeleting-machine, the combination with the eyelet-setting devices, the eyelet-chute and mechanism for operating said parts, of a disk having a crank-pin and a link pivoted to the chute and to the crank-pin, said link supporting the lower end of the chute and guiding it in its movements toward and from the eyelet-setting devices.

6. In an eyeleting-machine, the combination with the eyelet-setting devices, the eyelet-chute and mechanism for operating said parts, of a disk having a stop and a crank-pin, a link pivoted to the chute and to the crank-pin, and a pawl for engaging the stop, and arranged to be operated by the chute for releasing it from engagement with the stop.

7. In an eyeleting-machine, the combination with the eyelet-setting devices, the eyelet-chute and mechanism for operating said parts, of a rotatable disk having a crank-pin, and a link connected to a pivot on the chute and to the crank-pin, and means for holding the parts with the axes of the disk, the crank-pin, and the pivot on a dead-center to lock the chute.

8. In an eyeleting-machine, the combination with the eyelet-setting devices, the eyelet-chute and mechanism for operating said parts, of a disk l having a stop l' and a crank-pin l^2, of a link l^3 pivoted to the chute and to the crank-pin and having a stop l^4, a pawl m having an arm m^2, and a stop or pin n', all cooperating for the purpose set forth.

605,575. CARBON TRANSMITTER. COURTNEY W. CRAN, Kahoma, Ind. Filed Apr. 30, 1897. Renewed Feb. 7, 1898. Serial No. 669,452. (No model.)

Claim.—1. In a carbon transmitter, the combination of a carbon-holder having a chamber to receive the powdered carbon, and an agitating device separate from the carbon-holder and arranged within the chamber thereof for agitating the powdered carbon in said chamber, independently of any movement of said carbon-holder, substantially as set forth.

2. In a carbon transmitter, the combination of a carbon-holder having a chamber to receive the powdered carbon, and a stirring device disassociated from said carbon-holder and arranged in said chamber to agitate the carbon therein without affecting the adjustment of the carbon-holder, substantially as set forth.

3. In a carbon transmitter, the combination of a carbon-holder having a chamber for the reception of powdered carbon, and a rotative stirring device disassociated from said carbon-holder and arranged in said chamber to agitate the powdered carbon therein without affecting the adjustment of said carbon-holder, substantially as set forth.

4. In a carbon transmitter, the combination of a carbon-holder having a chamber to receive the powdered carbon, a movable stem or spindle, and a stirring device carried on said stem or spindle and extending in said chamber, said stirring device being independent of the carbon-holder and arranged when the stem or spindle is moved to agitate the powdered carbon in the chamber without affecting the adjustment of said carbon-holder, substantially as set forth.

5. In a carbon transmitter, the combination of a carbon-holder having a chamber for the reception of powdered carbon, a rotatively-mounted stem or spindle, and a stirring device carried by the stem or spindle and arranged in the chamber, said stirring device being independent of the carbon-holder and adapted when the stem or spindle is turned to agitate the powdered carbon in said chamber without affecting the adjustment of said carbon-holder, substantially as set forth.

6. In a carbon transmitter, the combination of a carbon-holder having a chamber for the reception of powdered carbon, a sleeve carried by the carbon-holder and having one end adapted for communication with the chamber thereof, a stem or spindle movable in said sleeve, and a stirring device carried by the stem or spindle and extending in said chamber, said stirring device being arranged when the stem or spindle is moved to agitate the powdered carbon in said chamber, substantially as set forth.

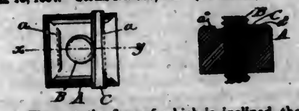
7. In a carbon transmitter, the combination of a carbon-holder having a chamber for the reception of powdered carbon, a sleeve connected electrically with the carbon-holder and having one end adapted for communication with the chamber thereof and its opposite end provided with a binding-post, a stem or spindle movable in the sleeve, and a stirring device carried on said stem or spindle and extending in said chamber, said stirring device being adapted when the stem or spindle is moved to agitate the powdered carbon in said chamber, substantially as set forth.

8. In a carbon transmitter, the combination of a carbon-holder having a chamber for the reception of powdered carbon, a sleeve con-

nected with the carbon-holder and having one end adapted for communication with the chamber thereof, a stem or spindle arranged to turn in said sleeve and having one end projecting beyond the rear end of the sleeve and provided with an enlargement by means of which it may be turned, and a stirring device carried on the opposite end of the stem or spindle and extending into the chamber in the carbon-holder, said stirring device being arranged, when the spindle or stem is turned, to agitate the carbon contained in said chamber, substantially as set forth.

605,576. DOOR FOR STEAM-BOILER FURNACES. FRANCIS L. HOSFORD, Ogden, Utah, assignor of one-half to Geo. J. Kelly, same place. Filed Sept. 23, 1897. Serial No. 652,717. (No model.)

Claim.—1. The combination in a steam-boiler furnace with the door-frame, of a door comprising an upper and a lower section, the lower section being hinged at its lower edge to the door-frame, and the upper section being hinged at its lower edge to the upper edge of the lower section, and bell-crank levers pivoted near the upper corners of the door-frame having their horizontal arms which pass along the upper edge of the door-frame arranged to move synchronously and provided at the lower end of their vertical arms with horizontal points adapted to project outside of and lock the lower section of the door, substantially as described.

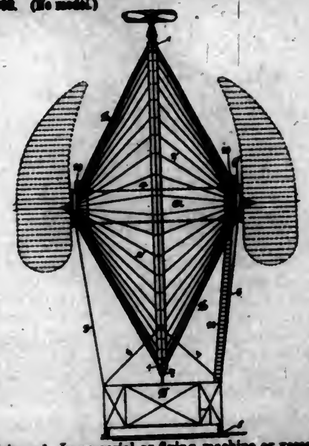


2. The combination of a steam-boiler furnace with the door-frame, of a door comprising an upper and a lower section, the lower section being hinged at its lower edge to the door-frame, and the upper section being hinged at its lower edge to the upper edge of the lower section, the lower section being provided with draft-openings, a slidable plate on the inside of said door-section for regulating said draft-openings, and a lever pivoted on the outside of the door and connected through the slot in the door with said slidable plate whereby the same is operated, substantially as described.

605,577. SAW. EDWIN H. HUTCHINSON, Jamestown, Ark. Filed Nov. 20, 1897. Serial No. 659,220. (No model.)

Claim.—An adjustable handle for saws consisting of a clamping-plate slotted to straddle the saw-blade and formed on its upper edge at its respective ends with ears, a cylindrical handle mounted between said ears through the medium of a pin passing therethrough, and clamping-screws carried by the plate, substantially as set forth.

605,578. NUT AND NUT-LOCK. HENRY A. HUDSON, Chicago, Ill. Filed Jan. 15, 1897. Serial No. 619,344. (No model.)



Claim.—1. The nut the face of which is inclined, the opposite inclined margins having ribs *a a* extending across the inclined face of the nut, and grooved or undercut in an acute angle on the sides of the ribs facing the center of the nut, substantially as described and for the purposes set forth.

2. The combination of a flat tapering key *c* with acute-angled edges beveled on the upper side; with a nut flat on its face, provided with marginal ribs *a a* on two opposite sides, undercut in correspondence with the bevel of key *c*, on the sides facing the center of the nut; and bolt B; the edges of the key on one side sliding in the grooves of the ribs, and on the other side cutting an angular recess obliquely across the thread of the bolt, and engaging the recess cut in the thread, locking the nut, the small end of key *c* bent down over the margin of the nut; all constructed, combined and operating substantially as described.

3. The combination of a flat tapering key *c*, with acute angled edges, beveled on the upper side, serrated; and a nut flat on its face, provided with marginal ribs *a a* on two opposite sides, undercut in correspondence with the bevel of key *c*, on the sides facing the center of the nut; and bolt B; the edges of the key on one side sliding in the grooves of the ribs and on the other side cutting an angular recess obliquely across the thread of the bolt and engaging the recess cut in the thread, locking the nut, the small end of key *c* bent down over the margin of the nut; all constructed, combined and operating substantially as described.

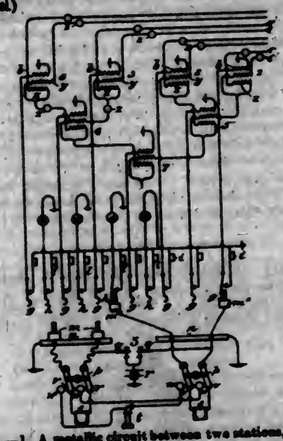
4. The combination of a flat tapering key *c*, with acute angular edges, beveled on the upper side; with a nut A, having its face inclined and provided with ribs *a a* on the inclined margins of the nut, undercut or grooved on the sides of the ribs facing the center of the nut, the angular section of the grooves corresponding with the bevel of the key *c*; and bolt B; the key *c* driven and cutting obliquely across the thread of the bolt, cutting an oblique recess across the thread of the bolt and engaging the recess so cut by the key, locking the nut, upon the bolt, the small end of key *c* bent down over the margin of the nut; all constructed, combined and operating substantially as and for the purposes set forth.

605,579. FLYING-MACHINE. FRIEDRICH A. JOSE, Dresden, Germany. Filed Mar. 18, 1897. Renewed May 17, 1898. Serial No. 680,992. (No model.)

Claim.—1. In an aerial or flying machine or vessel, the combination with the gas-container, of the lateral propelling mechanism located at the axial center of said container; substantially as described.

2. In an aerial or flying machine or vessel the combination with the lens-shaped gas-container, of the lateral propelling mechanism located at the axial center of said container; substantially as described.

3. An aerial or flying machine or vessel consisting of a lens-shaped gas-container, having a central tubular space for machinery, passengers and the like and for securing and operating lateral propelling mechanism and a rudder partially surrounding the circumference of the vessel substantially as described.



4. In an aerial or flying machine or vessel, of the character described, a framing surrounding the gas-container, constituted by an outer rim connected with the central tube by means of spokes and supporting the car by means of rods substantially as described.

5. In an aerial or flying machine or vessel, the combination with the gas-container, the central hub, the propelling wings adjustable relatively to the hub and mechanism for operating said wings; substantially as described.

6. In an aerial or flying machine or vessel, the combination with the gas-container, the central hub, the pivoted propelling-wings, the cross-beam attached to the wings, a shaft carried by the hub, cranks on said shaft, connecting-rods each connected at one end to the cross-beam and at the other to the cranks, a motor and gearing interposed between the motor and shaft; substantially as described.

7. In an aerial or flying machine or vessel, the combination with the gas-containers, the central hollow hub, an inner ring within the hub, the wings carried by said ring and means for rotating said ring to adjust the wings; substantially as described.

605,580. TELEPHONE CIRCUIT AND APPARATUS. MILO G. KELLOGG, Chicago, Ill., assignor to the Kellogg Switchboard and Supply Company, same place. Filed Mar. 23, 1897. Serial No. 628,093. (No model.)

Claim.—1. A metallic circuit between two stations, in which are included the secondary coils of two translators, one at each station, each translator containing a core and a primary coil and a secondary coil each wound around the core, each secondary coil having two parts and having its inductive center determined, and each point or portion of each part having a corresponding point or portion in the other part, which pairs of points or portions are equivalently in the same position with relation to every point or portion of the core, in combination with another circuit into which said metallic circuit is connected at the two inductive centers of said translators, transmitting apparatus sending varying currents through the two sides of said metallic circuit in series, and other transmitting apparatus sending at the same time varying currents through said other circuit into which said metallic circuit is connected.

2. A metallic circuit between two stations, in which are included the secondary coils of two translators, one at each station, each translator containing a core and a primary coil and a secondary coil each wound around the core, each secondary coil having two parts and having its inductive center determined, and each point or portion of each part having a corresponding point or portion in the other part, which pairs of points or portions are equivalently in the same position with relation to every point or portion of the core, in combination with another circuit into which said metallic circuit is connected at the two inductive centers of said translators, and rheostat apparatus in said metallic circuit whereby the resistances of the two derived circuits from one of said inductive centers to the other inductive center are made equal.

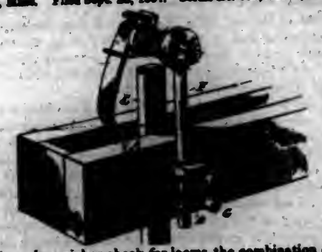
3. A metallic circuit between two stations, transmitting and receiving apparatus for respectively transmitting and receiving currents over said circuit, two coils, one at each station, included in said circuit, each coil comprising a core and wound around the core a coil with all its convolutions in the same direction and consisting of two parts, said two parts each having substantially an equal number of convolutions, and every convolution in one part having substantially its mate in the other part; which pairs of convolutions are equivalently in the same position and relation with reference to every portion of the core, in combination with another circuit into which said metallic circuit is connected at the two points, respectively, between said two parts of said coils.

4. A metallic circuit between two stations, transmitting and receiving apparatus for respectively transmitting and receiving currents over said circuit, two coils, one at each station, included in said circuit, each coil comprising a core and wound around the core a coil with all of its convolutions in the same direction, and consisting of two parts, said two parts each having substantially an equal number of convolutions and every convolution in one part having substantially its mate in the other part, which pairs of convolutions are equivalently in the same position and relation with reference to every portion of the core, in combination with another circuit into which said metallic circuit is connected at the two points, respectively, between said two parts of said coils, and rheostat apparatus in said metallic circuit whereby the resistance of the two derived circuits from one of said points to the other point are made equal.

5. A metallic circuit between two stations, in which are included the secondary coils of two translators, one at each station, each translator containing a core and a primary coil and a secondary coil each wound around the core, each secondary coil having two parts and having its inductive center determined, and each point or portion of each part having a corresponding point or portion in the other part, which pairs of points or portions are equivalently in the same position with relation to every point or portion of the core, in combination with another circuit into which said metallic circuit is connected at the two inductive centers of said translators, transmitting apparatus sending varying currents through the two sides of said metallic circuit in series, and other transmitting apparatus sending at the same time varying currents through said other circuit into which said metallic circuit is connected.

6. A metallic circuit between two stations, in which are included the secondary coils of two translators, one at each station, each translator containing a core and a primary coil and a secondary coil each wound around the core, each secondary coil having two parts and having its inductive center determined, and each point or portion of each part having a corresponding point or portion in the other part, which pairs of points or portions are equivalently in the same position with relation to every point or portion of the core, and the resistance of the two sides or branches of said metallic circuit from one of said inductive centers to the other inductive center being equal, in combination with another circuit into which said metallic circuit is connected at the two inductive centers of said translators, transmitting apparatus sending varying currents through the two sides of said metallic circuit in series, and other transmitting apparatus sending at the same time varying currents through said other circuit into which said metallic circuit is connected.

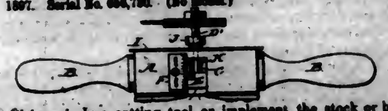
7. A metallic circuit between two stations, in which are included two coils, one at each station, each coil having a core and wound around the core a coil with all its convolutions in the same direction and consisting of two parts, said two parts each having substantially an equal number of convolutions, and every convolution in one part having substantially its mate in the other part, which pairs of convolutions are equivalently in the same position and relation with reference to every portion of the core, in combination with another circuit into which said metallic circuit is connected at the two points, respectively, between said two parts of said coils, and the resistance of the two sides or branches of said metallic circuit between said two points being equal, transmitting apparatus sending varying currents through the two sides of said metallic circuit in series, and other transmitting apparatus sending at the same time varying currents through said other circuit into which said metallic circuit is connected.



8. In a telephone system, two stations, a metallic circuit with balanced conductors between them in which are included the secondary coils of two translators, one translator at each station, each translator containing a core and a primary coil and a secondary coil each wound around the core, said secondary coil having two parts and said parts having substantially an equal number of convolutions and every convolution in one part having substantially its mate in the other part, which pairs of convolutions are equivalently in the same position and relation with reference to every portion of the core, in combination with another circuit into which said metallic circuit is connected at the two points, respectively, between said two parts of said secondary coils, subscribers' lines centering at each of said stations and switching apparatus at each station whereby the subscribers' lines centering there may at will be connected into the circuit of the primary of the induction-coil.

9. A metallic circuit between two stations, in which are included the secondary coils of two translators, one at each station, each translator containing a core and a primary coil and a secondary coil, each secondary coil having two inductive parts permanently fixed and determined, and each point or portion of each part having a corresponding point or portion in the other part, which pairs of points or portions are equivalently in the same position with relation to every point or portion of the core, and the resistances of the two sides or branches from a point between said two parts of the secondary of one coil to a point between said two parts of the secondary of the other coil being such and the coils being so constructed as to number of convolutions that when current passes in branch or derived circuit from one of said points to the other point, the inductive effect of the two parts of the secondaries connected into one of the derived circuits, balances and counteracts the inductive effect of the two other parts connected into the other derived circuit and no magnetic effect is produced in the core, in combination with another circuit into which said metallic circuit is connected at said two points between said parts of said secondary coils, transmitting apparatus sending changing current through said last-mentioned circuit and other transmitting apparatus sending at the same time telephone-currents over said metallic circuit.

10. A metallic circuit between two stations, in which are included



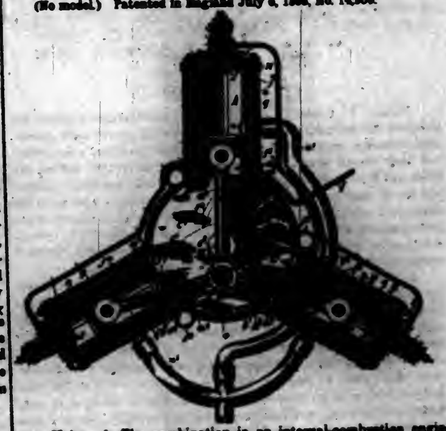
two coils, one at each station, each coil containing a core and wound around the core, a coil with all its convolutions in the same direction, said coil having two inductive parts permanently fixed and determined, and each point or portion of each part having a corresponding point or portion in the other part, which pairs of points or portions are equivalently in the same position with relation to every point or portion of the core, and the resistances of the two sides or branches from a point between said two parts of one coil and a point between said two parts of the other coil being such and the coils being so constructed as to number of convolutions that when current passes in branch or derived circuit from one of said points to the other point the inductive effect of the two parts of the two coils connected into one of the derived circuits balances and counteracts the inductive effect of the two other parts connected into the other derived circuit, and no magnetic effect is produced in the core, in combination with another circuit into which said metallic circuit is connected at said two points between said two parts of said two coils, transmitting apparatus sending changing current through said last-mentioned circuit and other transmitting apparatus sending at the same time telephone-currents over the two sides of said metallic circuit.

605,581. PICKER-CHECK FOR LOOMS. WILLIAM LOMBA, Fitchburg, Mass. Filed Sept. 23, 1897. Serial No. 652,725. (No model.)

Claim.—In a picker-check for looms, the combination of the lay of a loom, a bracket secured to the face of the lay and provided with a vertical bore, a vertical stem, adjustable longitudinally and rotatable in said bore and provided with a circular head on its upper end, having a concentric series of small horizontal openings, a plate located parallel to said head at a short distance therefrom, provided with a horizontal stem projecting beyond the plate, across the lay and through a central bore in the circular head, an arm projecting from the periphery of the plate, a curved latch pivoted upon the projecting end of the stem and having a lug adapted to engage the arm, and a spring coiled around the stem between the vertical head and plate, having one end engaging the outside of the latch and the other end engaged in one of the openings of the concentric series in the circular head, substantially as described.

605,582. CUTTING-TOOL. FRANCIS E. MERRIMAN, Boston, Mass., assignor to Herbert H. Kingsbury, Westfield, Mass. Filed Oct. 20, 1897. Serial No. 656,780. (No model.)

Claim.—1. In a cutting tool or implement, the stock or body having an opening made transversely through it, in combination with a block or gage adjustable in said opening, a knife or cutter beneath the block or gage, a screw, threaded in the stock or body and engaging the block or gage, and a plate or follower connected to and movable with the block or gage and engaged by the screw whereby the block or gage is adjusted with relation to the knife or cutter, and means for indicating the extent of said adjustment.



2. In a cutting tool or implement, the combination of the stock or body, a knife or cutter fitted thereto, a block or gage movable within the stock or body toward and from the knife or cutter, and means whereby the block or gage may be continuously moved during the cutting operation, consisting of a screw, threaded in the stock or body and engaging said block and a finger-piece for operating the screw.

3. The stock or body having a transverse opening, a block or gage adjustable in said opening and provided with upwardly-extending studs or guide-pins, a plate or follower fitted to the upper ends of the studs or pins exterior of the stock or body, a screw passing through a threaded opening in the stock or body and engaging said block or gage, for adjusting the latter, a knife or cutter beneath the block or gage and means for indicating the extent of movement of the block or gage.

4. The stock or body having the vertically-adjustable block or gage, a scale or series of graduations proximate to the block or gage, a screw and connections for adjusting the block or gage, a knife or cutter and means for securing it in place and means for determining the adjustment of the block or gage with reference to the knife or cutter, consisting of radial lines on the top of the stock and a pointer movable with the screw and adapted to be aligned with said lines.

5. A leather-cutting tool or implement comprising a handled stock or body having a transverse central recess and threaded top opening, a block or gage adjustable in said recess and provided with guide-pins or studs, extending through the top of the stock, a plate or follower connecting said pins or studs and having a central opening, a screw working in the threaded opening of the stock and passing loosely through the opening in the follower, and having a shoulder bearing under the latter, whereby the block is raised and lowered, a knife or cutter and means for securing it in position below the block or gage, a scale or series of graduations on the stock proximate to the block or gage, a plate on the top of the stock, having radial lines, and a finger-piece on the screw having a pointer to be moved over the radial lines, for indicating the relation of the block to the cutter.

605,583. INTERNAL-COMBUSTION ENGINE. FRANCIS L. MERRITT, London, England, assignor of three-eighths to Henry Arthur Naismith, Croydon, England. Filed Mar. 12, 1897. Serial No. 627,208. (No model.) Patented in England July 6, 1896, No. 14,959.

Claim.—1. The combination in an internal-combustion engine working on the two-stroke cycle specified of working cylinder, a combustible-supply port, a piston-valve therein normally held from closing the said supply-port, a valve-controlled supply-port to the working cylinder, a single valve J normally holding the said supply-port closed, a port through the said valve adapted to establish communication between the combustible-supply cylinder and the working cylinder when the single valve is off its seat, an air-supply to the working cylinder, a cam-tooth making one revolution for each two-stroke cycles of the engine and adapted by intermediate valve-gear to push the single supply-valve off its seat a little to make the piston-valve close the combustible-supply port, then to establish the above-mentioned communication between the combustible-supply cylinder and the working cylinder, to leave the supply-valve to be closed, and to leave the piston-valve to open the combustible-supply port.

2. The combination of a centrifugal governor on a crank-shaft arm, a fixed sleeve thereon, two inclosing cups fixed thereto, a double inclined block inclosed inside the said cups and protected by same to stop the block at each end of its transverse motion, a double inclined wedge-block mounted on a fixed sleeve and giving it motion connected to governor through the said cups by rods giving longitudinal motion and a cam on the double inclined block, a double inclined block inclosed between two cups and to a fixed sleeve having its longitudinal motion from the governor and transmitting the same to the cam which is also held between the edges of the said two cups to prevent a longitudinal motion to the said cam, a cam-block carried by and rotating with the crank-shaft and held by the said cups that each longitudinal motion of the wedge-block becomes a transverse one in the cam, an antifriction-roller and valve-gear transmitting the motion of the cam to the single supply-valve of the engine as described.

3. The combination of a centrifugal governor, a cam-tooth of variable projection under the action of the same, a valve-gear actuated by the said tooth, a valve controlling the only supply-port to the working cylinder adapted to be opened first by a given projection of the said tooth and a piston-valve controlling the combustible supply to an intermediate cylinder adapted to be opened only by a longer projection of the said tooth.

4. The combination of a compressor (consisting of radial arm, air-supply ports and blades) mounted on the engine-shaft and capable of being subdivided into as many subchambers as there are cylinders to the engine, with as many ducts therefrom as there are subdivisions, a radial arm mounted on the said shaft inside a surrounding shell of a compressor revolving concentric to the same, an air duct concentric to and in the axial line of the said shaft from the outside air to a series of air-ducts diverging outward from the said shaft and through the radial arm delivering its air into the compressor on the reverse side of the said arm's line of motion filling the vacuum caused by the forward motion, as many blades as there are subdivisions, each blade constructed to maintain a constant sliding contact with the radial arm, air-tight and to deliver its air to its own working cylinder through its own air-duct up to a supply-port and valve in each working cylinder, a casing suitably constructed according to the number of subdivisions, with recesses to receive the blades so that the radial arm may ride smoothly over them, and a return spring to maintain air-tight contact between the blades and the radial arm, a radial arm constructed of such a form that the blade may rise very quickly and deliver its air, the return motion being regulated by the outline of the said arm to produce a smooth action, the function of the compressor being to supply the engine with air for combustion and air-currents for the various operations of the engine when working, both such supply and currents being under pressure.

5. The combination in an internal-combustion engine working on the two-stroke cycle specified, of working cylinder, a constant and independent air-compressor, single valve controlling the only supply-port to the said cylinder, a piston-valve controlling the combustible-supply port to an intermediate chamber, a valve-gear actuated by a single-tooth cam and opening the only single supply-valve to the cylinder according to the projection of the said cam, and an automatic igniting device.

605,584. KEY-HOLDER. CLARENCE M. MOSELY, Howard, Pa. Filed Nov. 15, 1897. Serial No. 658,603. (No model.)

Claim.—The herein-described key-holder consisting essentially of the annular body or annulus A formed by bending a piece of wire into circular form with its ends connected together, and the plurality of snap-hooks B each formed by a single strip of resilient metal bent to form an eye at one end receiving the annular body or annulus A whereby they are permanently connected to the annular body and while held against endwise movement on said annular body are free to move entirely around upon the same, substantially as specified.

605,585. ROTARY ENGINE. WILLIS H. PHILLIPS, Wampum, Pa. Filed May 14, 1897. Serial No. 637,979. (No model.)

Claim.—1. In a rotary engine, the combination of a case having the inner sides of its heads formed with circular recesses, a cylinder located within the case and secured between the heads thereof with its bore eccentric to the recesses in the heads of the case, a piston concentric with the circular recesses in the heads of the case and eccentric with reference to the cylinder and having its end portions projecting beyond the cylinder into the recesses of the heads of the case, end rotary heads secured upon the shaft of the piston to revolve therewith and located in the aforesaid recesses and bearing against the ends of the cylinder, substantially as set forth.

2. In a rotary engine, the combination of a case having circular recesses formed in the inner sides of its heads, a cylinder located within the case and secured between the heads thereof and eccentrically disposed with reference to the said circular recesses, a piston concentric with the circular recesses and eccentric with respect to the cylinder and having its end portions projecting beyond the ends of the cylinder and entering the recesses formed in the heads of the case, and having a diametrical slot extending beyond the extremities of the cylinder, wings slidably mounted in the said diametrical slot, and rotary heads secured to the end portions of the piston-shaft and located in the afore described circular recesses with their inner faces abutting against the ends of the cylinder, and recessed to receive the projecting end portions of the piston and having radially-disposed grooves in which operate the end portions of the wings, substantially as set forth.

3. In a rotary engine, the combination of a case having circular recesses formed in the inner sides of its heads, a cylinder located within the case and secured between the heads thereof with its bore eccentric to the said circular recesses, a piston concentric with the said circular recesses and eccentric to the cylinder and having its end portions projecting beyond the ends of the cylinder into the recessed heads of the case, and having a diametrical slot, wings slidably mounted in the said diametrical slot, rotary heads mounted upon the end portions of the piston-shaft and located in the aforesaid circular recesses with their inner faces bearing against the ends of the cylinder and having their inner faces recessed to receive the projecting end portions of the piston and formed with radial grooves, and notches, the latter corresponding with similar notches in the projecting ends of the piston, and keys fitted in the notches of the rotary heads and piston to cause these parts to revolve in unison, substantially as set forth.

4. In a rotary engine, the combination with a cylinder, and a slotted hub, of a wing comprising side plates having their outer edge portions thickened on their inner sides, a rocker-bearing, a follower forming a seat for the rocker-bearing, and a spring exerting an outward pressure on the follower, substantially as set forth.

5. In a rotary engine, the combination with a cylinder, and a slotted hub, of a wing comprising side plates thickened on their inner faces at their outer edges, an intermediate strip between the thickened portions of the side plates, a rocker-bearing having seats to receive the inner edges of the thickened parts of the side plates and the inner edge of the intermediate strip, a follower, and a spring exerting an outward pressure on the follower, substantially as set forth.

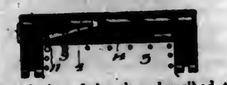
6. In a rotary engine, the combination with a cylinder, and a piston having a diametrical slot, of a strip movable laterally in the said slot and of a corresponding width thereto, packing-strips located in grooves in the sides of the said strip and bearing against the walls of the aforesaid slot, wings at opposite sides of the strip and bearing against the inner wall of the cylinder, and springs housed and protected by the wings and interposed between the latter and the aforesaid strip, substantially as set forth.

7. In a rotary engine, the combination with a cylinder, and a slotted hub, of a strip located and movable transversely within the slotted hub, wings upon opposite sides of the strip, each comprising side plates thickened at their outer edges on their inner sides, a strip intermediate of the thickened portions, a rocker-bearing provided with seats to receive the inner edges of the intermediate strip and thickened portions, a follower, and a spring interposed between the follower and a side of the strip, substantially as and for the purpose set forth.

605,586. STUMP-EXTRACTOR. GEORGE H. ROLLINS, Pittsville, Wis. Filed Nov. 13, 1896. Serial No. 612,092. (No model.)

Claim.—In a stump-extractor, the combination of the standards having runners at their lower ends, their upper ends being brought

together at a common center, of the cap-plate arranged upon the top of said standards, a short rod screw-threaded at its upper end and passing through said plate, a nut for holding said rod and adjusting it in said cap-plate, a supporting-rod loosely connected to the opposite end of said short rod, an operating-lever pivotally attached at its center to the lower end of the supporting-rod, the bearing-plates at the middle of said lever having notches arranged at each side of the supporting-rod, the power-box through which the supporting-rod extends, said box being freely movable vertically upon said rod and having a series of perforations arranged in longitudinal parallel rows, the removable lift-pins fitting in said perforations, the pulley-block M, the cross-piece N, chain L connected to the lower end of the power-box, passing around the block and having its opposite end attached to cross-piece N, and the chain O connecting the block with the stamp, substantially as shown and described.



605,587. FLEXIBLE METALLIC PIPE. CHARLES RUDOLPH and GEORGES LEVAVASSEUR, Paris, France. Filed Sept. 3, 1897. Serial No. 650,544. (No model.) Patented in France Aug. 3, 1896, No. 258,770.

Claim.—1. A flexible metallic pipe, comprising in its construction a metallic strip having an inwardly-facing groove and an outwardly-facing groove, the said inwardly and outwardly facing grooves being of considerable width, the metal of the strip being bent so as to form another groove upon the edge of the outwardly-facing groove, and adapted to receive a packing, said edge groove then formed having its bottom flush with the bottom of the said outwardly-facing wide groove, the construction being such that when the metal strip is wound upon itself to form the flexible pipe the narrow groove will be arranged interiorly of the said pipe and will permit of the pipe being bent or curved in any direction as well as extended or collapsed, substantially as described.

2. A flexible metallic pipe produced by spirally winding a metallic strip having inner and outer facing grooves, the metal of the said strip being shaped so as to form an edge groove upon the outwardly-facing groove, the said edge groove having its bottom upon the same plane with the bottom of the outwardly-facing groove, said groove containing a tight packing capable of sliding over the slightly-curved face of the adjacent spiral, the pressure of the spirals one against the other, resulting from their respective displacements, taking place between the metallic parts of each spiral, substantially as described.

605,588. MAIL-BAG FASTENER. CHARLES A. STRASBURG, Cridersville, Ohio. Filed Nov. 4, 1897. Serial No. 657,405. (No model.)

Claim.—1. In a device of the class described, the combination of a casing composed of two hinged sections, a rotary bolt or shaft journaled in the casing and provided with a lug arranged at an angle to it and adapted to engage the free edges of the sections to lock the same closed, and a spring-actuated tumbler engaging the bolt or shaft and holding the same against rotation in either direction, said tumbler being adapted to be disengaged from the shaft or bolt by a key, substantially as described.

2. In a device of the class described, the combination of a casing, a bolt or shaft journaled therein and provided with engaging lugs, said bolt or shaft having a polygonal portion, and a spring-actuated tumbler provided with a bifurcated arm straddling the polygonal portion of the shaft or bolt and locking the same against rotation in either direction, said tumbler being adapted to be engaged by a key, substantially as described.

3. In a device of the class described, the combination of a casing having a keyhole, a shaft or bolt journaled in the casing at one side of the keyhole and provided with lugs, said shaft or bolt having a rectangular portion adjacent to the said keyhole, a spring-actuated tumbler mounted in the casing at the opposite side of the keyhole and provided with an arm engaging the rectangular portion of the shaft or bolt, and a key adapted to be interposed between the tumbler and the shaft or bolt and provided with opposite lugs for engaging the same, one of the lugs being beveled and arranged to rotate the shaft or bolt, substantially as described.

4. In a device of the class described, the combination of a casing composed of two hinged sections, one of the sections being provided with a perforated flange, a bolt or shaft journaled on the other section, provided with an exteriorly-arranged handle and having a series of lugs for engaging the perforations of said flange, and a spring-actuated tumbler engaging the shaft or bolt and locking the same against rotation, substantially as described.

605,589. BURGLAR-ALARM. ALBERT V. TOOD, Colwich, Iowa. Filed Oct. 4, 1897. Serial No. 653,909. (No model.)

Claim.—1. In a combined burglar-alarm and door-fastener, a casing provided with a keeper-slot, a cartridge-socket out of line with said slot and an elevated rest-post adjacent to said socket, in combination with a spring-controlled bolt fitted in the casing to slide and turn therein, said bolt provided with an angular head adapted to fit in the keeper-slot and enable the foot of the bolt to be projected sufficiently beyond the casing to engage with the floor, and also adapted, when the bolt is turned in one direction, to engage with the rest-post and sustain the bolt in a raised position, and means to turn the bolt and move the striker-hammer on the bolt-head into alinement with the cartridge-socket, substantially as and for the purposes described.

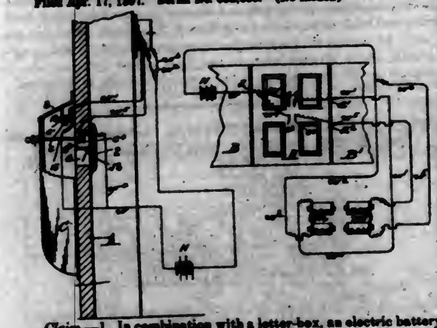
2. In a combined burglar-alarm and door-fastener, a casing provided in its head with a cartridge-socket, the parallel rest-post and guide-pin adjacent to said socket, and a longitudinal keeper-slot, combined with a spring-controlled bolt provided with an angular head and arranged to project below the casing, a friction-foot carried by the lower end of the bolt, and a striker-hammer carried by said head of the bolt, substantially as described for the purposes set forth.

3. In a combined burglar-alarm and door-fastener, a casing provided with an enlarged head, a central keeper-slot, cartridge-sockets in the head and on opposite sides of the keeper-slot, rest-posts adjacent to the cartridge-sockets and on opposite sides of said keeper-head, and guide pins or studs parallel to the rest-posts, in combination with a spring-controlled bolt fitted loosely in said casing to slide and turn therein and provided with an angular head adapted to project beyond either of said rest-posts when the bolt is raised for said head to engage with the rest-post, a striker-hammer carried by the bolt-head, and a detent in the path of said angular bolt-head, substantially as described for the purposes set forth.

4. The combination of a casing provided with a keeper-slot which extends below an enlarged head of said casing and with a cartridge-socket in said enlarged head, a spring-controlled bolt carrying at its upper end a striker-hammer, a friction-foot attached to the lower end of said bolt and an elevated rest-post supported by the casing at one side of the keeper-slot and adjacent to the cartridge-socket, whereby said bolt may be fitted in the keeper-slot and projected sufficiently beyond the casing for the friction-foot on said bolt to engage with the floor, or said bolt may be raised to engage with the rest-post and be held in position for the striker-hammer to enter the cartridge-socket, substantially as described for the purposes set forth.

605,590. WEATHER-STRIP. JOHN T. WARTH, Golden, Ill. Filed June 18, 1897. Serial No. 641,248. (No model.)

Claim.—In a weather-strip, the combination with a stationary section, having a securing-face by means of which it is attached to the door, an intermediate portion inclined outwardly and downwardly from the securing portion, a downwardly-extending stop member, a movable section having its inner end bent at an angle to form an attaching portion, hinges secured to the outer surface of the attaching portion, and to the under side of the intermediate portion of the stationary section, whereby said sections are hinged together, said attaching portion adapted to abut against the stop member when the door is open, a spring-rod having its end bent at an angle and extending in reverse directions, one of said angular ends being secured to the under side of the intermediate portion of the stationary section adjacent one end of the weather-strip, and the opposite angular end secured to the under side of the movable section adjacent the opposite end of the strip, of an angular stop-plate secured to the door-frame and adapted to be engaged by the movable section of the weather-strip, whereby said section is held in engagement with the door-sill when the door is closed, substantially as described.



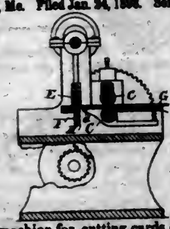
605,591. NON-REFILLABLE BOTTLE. WILLIAM G. WEBSTER, Grand River, Ohio. Filed Jan. 20, 1898. Serial No. 667,237. (No model.)

Claim.—1. A bottle provided with a neck, the outer portion of which is elliptical in cross-section, having a weakening-groove extending from the mouth along the neck, around one side thereof and back on the opposite side to the mouth, and a non-elastic, rigid plug, elliptical in cross-section, fitting in the elliptical portion of the neck, and means for turning the plug whereby the neck is broken at the weakening-groove, substantially as described.

2. A bottle provided with a neck, the outer portion of which is elliptical in cross-section, having a weakening-groove extending from the mouth along the neck, around one side thereof and back on the opposite side to the mouth, a non-elastic, rigid plug, elliptical in cross-section, fitting in the elliptical portion of the neck, provided in its outer end with a nick or groove to receive the blade of a screw-driver for the purpose of turning it, whereby the neck is broken at the weakening-groove, substantially as described.

605,592. LETTER-BOX. MILETUS J. WISE and CHARLES A. THOMPSON, Washington, D. C.; said Thompson assignor to said Wise. Filed Apr. 17, 1897. Serial No. 632,622. (No model.)

Claim.—1. In combination with a letter-box, an electric battery, a signal-box located adjacent to the letter-box, a signal in the signal-box, a hinged lid on the letter-box provided with an arm, a door on the letter-box provided with an arm, an electrical circuit, oppositely-disposed electromagnets in the circuit within the signal-box, a pivotally-supported armature to contact with the poles of the magnets and engage the signal with its free end to move the signal into and out of sight, and contacts in the circuit within the letter-box in the path of the arms on the lid and door thereof to make and break the circuit.



2. In combination with a letter-box, a lid on the letter-box provided with an arm, a door opening into the letter-box and provided with an arm, a signal-box, a signal in the signal-box, oppositely-disposed electromagnets mounted in the signal-box, a pivotally-hung armature between the poles of the magnets and formed with a sector-rack on its free end, a pinion on the shaft of the signal actuated by the armature, a battery, circuits from the battery to the magnets, and contacts in the circuits in the path respectively, of the arms on the letter-box lid and said door.

3. In a letter-box, a lid thereon provided with an arm, a door opening into the letter-box and provided with an arm, a source of electric energy, circuits therefrom made and broken through the agency of said arms respectively, a signal-box adjacent to the letter-box, oppositely-disposed electromagnets in the circuits within the signal-box, a pivotally-supported armature to contact with either magnet and provided with a sector-rack on its free end, a pinion journaled in the signal-box to mesh with said rack, and a signal on the pinion-shaft to be moved thereby.

4. The combination with a letter-box, and electrical circuits made and broken through the agency of movable parts of the letter-box, of a signal-box, electromagnets oppositely arranged in the signal-box and interposed in the circuits, a pivotally-hung armature between the poles of the magnets and formed with a sector-rack on its free end, a pinion journaled to mesh with the said rack, a signal on the pinion-shaft formed with an arm, and a lamp in the path of the arm whereby when the arm is moved down it covers the flame of the lamp and extinguishes it.

5. In a letter box and in combination with electrical circuits made and broken therefrom, a signal-box, oppositely-disposed electromagnets in the signal-box in said circuit, a pivotally-supported armature between the poles of the magnets and formed with a sector-rack on its free end, a pinion journaled to mesh with the said rack, an arm on the journal of the pinion formed with an inverted cup on its free end, and a lamp in the path of the cup.

605,598. MACHINE FOR MAKING MATCH-CARDS. SOLOMON W. BATES, Portland, Me. Filed Jan. 24, 1898. Serial No. 667,710. (No model.)

Claim.—1. In a machine for cutting cards of pointed matches from veneer strips, the combination of a cutting-block and a splitting-knife adapted to reciprocate, one with relation to the other, means for feeding the veneer strip between them and a V-shaped notching-knife set one or more spaces ahead of said splitting-knife and having the open end of the V turned outward, whereby the notches are cut with a single stroke of said knife.

2. In a machine for cutting cards of pointed matches from veneer strips, the combination of a cutting-block and a splitting-knife adapted to reciprocate, one with relation to the other, means for feeding the veneer strip between them, a V-shaped notching-knife set one or more spaces ahead of said splitting-knife and having the open end of the V turned outward and an ejector for knocking out from said V-shaped knife the triangular pieces cut by said knife at each reciprocation of the machine.

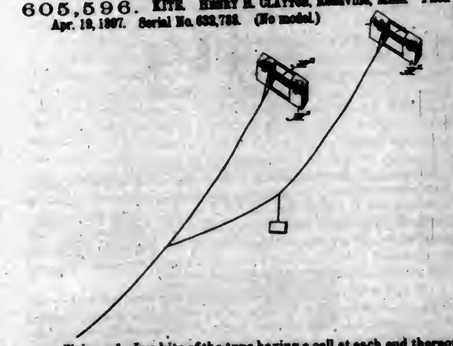
605,594. TELEPHONE-RECEIVER. PETER C. BUNN, Chicago, Ill. Filed Nov. 30, 1897. Serial No. 659,948. (No model.)

Claim.—1. In a telephone-receiver, a permanent magnet, a collar mounted thereon, a diaphragm-cap, a diaphragm and a cup-shaped member to which the diaphragm and cap are secured, and a screw connection between the cup-shaped member and the collar whereby the diaphragm may be adjusted in proper position relative to the pole-piece together with a disk on the collar and stop-screws in said disk adapted to bear against the cup-shaped member and lock the parts in adjusted position.

2. In a telephone-receiver, the combination with the permanent magnet and its accessories of the insulating-disk secured to the heel thereof and carrying the binding-screws, the insulating-sleeve bored lengthwise to slip over said disk, the collar upon which said sleeve

screws, and the adjusting-ring also screwing upon said collar and adapted to slip over said disk, and the diaphragm and diaphragm-cap.

3. In a telephone-receiver the combination with the permanent magnet and its accessories of the insulating-disk secured to the heel thereof, the sleeve adapted to slip over said disk, the screw-threaded collar, the adjusting-ring, the stop-screws, the diaphragm and the diaphragm-cap.



605,595. WIRE FENCE. P FRANK CLARKIN, Pontiac, Mich. Filed Mar. 7, 1898. Serial No. 673,240. (No model.)

Claim.—1. In a wire fence, the combination with the fence-wires of the picket formed of a vertical tie-wire, and a series of short strands twisted thereon, such twisted portion extending from one fence-wire to the adjacent fence-wire and the ends extending upon opposite sides of the picket forming portions which may be twisted about the fence-wires to secure the stay thereto.

2. In a wire fence, the combination with the fence-wires, of a picket formed of a single vertical tie-wire having its upper end bent upon itself and intertwisted, and a projecting end beyond the twisted portion, and a series of binding-wires on the tie-wire, extending the whole length thereof, each binding-wire being intertwisted a distance corresponding to the space between the adjoining fence-wires and having its ends extending out on opposite sides of the tie-wire to form means for binding the stay upon the fence-wires, substantially as described.

605,596. KITE. HENRY H. CLAYTON, Readville, Mass. Filed Apr. 19, 1897. Serial No. 633,788. (No model.)

Claim.—1. In a kite of the type having a cell at each end thereof, a frame comprising a corner-post at each corner of said cells, each of said posts extending lengthwise of the kite from end to end thereof, and braces connected with and to maintain said corner-posts rigid, substantially as described.

2. A kite having cells at its opposite ends, said cells being supported by a frame including corner-posts one for each corner of the cells, said posts extending from end to end of the kite, and struts or braces separating said posts and holding the kite rigid, said struts or braces being removably connected to said posts at their respective ends, whereby a knockdown kite-frame is provided so that the kite may be readily and quickly folded together in small compass or stretched out into operative position at will, substantially as described.

3. In a multicellular kite, the cells, and a supporting-frame therefor including corner-posts extending the whole length of the frame, and lateral bracing extended between and connecting the corner-posts to maintain the frame in rigid position, said bracing being located in substantially parallel planes and within the cells.

4. The combination, with a rectangular kite-frame having corner-posts extending the whole length of the kite, and braces for the corner-posts, said braces being located at opposite sides of the longitudinal center of the frame, of material stretched around the corner-posts at the ends of the frame to constitute cells, the forward edges of said cells being reinforced to present yielding cutting edges to the wind.

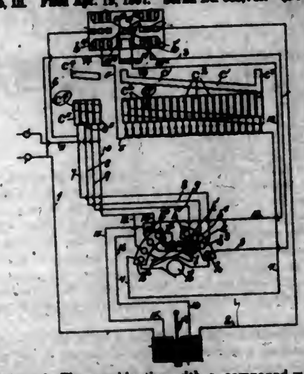
5. The combination with a rectangular kite-frame having corner-posts extending from end to end of the kite, and braces extending between said corner-posts to maintain said frame in proper rectangular position, said braces being slightly resilient and provided at their meeting portions with interlocking joints whereby they may be sprung into fixed relation with each other or may be separated therefrom at will, of material attached to the corner-posts at the ends of the frame to constitute cells, substantially as described.

6. In a multicellular kite, a quadrilateral frame including corner-posts extending the whole length of the kite, cross-bars connecting and rigidly spacing apart oppositely-located pairs of said posts, braces rigidly connecting the said cross-bars, and material attached to the corner-posts at the ends of said quadrilateral frame, to constitute the cells, the braces lying in substantially parallel planes located midway of the depths of the cells respectively.

7. In a kite having an open-ended, angular cell at each end thereof, a frame to support said cells, comprising a corner-post for each longitudinal corner of the kite, said posts extending the whole length of the kite from cell to cell, and braces to keep said corner-posts apart, the meeting portions of said braces and posts having cooperating interlocking joints and means for detachably securing them together, substantially as described.

8. In a multicellular kite, the cells, a plurality of longitudinal members at the corners of and extending from end to end of the kite, to prevent relative movement of the cells and catching of the flying-line between them, and a flying-line connected to the kite by a transverse loop extending from adjacent corner members to the said flying-line, substantially as described.

605,597. SAW-FRAME. GEORGE R. CLEMENTS, Rock Creek, Minn. Filed Aug. 24, 1897. Serial No. 649,268. (No model.)



Claim.—1. As an improved article of manufacture, a saw-frame consisting of a grip, curved spring-arms independent of said grip and having their adjacent ends secured to the ends of the grip and their other ends slotted to engage over the edge of a saw, and means movably mounted on one of said arms for detachably connecting said slotted ends to the ends of a saw, as set forth.

2. As an improved article of manufacture, a saw-frame consisting of a grip, curved spring-arms independent of the grip and having their adjacent ends secured to the ends of the grip and their other ends slotted to engage over the edge of a saw, and a latch pivoted on the outer end of one of said arms to engage an opening in the saw, the other arm being frictionally held upon the saw, substantially as specified.

3. The combination with a saw having an upright handle at one end and openings near the upper edge at the opposite end, of a saw-frame consisting of a grip with ferrules at its ends, curved spring-arms independent of the grip and secured to opposite ends thereof, the outer ends of the arms being slotted, the slotted end of one arm being frictionally held against the securing device of the said upright handle, and a pivoted latch on the outer end of the other arm to engage one of the openings in the saw, substantially as described.

605,598. ELECTRIC ELEVATOR. HAYWARD COGSWELL, Chicago, Ill. Filed Apr. 19, 1897. Serial No. 633,769. (No model.)

Claim.—1. The combination with a compound-wound electric motor, of a starting resistance for the armature-circuit, and a switch for successively short-circuiting the series-field coils to cut the same out of circuit, and means for first cutting the resistance from the armature-circuit in starting and then successively short-circuiting the series-field coils and for successively removing the short circuits around said series-field coils in stopping and then cutting resistance into the armature-circuit, substantially as described.

2. The combination with a compound-wound electric motor, of a starting resistance for the armature-circuit, and switch for successively cutting the series-field coils into and out of circuit a resistance adapted to be cut into and out of the shunt-field circuit and means for cutting the resistance from the shunt-field circuit in starting then cutting the resistance from the armature-circuit and cutting out the series-field coils and for cutting in the series-field coils in stopping, cutting the resistance into the armature-circuit and including the resistance in the shunt-field circuit, substantially as described.

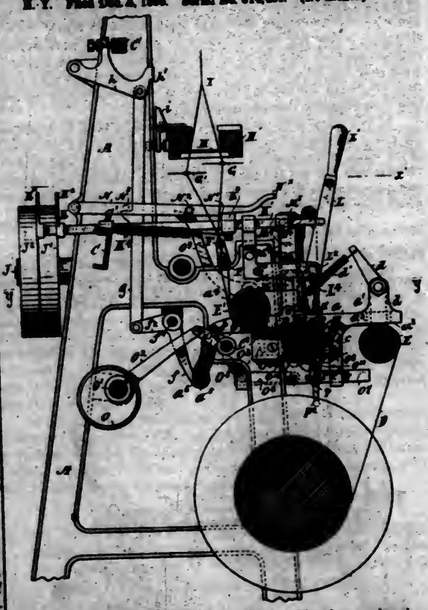
3. The combination with a series of brushes or contacts between which the coils of the armature-resistance are connected, of a series of brushes or contacts between which the series-field coils of an electric motor are connected, an oblique contact-bar making continuous contact with the end rheostat-brush and moving laterally to successively make and break contact with the brushes and a second oblique contact-bar adapted to make contact with the brushes connected with the series-field coils to cut the same into and out of circuit, substantially as described.

4. In a reversing-switch, the combination with a roller carrying at each end a pair of electrically-connected contact-plates, of two groups of three brushes each, one brush of each group being connected with the opposite side of the current-supplying circuit, the second brush of each group being connected with one side of the supplied circuit and the third brush of each group being connected with the opposite side of the supplied circuit, and means for moving the contact-plates into contact with the two brushes of the supply-circuit and the contact-plate at one end into contact with a brush of one side of the supplied circuit and the contact-plate at the other end into contact with a brush of the opposite side of the supplied circuit, substantially as described.

5. The combination with an electric motor, of a brake therefor, an armature or solenoid core connected with the operating-lever of said brake, and arranged to lift the brake-shoes, a stationary coil acting upon said core and included in series with the armature of said motor and a second stationary coil acting upon said core and included in shunt with the armature of the motor, substantially as described.

6. The combination with a compound electric motor, of a brake therefor, a brake-magnet provided with two coils, one in series with the armature and the other in shunt therewith, and switching apparatus for cutting the starting-resistance into and out of the armature-circuit and for cutting the series-field coils into and out of circuit, substantially as described.

7. The combination with a compound electric motor, of a brake therefor, a brake-magnet provided with a series and a shunt-winding, and switching apparatus for cutting the starting-resistance into and out of the armature-circuit for cutting the series-field coils into and out of circuit, and for cutting a resistance into and out of the shunt-field circuit, substantially as described.



605,599. AUTOMATIC RAILWAY-SWITCH. JOSEPH DELLER, Hopetown, Ind. Filed Mar. 19, 1898. Serial No. 674,394. (No model.)

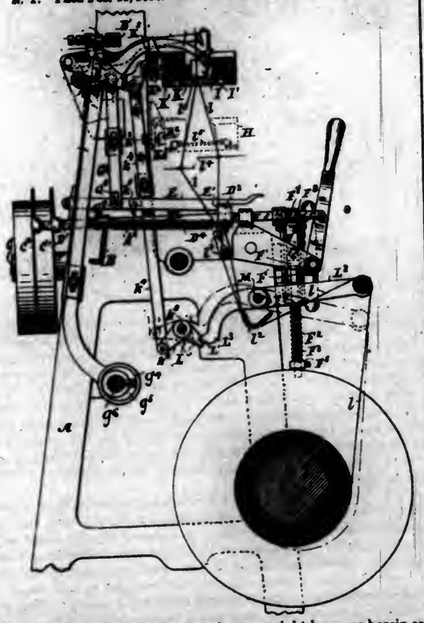
Claim.—1. A switch mechanism including a main shaft provided with starter and tread-plates, and a counter-shaft geared to said main shaft and coupled to the switch proper, said starter-plate being adapted to be operated by a car-trip, substantially as herein described, and for the purpose stated.

2. A switch mechanism including a main shaft G, provided with a tread-plate M, and starter-plate I, notched at *i*, *i'*, a mortised and longitudinally-grooved third rail H A *h'*, within which mortise A, said plate I *i* *i'* is fitted, a flap J that covers this plate, a counter shaft D *d*, a rod *e* that couples said shaft to the switch O, a spring L for retaining said flap in its closed position, and bevel-gears F, E, for communicating motion from said main shaft to said counter-shaft, all as herein described, and for the purpose stated.

605,600. WARP STOP-MOTION FOR LOOMS. ADRIAN D. HENRY, Taunton, Mass., assignor to the Universal Loom Company, New York, N. Y. Filed Dec. 4, 1896. Serial No. 614,621. (No model.)

Claim.—1. In an upright loom, the combination as herein set forth, of a progressively-acting stopping instrumentality adapted to bring the operative parts of the loom to rest by its progressive action during a prescribed part of one revolution of the lay driving shaft; a master trip-lever for normally holding said stopping instrumentality out of action; a warp stop-motion adapted to be, by the breaking of a warp-thread, rendered operative for tripping said master trip-lever, and so timed as to perform said tripping function at such predetermined stage in the revolution of the lay-driving shaft as will result in stopping the loom with the shed closed whenever a warp-thread breaks.

2. In an upright loom, a warp stop-motion comprising the following devices; warp-guides for guiding a section of warp through an approximately horizontal plane; a system of pins suspended upon the threads of said section of warp; a horizontally-sliding frame arranged beneath said system of pins; guides for guiding said pins in vertical paths; a horizontal rock-shaft mounted on said frame; a feeler-blade affixed to and projecting upwardly from said rock-shaft; connections between said frame and a constantly moving part of the loom, whereby said frame is constantly vibrated when the loom is in operation; a weighted dog pivotally mounted upon said frame and having its weighted end adapted to engage a radius-arm affixed to said feeler-blade rock-shaft, whereby by such engagement said feeler-blade is held in an upright position and said dog is held in an inoperative position; a progressively-acting stopping instrumentality and connections therewith projecting into the operative path of motion of said dog, as and for the purposes set forth.



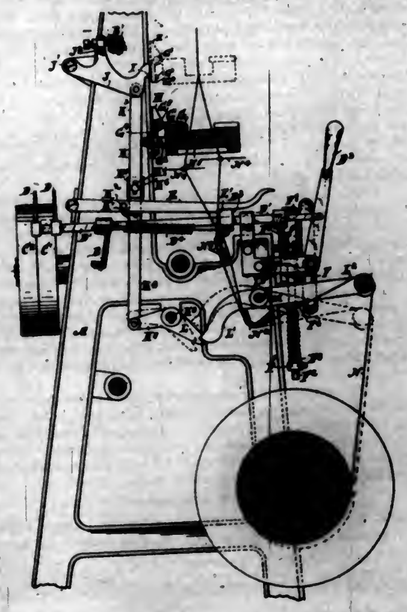
3. In an upright loom, mechanism for automatically stopping the loom with the shed closed whenever a warp-thread breaks, comprising essentially a group of pins suspended upon a section of warp occupying an approximately horizontal plane; a horizontally-sliding constantly-reciprocating frame arranged beneath said system of pins; a dog pivotally mounted upon said frame and partaking of the reciprocating motions thereof; means carried by said frame for normally holding said dog in inoperative position, said means embracing an upright feeler-blade traversing a path adapting it to be carried into collision with any warp stop-pin which by the breaking of the warp-thread on which it was suspended has been permitted to fall below its normal position; a progressively-stopping instrumentality and connections therewith projecting into the operative path of motion of said dog, as and for the purposes set forth.

4. In an upright loom, the combination, as herein set forth, of guides for maintaining a section of warp in an approximately horizontal plane; a series of stop-pins provided at their upper ends with return-bends and suspended upon the threads of said approximately

horizontal section of warp; guides for said pins, the same consisting of parallel vertical slots extending through a guide-board arranged beneath said section of warp and adapted to receive the longer legs of the said stop-pins, and parallel vertical grooves in the top of said guide-board for receiving the return bends or shorter legs of the said stop-pins; a stopping instrumentality for stopping the loom, and connections between said stopping instrumentality and said system of warp stop-pins, whereby if a warp-thread breaks the stop-pin originally suspended thereon by dropping from its normal position throws said loom-stopping instrumentality into action.

5. In a warp stop mechanism, substantially such as described, the group of return-bend pins, R, severally supported by the threads of the warp, in combination with the guide-bar, Q, provided with the vertical slots, Q^4, and the parallel grooves, Q^5, whereby the bights of said pins are made to extend diagonally across the warp-threads upon which they are respectively supported.

605,601. WEFT STOP-MOTION FOR LOOMS. ABRAM D. EMERY, Taunton, Mass., assignor to the Universal Loom Company, New York, N. Y. Filed Feb. 18, 1897. Serial No. 624,113. (No model.)

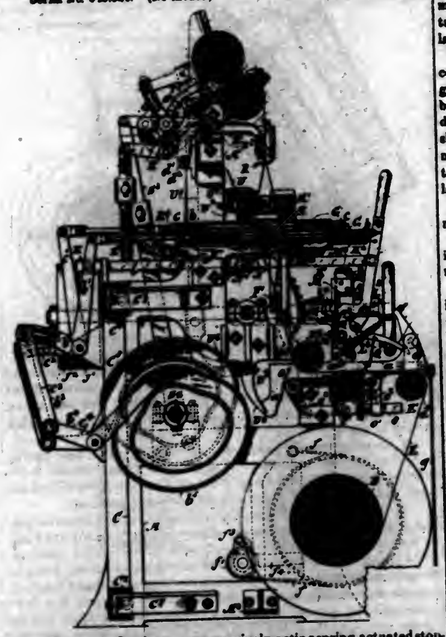


Claim.—1. The combination, in an upright loom, as herein set forth, of a spring-actuated progressively-acting stopping instrumentality, adapted to bring the operative parts of the loom to rest by its progressive action during a prescribed part of one revolution of the lay-driving shaft; a trip-lever for normally holding said stopping instrumentality out of action; a weft-fork and connections between said weft-fork and said stopping instrumentality, whereby if the weft-thread breaks or runs out the loom will be stopped with the lay down and the shed open.

2. The combination, in an upright loom, of a spring-actuated progressively-acting stopping instrumentality, adapted to stop the loom by its progressive action during a prescribed part of one revolution of the lay-driving shaft; a trip-lever for normally holding said stopping instrumentality out of action; a weft-fork and connections between said weft-fork and said trip-lever, whereby if a weft-thread breaks or runs out said trip-lever will be tripped at the conclusion of one beat of the lay, and the loom brought to rest before the lay can make another beat.

3. In an upright loom, the combination, as herein set forth, of a spring-actuated progressively-acting stopping instrumentality adapted to stop the loom by its progressive action during a prescribed part of one revolution of the lay-driving shaft; a trip-lever for normally holding said stopping instrumentality out of action; a weft-fork-carrying lever; a constantly-vibrating lever arranged in proximity to said weft-fork-carrying lever; a weft-fork pivotally mounted upon the free end of said weft-fork-carrying lever, and adapted to connect said weft-fork-carrying lever with said constantly-vibrating lever during the latter part of the beating motion of the lay if the weft-thread has run out or been broken; connections between said weft-fork-carrying lever and said trip-lever; a weighted detent adapted to engage a ratchet-wheel connected to the take-up roller for preventing said take-up roller from turning backwardly while the loom is in normal operation, and connections between said weft-fork-carrying lever and said detent, whereby the breaking or running out of the weft-thread effects the instant disengagement of said detent from said ratchet-wheel, and concurrently trips into action the said progressively-acting stopping instrumentality.

4. The combination, in an upright loom, as herein set forth, of a spring-actuated progressively-acting stopping instrumentality adapted to bring the operative parts of the loom to rest by its progressive action during a prescribed part of one revolution of the lay-driving shaft; a weft-fork arranged at one side of the warp and connections between said weft-fork and said stopping instrumentality, whereby if a weft-thread breaks or runs out the loom will be stopped with the shuttle in the box adjacent to the side of the warp opposite that where the weft-fork is arranged.



605,602. SHUTTLE STOP-MOTION FOR LOOMS. ABRAM D. EMERY, Taunton, Mass., assignor to the Universal Loom Company, New York, N. Y. Filed Feb. 20, 1897. Serial No. 624,264. (No model.)

Claim.—1. In a loom, the combination, as herein set forth, of a progressively-acting stopping instrumentality adapted to stop the loom by its progressive action during a prescribed part of one revolution of the lay-driving shaft; a shuttle stop-motion adapted to be brought into operation during the latter part of the beating-stroke of the lay, warp-slacking mechanism controlled by the said shuttle stop-motion, and connections between said shuttle stop-motion and said progressively-acting stopping instrumentality, whereby, if the shuttle fails to box properly, the operative parts of the loom are brought to rest just after the lay has commenced to recede from the beating-line.

2. In a loom, the combination, as herein set forth, of a progressively-acting stopping instrumentality adapted to stop the loom by its progressive action during a prescribed part of one revolution of the lay-driving shaft; a shuttle stop-motion adapted to be brought into operation during the latter part of the beating-stroke of the lay; a whip-roller for normally holding the warp under suitable tension; connections between said whip-roller and said shuttle stop-motion and connections between said shuttle stop-motion and said progressively-acting stopping instrumentality, whereby, if the shuttle fails to box properly, the warp is slacked and the operative parts of the loom are brought to rest just after the lay has commenced to recede from the beating-line.

605,603. LOOM. ABRAM D. EMERY, Taunton, Mass., assignor to the Universal Loom Company, New York, N. Y. Filed July 3, 1897. Serial No. 643,320. (No model.)

Claim.—1. In a loom, a progressively-acting spring-actuated stopping instrumentality adapted to bring the operating parts of the loom to rest by its progressive action during a prescribed part of a single revolution of the lay-driving shaft, in combination with a stop-motion for automatically tripping said stopping instrumentality into action at a predetermined stage in the revolution of said lay-driving shaft, whereby the loom is stopped with its operating parts in prescribed positions.

2. An upright loom having a progressively-acting spring-actuated stopping instrumentality adapted to bring the operating parts of the loom to rest by its progressive action during a prescribed part of a single revolution of the lay-driving shaft, and a stop-motion adapted to trip said stopping instrumentality into action at a predetermined stage in the revolution of said lay-driving shaft, whereby the loom is stopped with its operating parts in prescribed positions.

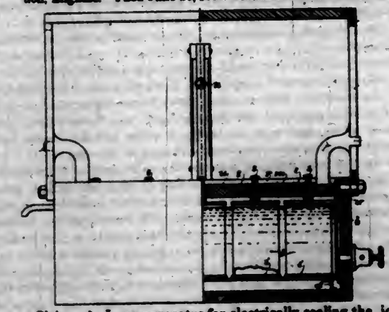
3. In a loom, a plurality of stop-motions, a progressively-acting spring-actuated stopping instrumentality adapted to bring the operating parts of the loom to rest by its progressive action during a prescribed part of a single revolution of the lay-driving shaft, and connections common to all of said stop-motions for tripping said stopping instrumentality into action at predetermined stages in the revolution of said lay-driving shaft.

4. In a loom, a warp stop-motion, a weft stop-motion, a shuttle stop-motion and warp-slacking mechanism controlled by said shuttle stop-motion, a progressively-acting spring-actuated stopping instrumentality adapted to bring the operating parts of the loom to rest by its progressive action during a prescribed part of a single revolution of the lay-driving shaft, and connections common to said warp stop, shuttle stop and weft stop motions, whereby the said stopping instrumentality is automatically tripped into action at predetermined stages in the revolution of said lay-driving shaft, as and for the purposes set forth.

5. In a loom, a warp stop-motion, a shuttle stop-motion, warp-slacking mechanism controlled by said shuttle stop motion, a progressively-acting spring-actuated stopping instrumentality adapted to bring the operating parts of the loom to rest by its progressive action during a prescribed part of a single revolution of the lay-driving shaft, and connections common to said warp stop and shuttle stop motions, whereby the said stopping instrumentality is automatically tripped into action at predetermined stages in the revolution of said lay-driving shaft, as and for the purposes set forth.

6. In a loom, a warp stop motion and a weft stop-motion, a progressively-acting spring-actuated stopping instrumentality adapted to bring the operating parts of the loom to rest by its progressive action during a prescribed part of a single revolution of the lay-driving shaft, and connections common to said warp stop and weft stop motions, whereby the said stopping instrumentality is automatically tripped into action at predetermined stages in the revolution of said lay-driving shaft, as and for the purposes set forth.

7. In a loom, a shuttle stop-motion, warp-slacking mechanism controlled by said shuttle stop-motion, and a weft stop-motion, a progressively-acting spring-actuated stopping instrumentality adapted to bring the operating parts of the loom to rest by its progressive action during a prescribed part of a single revolution of the lay-driving shaft, and connections common to said shuttle stop and weft stop motions, whereby the said stopping instrumentality is automatically tripped into action at predetermined stages in the revolution of said lay-driving shaft, as and for the purposes set forth.



8. In a loom, a lay and a yielding breast-beam adapted to be moved in the direction of the beat-up.

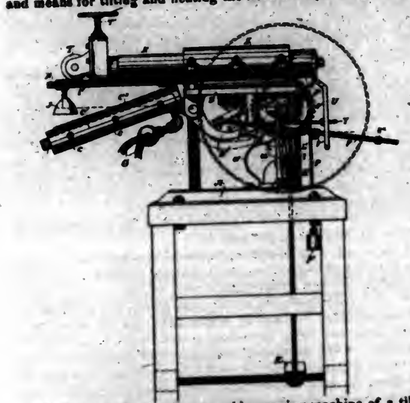
9. In a loom, a lay, a yielding breast-beam adapted to be moved in the direction of the beat-up, and means for limiting the range of movement of the said breast-beam toward the lay.

10. In a loom employing a warp stop-motion and a self-tightening spring-actuated brake-strap, substantially such as described; a manually-operative lever for releasing said brake-strap from the brake-wheel; a link connecting said lever with a part of said warp stop-motion, whereby when the said lever is lifted to release the brake-strap, the warp stop-motion is concurrently adjusted in position to be brought into operation if a warp-thread breaks after the loom has been again started.

11. In a loom, in combination with the warp roll, a rope secured at one end to the frame and wound around the hub of the warp-roll; a windlass to which the other end of said rope is affixed, and an adjustably-weighted lever having a pawl-and-ratchet connection with said windlass, as and for the purposes set forth.

605,604. MEANS FOR HERMETICALLY SEALING METAL BOXES, &c. JULES GUESSANT, Deal, and ARCHIBALD C. BUTTIFANT, London, England. Filed June 29, 1896. Serial No. 597,264. (No model.)

Claim.—1. In an apparatus for electrically sealing the joints or seams of metal boxes or cans, a trough or receptacle, a basket removably placed therein and composed of conducting material, and a movable cover or lid for the trough or receptacle adapted to be supported upon the box or can, and carrying a contact, said basket and cover or lid being connected with the opposite poles of an electric circuit.



2. In an apparatus for electrically sealing the joints or seams of metal boxes or cans, the combination of a trough or receptacle, a metallic basket removably supported therein, having a projection or stand for retaining the box or can in position, and a movable lid or cover for the trough having a yielding pin or contact to rest upon the top portion of the box or can, said pin and basket being electrically connected with the opposite poles of an electric circuit.

3. In an apparatus for electrically sealing the joints or seams of metal boxes or cans, the combination, of a trough or receptacle, a metallic basket removably supported therein, having a series of movable stands or projections for retaining a series of boxes or cans in position, a movable cover or lid for the trough having a series of yielding pins or contacts to rest one upon each box or can, and a metal plate on the lid or cover in contact with the pins, said plate and basket being electrically connected with opposite poles of circuit.

605,605. CAN-SIDE-SEAM-FUSING MACHINE. JULES GUESSANT, Deal, and ARCHIBALD C. BUTTIFANT, London, England. Filed Dec. 27, 1897. Serial No. 663,573. (No model.)

Claim.—1. In a can-side-seaming machine, a slotted perforated

tiltable cylindrical horn, guides along the slot, a hinged counterweighted plate covering the guides, a roller passing over said plate, and means for tilting and heating the horn and operating the roller.

2. The combination in a can-side-seaming machine of a tiltable horn having a longitudinal slot on its upper surface, perforations on each side, guides on the horn parallel with the slot and at a short distance from its edges so as to form a channel adapted to receive the seam of a can, and a perforated burner-pipe in the horn with one or more tubes attached to the burner-pipe and connected with a suitable supply of inflammable vapor.

3. The combination in a can-side-seaming machine of a tiltable horn having a longitudinal slot on its upper surface, perforations on each side, guides on the horn parallel with the slot and at a short distance from its edges and a perforated burner-pipe in the horn with tubes attached to the burner-pipe and connected with a suitable supply of inflammable vapor and means for tilting the horn.

4. In the can-side-seaming machine, the combination of a tiltable cylindrical horn having a longitudinal slot on its upper surface, and perforations on each side, guides on the horn parallel with the slot and at a short distance from its edges, and a perforated burner-pipe inside the horn, with tubes attached to the burner-pipe and connected with a suitable supply of inflammable vapor, means for tilting the horn, and a horizontal rack-bar having a roller attached to its forward end and adapted to pass over said seam of the can.

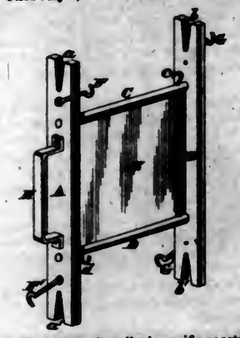
5. In a can-side-seaming machine the combination of a tiltable cylindrical horn having a longitudinal slot on its upper surface, perforations on each side, guides on the horn parallel with the slot and a perforated burner-pipe inside the horn, with tubes attached to the burner-pipe and connected with a supply of inflammable vapor, means for tilting the horn, a horizontal rack-bar having a roller attached to its forward end and adapted to pass over said seam of the can and a presser connected with said roller so as to regulate its action on the seam of the can.

6. The combination in a can-side-seaming machine of a tiltable cylindrical horn having a longitudinal slot on its upper surface, perforations on each side, guides on the horn parallel with the slot and a perforated burner-pipe inside the horn with tubes attached to the burner-pipe and connected with a supply of inflammable vapor, means for tilting the horn, a horizontal rack-bar having a roller attached to its forward end and adapted to press over said seam of the can, a presser connected with said roller so as to regulate its action on the seam of the can, a toothed wheel meshing with said rack-bar and loosely mounted to a shaft connected with driving power and mechanism for reversing the motion of said wheel.

605,606. ICE-CREAM FREEZER. EDGAR C. HILL, Horse Cave, Ky. Filed Apr. 21, 1897. Serial No. 633,067. (No model.)

Claim.—1. In an ice-cream freezer, the combination with a central standard, of an ice vessel having a thimble provided with a cap, a non-removable cover for said ice vessel, a cream vessel removably secured to said cover and having an interior beater and scraper and a sleeve having a tip removably fitted into said cup whereby a tight but severable joint is formed so that the cream vessel may be removed.

2. In an ice-cream freezer, the combination with a centrally-shouldered standard, of an ice vessel having a thimble mounted on the standard and upon its shoulder, a cream vessel removably secured to the cover of the ice vessel, a yoke on the upper end of the standard, a sleeve rotatably mounted in said yoke at one end and connected to the cream vessel at the other, a tight but separable joint between said thimble and sleeve between the two vessels, a lower yoke on the sleeve and a spring-controlled pivoted beater and scraper carried by said yoke.



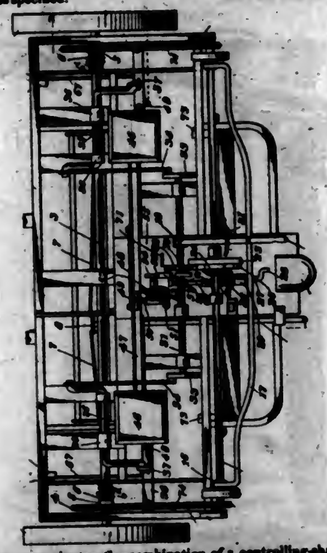
3. In an ice-cream freezer, the combination with an ice vessel having a cover and turn-buttons, of a cream vessel removably fitted in said cover and having inclined lugs projecting from the cream vessel for said turn-buttons, and an annular body fitted upon a gasket carried by the cover.

4. In an ice-cream freezer, the combination with a base having a bracket provided with separate wings, of a standard pivoted in the bracket between the said wings, the wing having a series of perforations, and a pin to hold the standard in adjusted positions.

5. In an ice-cream freezer, the combination with a central standard, of an ice vessel having a thimble extending through it, and a cup on the thimble with a conical mouth, of a cream vessel a sleeve secured thereto and a tip on the sleeve having a conical end fitted to the cup, said central standard passing through said sleeve, cup and thimble, substantially as shown and described.

605,607. CLOTHES-LINE HOLDER. WILLIAM KOOB, Lawrenceburg, Ind. Filed July 2, 1897. Serial No. 643,941. (No model.)

Claim.—1. The within-described specific construction of non rotatable clothes-line holder, which device includes a bar provided with a retainer, a pair of laterally-projecting pins and a longitudinal passage widest at its receiving end, and converging toward its other end, said parts being so combined and arranged as to enable a line to be wound around said pins, then bent at a right angle to traverse said passage, near its narrowest end, and to be secured therein by said retainer, in order that said holder may be hung up by said line without causing it to uncoil from said pins, all as set forth.



2. A suspension clothes-line holder comprising the side bar A, having notched ends *a a'*, and hooks F, F', another and parallel side bar B, having notched ends *b, b'*, and hooks G, G', and stretchers C, D, rigidly uniting said bars, the whole constituting a non-rotatable device capable of being held by hand, in the manner herein described

---

605,608. CORN-PLANTER. LARS H. LARSON, Hartland, Minn. Filed Aug. 31, 1897. Serial No. 650,133. (No model.)

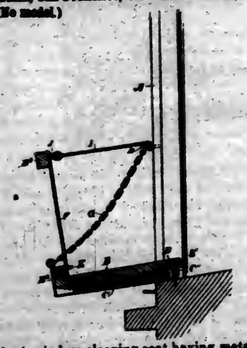
Claim.—1. In a corn-planter, the combination of a shaft having clutch-heads thereon, disks with which the said clutch-heads engage.

means for operating the said disks, another shaft operated by the aforesaid shaft and having disks on the ends thereof, crank-shafts attached to said disks, and vertically-reciprocating markers connected to and operated by the said crank-shafts, substantially as and for the purposes specified.

2. In a corn-planter, the combination of a controlling-shaft provided with an arm, a pawl supported by a slide-rod, a keeper engaging said pawl, a ratchet-wheel, a seed-slide, gearing in connection with said ratchet-wheel and seed-slide, and seedboxes with which said slide coacts, substantially as and for the purposes specified.

3. In a corn-planter, the combination of a drive-shaft, another shaft in connection therewith having a gear thereon, a controlling-shaft engaging said gear, crank-shafts connected to said controlling-shaft, vertically-reciprocating markers operated by the said crank-shafts, and an adjustable turn-rod carrying a pinion adapted to engage the said gear, and to adjust the said markers, substantially as and for the purposes specified.

4. In a corn-planter, the combination of a shaft having a gear thereon, means for operating said shaft, a controlling-shaft carrying the pinion adapted to mesh with said gear, and provided with an arm, crank-shafts connected to said controlling-shaft, vertically-reciprocating markers attached to and operated by said crank-shafts, a yielding pawl adapted to be engaged by the arm of the controlling-shaft, a ratchet-wheel and gearing actuated by the said yielding pawl, a feed-slide connected to the gearing actuated by the pawl, seedboxes with which the said slide engages, and means for throwing the several parts in and out of gear, substantially as and for the purposes specified.



605,609. FASTENER FOR STRAPS. FRANK L. MOORE, Chatham, N. J. Filed Mar. 19, 1898. Renewed May 13, 1898. Serial No. 680,632. (No model.)

Claim.—1. The strap-attaching plate formed with a strap-receiving keeper and provided with means for attachment to the strap, in combination with a straining-lever hinged to said attaching-plate, carrying a strap-buckle intermediate its ends, and its end adapted to engage said keeper and be secured thereto by the strap passing over it and through said keeper.

2. The strap-attaching plate formed with a strap-receiving keeper and provided with means for attachment to the strap, in combination with a straining-lever hinged to said attaching-plate, carrying a strap-buckle intermediate its ends and formed with a slot in its free end to receive the said keeper and be held down thereon by the strap passing therethrough.

605,610. WINDOW-CLEANING SEAT. CARL A. MÜLLER and GEORGE HINMAN, San Francisco, Cal. Filed Jan. 21, 1898. Serial No. 667,900. (No model.)

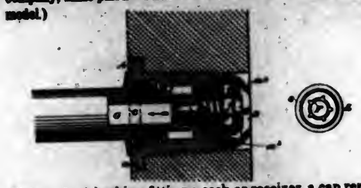
Claim.—1. A window-cleaning seat having metallic strips across the ends, said strips projecting interior to the inner edge of the seat and being upturned and slotted as shown, in combination with screws fixed in the window-sill and having heads with which the upturned slotted ends engage and lock.

2. A window-cleaning seat consisting of a seat-piece having transverse strips of metal across the ends, projecting beyond the interior edge and upturned and slotted, headed screws or bolts fixed in the window-seat with which said slotted bars engage and lock, chains fixed to the outer edge of the seat extending diagonally upward having hook attachments upon the upper ends and wall attachments with which they are engaged so as to support the outer edge of the seat.

3. In a window-cleaning seat, a bottom board having transverse metallic strips across the ends, said strips extending beyond the inner edge of the seat and being upturned and slotted, headed screws fixed in the window-sill with which said slotted ends engage and lock, vertical posts extending upwardly from the outer edge of the seat having a transverse bar fixed across the upper ends, chains connecting with the outer edge of the seat and with attachments fixed to the outer part of the wall above the level of the seat, and hooks connecting with the top of the vertical bars at the ends of the transverse rail having the inner ends connected with the attachments upon the wall to form a support and guard.

4. In a window-cleaning seat, a base having metal strips secured across its ends, the inner ends of said strips being turned upwardly and slotted, screw-eyes with which said inner slotted ends are adapted to engage and lock, supplemental flaps hinged to the inner edge of the seat adapted to fold down over the screw-eyes and slotted metal ends, and suspending chains and hooks connecting with the outer edge of the seat and connecting with attachments upon the wall above the level of the seat.

605,611. STREET-SPRINKLING, IRRIGATING, AND FIRE-EXTINGUISHING SYSTEM. ALEXANDER MCGOUN, Oakland, Cal. Filed Aug. 10, 1897. Serial No. 647,575. (No model.)



Claim.—1. In a system of water-supply, a pipe having one or more rows of holes of decreasing diameters, said holes provided with counterbored bushings, and polygonal collars on the pipes adapted to receive a tool or device whereby they may be rotated.

2. In a system of water-supply for extinguishing fires, a perforated pipe connected with a source of supply and journaled on the apex of the roof of a building, and means whereby the discharge from the pipe may be directed to either slope of the roof.

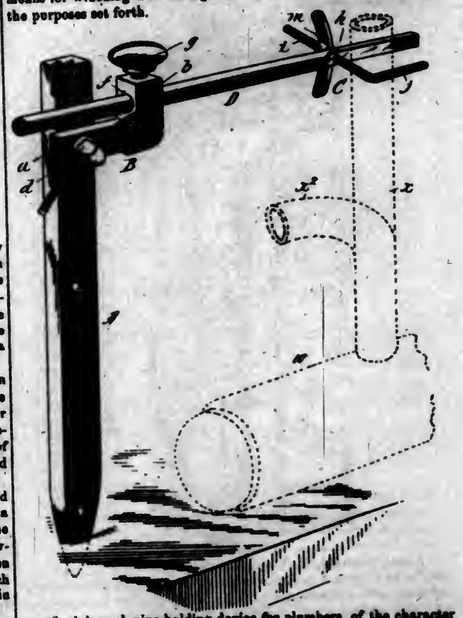
3. A sprinkling device consisting of a pipe section or sections, having a line of perforations along one side, brackets by which said pipe is supported along the ridge of a house, a direction-board sup-

ported and turnable beneath the pipe with attachments to tilt the board and direct the discharge-jets to either side of the ridge.

605,612. BUSHING AND FAUCET FOR BARRELS. WILLIAM C. RAWLEY, San Francisco, Cal., assignor to the American Faucet Company, same place. Filed Oct. 22, 1897. Serial No. 656,008. (No model.)

Claim.—1. A bushing fitting a cask or receiver, a cap removably fitting the inner end of said bushing having a central aperture with an interiorly-formed valve-seat, a second seat formed within the bushing and opposed to the first-named valve-seat with a space between the two, a valve movable between the two seats so as to close upon one or the other and an annular shoulder formed around the inner surface of the removable cap so as to close against and form a joint with the outer periphery of the inner valve-seat.

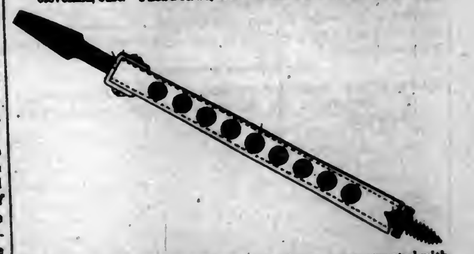
2. A bushing fitting a cask or receiver having screw-threads upon the inner end, and an annular groove or channel adapted to receive a removable annular ring forming a seat against which the interior face of a valve movable within the bushing is adapted to close, a removable screw-threaded cap fitting the threads upon the inner end of the bushing having a central opening and a ledge or shoulder adapted to fit against the removable seat when the cap is screwed in place.



3. A bushing fitting a cask or receiver having a screw-threaded interior end and a correspondingly-threaded removable cap with a centrally-formed opening and valve-seat, shoulders formed upon the interior of the cap and upon the inner end of the bushing, a removable ring adapted to fit and be clamped between said shoulders when the cap is in place, said ring forming an inner seat for a valve which is movable between the said inner seat and the outer one formed in the cap.

4. A bushing fitting a cask or receiver having a screw-threaded removable cap upon the inner end, shoulders formed upon the inner end of the bushing and upon the interior of the cap, an annular ring adapted to be clamped between said shoulders and forming a seat, a double-faced valve having a tubular stem, and movable inwardly to close one face against said seat and outwardly to close the other face against a corresponding seat formed centrally through the cap, screw-threads upon the enlarged central portion of the valve-stem engaging corresponding threads in the interior of the bushing, a head formed upon the inner end of the tubular valve-stem, a faucet-barrel having a corresponding formation upon the inner end to engage said head and turn the valve, spiral locking lugs upon the faucet-barrel, corresponding lugs upon the inner surface of the bushing, and an annular elastic disk inclosing the faucet-stem interior to the locking-lugs to prevent leakage.

5. A bushing fitting a cask or receiver having a removable cap on the inner end with a central aperture and an interior valve-seat, a second seat opposed thereto within the bushing and forming a space between the two, said cap having an internal shoulder opposing the valve-seat within the bushing, to make a joint therewith, a valve movable between the two seats, and passages through which liquid may pass when the valve stands intermediate between the seats, a chamber within the bushing adapted to receive the inner end of a faucet, a head upon the valve-stem and a correspondingly-shaped formation upon the inner end of the faucet which will engage the head of the valve-stem when the faucet is introduced, spiral lugs in the interior of the bushing and also around the faucet-barrel adapted to engage and lock the faucet simultaneously with the movement of the valve when the faucet is turned, and a washer adapted to make a tight joint between the faucet and the bushing, said washer having an inclosing cap turnable upon the faucet-barrel, whereby the latter is movable within the washer after the latter has become seated.

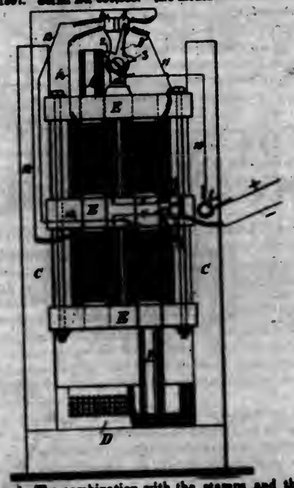


605,618. BRANCH-PIPE-HOLDING DEVICE FOR PLUMBERS' USE. OTTO F. RICHTER, Holyoke, Mass. Filed Nov. 26, 1897. Serial No. 660,771. (No model.)

Claim.—1. A branch-pipe-holding device for plumbers, of the character described, consisting of a spike constituting an upright support, a member pivotally mounted and adjustably confined on the side of the support, having the perforation *f* therethrough in a line coincident with the plane of swinging movement of the said adjustable member, the rod D having a supporting engagement, and endwise, and also rotational adjustments in and through said perforation, and a thumb-screw for confining the rod in its adjusted positions, and a clamp provided at the extremity of the said rod and means for widening and closing the clamp, substantially as and for the purposes set forth.

2. A branch-pipe-holding device for plumbers, of the character described, consisting of a spike-support A, the L-shaped member B pivotally mounted and adjustably confined on the side of the support, having the perforation *f* through a member thereof in a line coincident with the plane of swinging movement of the said adjustable member, the round rod D having a supporting engagement, and endwise adjustment, in and through said perforation, and a thumb-screw for confining the rod in its endwise position, the L-shaped clamp C having its screw-threaded shank passed through a perforation A which is transversely provided in the end portion of the rod D and the thumb-nut *m* screwing on said shank and against the rod, all substantially as and for the purposes set forth.

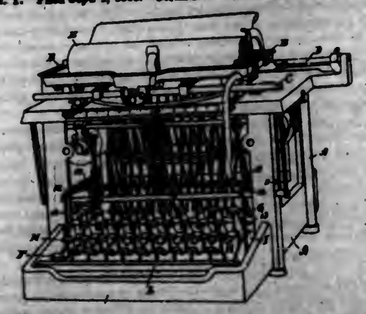
605,614. COMBINED AUGER AND CUTTER. LOUIS H. SEGLER, Cleveland, Ohio. Filed Dec. 24, 1897. Serial No. 663,413. (No model.)



Claim.—1. The chisel-edged casing for the auger constructed with greater cross-section at its lower cutting end than higher up, whereby the casing is given clearance its entire length, in combination with the auger having a lead-screw of a size and length sufficient to draw the said casing through the wood, substantially as described.

2. The chisel-edged casing provided with openings in its sides to discharge the cuttings and reduced from its lower to its upper end to form a clearance thereof in the hole it cuts, in combination with the auger having a lead-screw constructed to feed the auger and draw the chisel through the wood and square the hole while the auger is at work, substantially as described.

3. The auger having a shoulder on the neck thereof above the thread, the casing having openings in its top and securing-pieces connecting said casing and auger entering said openings and engaging said shoulder, whereby the endwise thrust of the casing comes on said pieces, substantially as described.



605,615. CRB-STAMP. DAVID M. SMITH, Pasadena, Cal. Filed June 9, 1897. Serial No. 639,285. (No model.)

Claim.—1. The combination with the stamps and the electro-magnets for actuating the same, of a switch that is actuated by an upward movement of one stamp to change the circuit connections for raising another stamp, substantially as specified.

2. The combination with two stamps and the electro-magnets for actuating the same, of circuit connections and a switch that is changed by the upward movements of the stamps alternately, for energizing the magnets and raising one stamp and accelerating the fall of the other, substantially as specified.

605,616. TYPE-WRITING MACHINE. PHILIP W. SOUTHGATE, Worcester, Mass., assignor to The Wyckoff, Seamans & Benedict, Ilion, N. Y. Filed Sept. 1, 1893. Serial No. 484,694. (No model.)

Claim.—1. In a type-writing machine, the combination of character-controlling keys, a space-key, and means operated by or from the space-key for indicating whether or not the space-key should be operated or struck next, substantially as described.

2. In a type-writing machine, the combination of character-controlling keys, a space-key, and a signal operated by or from the space-key for indicating whether or not the space-key should be operated or struck next, substantially as described.

3. In a type-writing machine, the combination of character-controlling keys, a space-key, and a visual signal operated by or from the space-key for showing whether or not the space-key should be operated or struck next, substantially as described.

4. In a key-operated type-writing machine, the combination of a signal, and means controlled by a space-key for operating said signal for indicating whether or not the space-key should be operated or struck next, substantially as described.

5. In a type-writing machine, the combination of character-controlling keys, a space-key, a plate or frame having an opening therein, an indicator behind said plate or frame and partially exposed through said opening, and connections between said indicator and said keys, whereby the character-keys and the space-key respectively move said indicator to expose different or unlike portions thereof to view, substantially as described.

6. In a key operated type-writing machine, the combination of a signal, means for giving a step-by-step feed movement to the carriage, and connections whereby said signal is operated or controlled to indicate whether or not the space-key should be operated or struck next, substantially as described.

7. In a type-writing machine, the combination with a paper-carriage and the printing and feeding devices, and means for indicating to the operator whether or not the paper-carriage has been spaced after a character has been printed to provide for a blank space before the beginning of the next word, substantially as described.

8. The combination of an indicator and means for connecting said indicator with the operative parts of a type-writing machine so that the indicator will be moved into one position to show that the machine was last operated to print, and into a different position to show that the machine was last operated to space, substantially as described.

9. The combination of a keyboard having character-keys and a space-key, an indicator constructed to show whether the space-key or character-key was last operated, and connections for moving the indicator into position to show that the machine was last operated to print when a character-key is operated, and into a different position to show that the machine was last operated to space when the space-key is operated, substantially as described.

10. In a type-writing machine, the combination of character-keys, a space-key, a universal bar actuated by the character-keys, an indicator constructed to show whether the character-key or the space-key was last operated, and connections for moving the indicator into position to show that the machine was last operated to space when the space-key is operated, and into a different position to show that the machine was last operated to print when the universal bar is operated, substantially as described.

11. In a type-writing machine the combination of a rock-shaft, an indicator controlled thereby, means for turning the rock-shaft in one direction when a character is printed and means for turning the rock-shaft in the opposite direction when a blank space is left, substantially as described.

12. In a type-writing machine the combination of a keyboard having character-keys and a space-key, a rock-shaft and universal bar operated by the character-keys and connected to the rock-shaft for turning it in one direction, means controlled by the space-key for turning the rock-shaft in the opposite direction and an indicator connected to the rock-shaft, substantially as described.

13. In a type-writing machine the combination of a keyboard having character-keys and a space-key, a rock-shaft having arms extending in opposite directions, a frame controlled by the character-keys and secured to the arms which extend from the rock-shaft in one direction, a frame controlled by the space-key and secured to the arms which extend from the rock-shaft in the opposite direction and an indicator connected to the rock-shaft, substantially as described.

14. The combination in a type-writing machine of a rock-shaft 10 mounted on center-screws 11 in the side frames of the machine and provided with arms 12, carrying frames which are controlled by the character-keys and the space-key respectively and an arm 9 secured to the rock-shaft and connected to an indicator by a rod 18, substantially as described.

15. The combination of the keyboard having character-keys, upper and lower case keys, located one at each side of the keyboard of a spacing-frame carrying a space-bar extending across the front of the keyboard of a rock-shaft located above the keyboard and carrying wires 15 which extend down between the upper and lower case key levers and the character-key levers and are connected by a bar 16, of a frame 13, also connected to the rock-shaft and having bends or offsets 14 which are adapted to be engaged by the spacing-frame and an indicator connected to the rock-shaft, substantially as described.

16. The combination of a type-writing machine and an indicator constructed to show whether the machine was last operated to print a character or to leave a space, the parts of the indicator being substantially counterbalanced, substantially as set forth.

605,617. APPARATUS FOR POPPING CORN. RASMUS O. STORMAN, Des Moines, Iowa. Filed Nov. 14, 1891. Serial No. 411,867. (No model.)

Claim.—1 An apparatus for popping corn, comprising a con-

taining-receptacle into which kernels of corp to be treated are deposited which receptacle is rotatably mounted, means for rotating said receptacle, said receptacle having an opening or openings in the side which is parallel to the axis of the same and separating and discharging mechanism, whereby the popped corn is automatically removed from the receptacle through the said opening or openings and in advance of the said separating and discharging mechanism, the unpopped corn remaining within the receptacle.

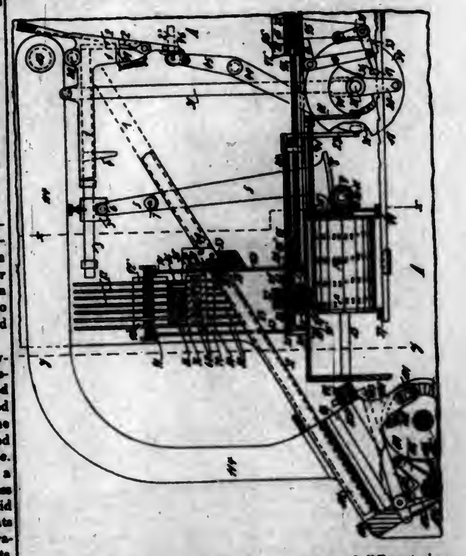
2. An apparatus for popping corn, comprising a cylindrical containing vessel having an opening in the side thereof conveying mechanism rotatably mounted within said receptacle, clearing mechanism connected to and extending within said receptacle, and means for rotating said conveying mechanism in order that the popped corn may be separated out from the mass within the receptacle caused to fall upon the clearing mechanism and discharged through the said opening.

3. In an apparatus for popping corn, the combination with a pivotally-mounted cylindrical containing-receptacle having a discharge-opening in one side thereof, of a revolving rake rotatably mounted concentrically within said receptacle, clearing mechanism connected to said receptacle and acted upon by the rake-teeth to clear the same, conjunctively-operating gear-wheels for rotating the rake and means for causing one of said gear-wheels to oscillate the receptacle.

4. In an apparatus for popping corn, the combination with a corn containing receptacle and means of ingress thereto and egress therefrom, of a revolving rake concentrically mounted within said receptacle, and means for rotating said rake, and a plurality of slats fixed to the interior of said receptacle at slight differences of separation the teeth of the rake traveling in the spaces between said slats, whereby the ends of the rake-teeth are prevented from contacting with the corn.

5. An apparatus for popping corn, comprising a containing-receptacle pivotally mounted upon a suitable support and having means of ingress thereto and egress therefrom, a rake rotatably mounted concentrically within said receptacle, a train of gearing connected to and operating said rake, pins fixed to and projecting from one of the members of said gearing, which pins in their traverse successively engage with and impart a rotary motion to the said receptacle, and means for causing said receptacle to resume its normal position after each contact of the several pins.

605,618. JUSTIFYING DEVICE FOR TYPE-SETTING OR OTHER MACHINES. ERNST WERTHEIMER, Berlin, Germany. Filed Mar. 12, 1896. Serial No. 582,956. (No model.) Patented in England Mar. 6, 1895, No. 4,754



Claim.—1. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with different signs or marks at different places, indicating each independently of the other by its place a particular size and by its character a certain number of that size of spaces, substantially as described.

2. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with readable signatures at different places, indicating each independently of the other by its place a particular size and by its readable signature the number of that size of spaces, substantially as described.

3. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with indentures of different depths at different places, indicating each independently of the other by its place a particular size and by its depth a certain number of that size of spaces, substantially as described.

4. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with projections of different heights at different places, indicating each independently of the other by its place a particular size and by its height a certain number of that size of spaces, substantially as described.

5. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with different signs or marks at different places, indicating each independently of the other by its place a particular size and by its character a certain number of that size of spaces, and means for selecting that portion of the register which contains the signs or marks indicating the spaces to justify a given line, substantially as described.

6. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with different signs or marks at different places, indicating each independently of the other by its place a particular size and by its character a certain number of that size of spaces, and means for bringing into sight of the operator that portion of the register which contains the signs or marks indicating the spaces required to justify a given line, substantially as described

7. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with different signs or marks at different places, indicating each independently of the other by its place a particular size and by its character a certain number of that size of spaces, a space-feeding mechanism, and means for presenting or connecting to the said space-feeding mechanism that portion of the register which contains the signs or marks indicating the spaces required to justify a given line, substantially as described.

8. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with different signs or marks at different places, indicating each independently of the other by its place a particular size and by its character a certain number of that size of spaces, means for selecting that portion of the register which contains the signs or marks indicating the spaces required to justify a given line, a space-feeding mechanism, and means for stopping the line at each spacing, substantially as described.

9. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with different signs or marks at different places, indicating each independently of the other by its place a particular size and by its character a certain number of that size of spaces, and means for shifting the register by the line to be justified, substantially as described.

10. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with different signs or marks at different places, indicating each independently of the other by its place a particular size and by its character a certain number of that size of spaces, and means for shifting the register in one direction by the line to be justified and in another direction in accordance with the number of word-spacings contained in that line, substantially as described.

11. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with different signs or marks at different places, indicating each independently of the other by its place a particular size and by its character a certain number of that size of spaces, a plate or block for adjusting the line to be justified, and means for controlling the register by the line-adjusting movement, substantially as described.

12. In an apparatus employing movable spaces of different sizes to justify composed lines a space selecting or predetermining register provided with different signs or marks at different places, indicating each independently of the other by its place a particular size and by its character a certain number of that size of spaces, a space-feeding mechanism, means for presenting or connecting to the said space-feeding mechanism that portion of the register which contains the signs or marks indicating the spaces required to justify a given line, and means for controlling the space-feeding mechanism by the register, substantially as described.

13. In an apparatus for justifying lines composed by setting-machines the combination of movable stops controlling the feeding of spaces, ratchet devices intermittingly actuating the said stops, and means for oscillating the said ratchet devices by the common key-stroke of the setting machine, substantially as and for the purposes described.

14. In an apparatus for justifying lines composed by setting-machines the combination of movable stops controlling the feeding of spaces, ratchet devices intermittingly actuating the said stops, and an escapement or catch for stopping the line at each spacing, substantially as and for the purposes described.

15. In an apparatus for justifying lines composed by setting-machines the combination of movable stops controlling the feeding of spaces, an escapement or catch for stopping the line at each spacing, and means for actuating the said escapement or catch by the common key-stroke of the setting-machine, substantially as and for the purposes described.

16. In an apparatus for justifying lines composed by matrix or die setting machines an inclined matrix or die channel for assembling the provisional line, means for justifying the same and means for forwarding and delivering the line by gravity, substantially as and for the purposes described.

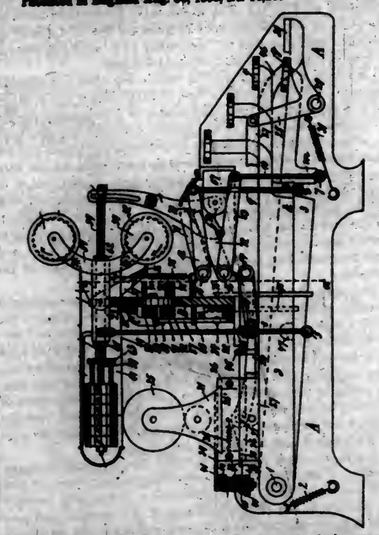
17. In an apparatus for justifying lines composed by matrix or die setting machines the combination of an inclined matrix or die channel, a space-feeding mechanism, and an escapement or catch for stopping at each spacing the line descending by gravity, substantially as and for the purposes described.

18. In an apparatus for justifying lines composed by matrix or die setting machines the combination of an inclined matrix or die channel, a space-feeding mechanism, and an escapement or catch for detaching word by word at each spacing, the matrices or dies descending by gravity, substantially as and for the purposes described.

19. In an apparatus for justifying lines composed by matrix or die setting machines the combination of an inclined matrix or die channel, a space-feeding mechanism, an escapement or catch for stopping at each spacing the line descending by gravity and means for withdrawing the provisional spaces, substantially as and for the purposes described.

20. In an apparatus for justifying lines composed by matrix or die setting machines the combination of a horizontal matrix or die assembling receptacle, an inclined channel for justifying the line and delivering the same by gravity, and means for bringing the assembling-receptacle into line with the said inclined channel, substantially as and for the purposes described.

21. In an apparatus for justifying lines composed by matrix or die setting machines the combination of an inclined matrix or die channel, an escapement or catch for stopping at each spacing the line descending by gravity, and a letter-matrix or letter-die provided with a nick or recess in its upper shoulder, substantially as and for the purposes described.



22. In an apparatus for justifying lines composed by matrix or die setting machines the combination of an inclined matrix or die channel, a space provided with a nick and means for withdrawing the space by way of the said nick, substantially as and for the purposes described.

23. In an apparatus for justifying lines composed by setting-machines the combination of two levers swinging in opposite directions and pushers or drivers connected to the said levers and entering into the type-channel, substantially as and for the purposes described.

24. In an apparatus for justifying lines composed by setting-machines the combination of provisional spaces extending at the top and the bottom of the line and bridges for stopping the line at each spacing, substantially as and for the purposes described.

25. In an apparatus for justifying lines composed by setting-machines the combination of provisional spaces extending at the top and the bottom of the line, movable bridges for stopping the line at each spacing, and means for actuating the said bridges at each spacing, substantially as and for the purposes described.

605,619. TYPE-WRITING MACHINE. ERNST WERTHEIMER, Berlin, Germany. Filed Apr. 2, 1896. Serial No. 585,697. (No model.) Patented in England Aug. 30, 1895, No. 16,209

Claim.—1. In a type-writing machine, in which the types are arranged in a plurality of circular sections and of longitudinal rows on the surface of a type-cylinder, the combination of a swinging toothed segment, pivoted to the stationary frame of the machine and provided with a pin or pins, of levers likewise pivoted to the stationary frame of the machine and engaging with the said pin or pins for swinging and stopping the swinging toothed segment, of frames suspended from the said levers, each of the said frames being actuated by the keys corresponding to one and the same longitudinal row of types of the type-cylinder, and of means for controlling the turning movement of the type-cylinder by the said swinging segment.

2. In a type-writing machine, in which the types are arranged in a plurality of circular sections and of longitudinal rows on the surface of a type-cylinder, the combination of a swinging lever, pivoted to the stationary frame of the machine and provided with a pin or pins, of levers likewise pivoted to the stationary frame of the machine and engaging with the said pin or pins for swinging and stopping the swinging lever, of frames suspended from the said levers, each of the said frames being actuated by the keys corresponding to one and the same circular section of types of the type-cylinder, and of means for controlling the longitudinal shifting movement of the type-cylinder.

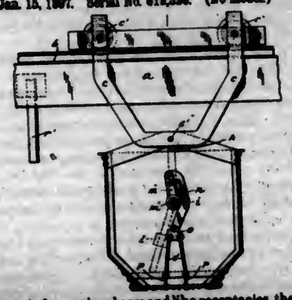
3. In a type-writing machine, in which the types are arranged in a plurality of circular sections and of longitudinal rows on the surface of a type-cylinder, the combination of a swinging part, pivoted to the stationary frame of the machine and provided with a pin or pins, of levers likewise pivoted to the stationary frame of the machine and engaging with the said pin or pins for swinging and stopping the said swinging part, of frames suspended from the said levers and depressed by the key stroke, of springs inserted between the said frames and the said levers, and of means for controlling the type-cylinder by the said swinging part.

4. In a type-writing machine, in which the types are arranged in a plurality of circular sections and of longitudinal rows on the surface of a type-cylinder, the combination of a swinging part pivoted to the stationary frame of the machine and provided with a pin or pins, of levers likewise pivoted to the stationary frame of the machine and engaging with the said pin or pins for swinging and stopping the said swinging part, of levers controlling by pin-and-cam or by roller-and-cam action the movement of the said swinging and stopping levers, of frames suspended from the said controlling-levers and depressed by the key stroke, and of means for controlling the type-cylinder by the said swinging part.

5. In a type-writing machine, in which the types are arranged in a plurality of circular sections and of longitudinal rows on the surface of a type-cylinder, the combination of a swinging toothed segment pivoted to the stationary frame of the machine and provided with a pin or pins, of levers likewise pivoted to the stationary frame of the machine and engaging with the said pin or pins for swinging

and stopping the swinging toothed segment, of levers controlling by pin-and-cam or by roller-and-cam action the movement of the said swinging and stopping levers, of frames suspended from the said controlling-levers, each of the said frames being actuated by the keys corresponding to one and the same longitudinal row of types of the type-cylinder, and of means for controlling the turning movement of the type-cylinder by the said swinging segment.

6. In a type writing machine, in which the types are arranged in a plurality of circular sections and of longitudinal rows on the surface of a type-cylinder, the combination of a swinging lever pivoted to the stationary frame of the machine and provided with a pin or pins, of levers likewise pivoted to the stationary frame of the machine and engaging with the said pin or pins for swinging and stopping the swinging lever, of levers controlling by pin-and-cam or by roller-and-cam action the movement of the said swinging and stopping levers, of frames suspended from the said controlling-levers, each of the said frames being actuated by the keys corresponding to one and the same circular section of types of the type-cylinder, and of means for controlling the longitudinal shifting movement of the type-cylinder.



7. In a type-writing machine, in which the types are arranged in a plurality of circular sections and of longitudinal rows on the surface of a type-cylinder, the combination of a swinging part pivoted to the stationary frame of the machine and provided with a pin or pins, of levers likewise pivoted to the stationary frame of the machine and engaging with the said pin or pins for swinging and stopping the swinging part, of toggle-levers controlling the movement of the said swinging and stopping levers, of frames suspended from the toggle-levers and depressed by the key stroke, and of means for controlling the type-cylinder by the said swinging part.

8. In a type-writing machine, in which the types are arranged in a plurality of circular sections and of longitudinal rows on the surface of a type-cylinder, the combination of a swinging toothed segment, pivoted to the stationary frame of the machine and provided with a pin or pins, of levers likewise pivoted to the stationary frame of the machine and engaging with the said pin or pins for swinging and stopping the swinging toothed segment, of toggle-levers controlling the movement of the said swinging and stopping levers, of frames suspended from the toggle-levers, each of the said frames being actuated by the keys corresponding to one and the same longitudinal row of types of the type-cylinder, and of means for controlling the turning movement of the type-cylinder by the said swinging segment.

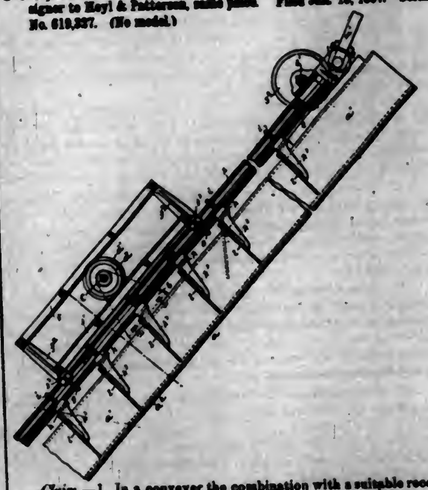
9. In a type-writing machine, in which the types are arranged in a plurality of circular sections and of longitudinal rows on the surface of a type-cylinder, the combination of a swinging lever, pivoted to the stationary frame of the machine and provided with a pin or pins, of levers likewise pivoted to the stationary frame of the machine and engaging with the said pin or pins for swinging and stopping the swinging lever, of toggle-levers controlling the movement of the said swinging and stopping levers, of frames suspended from the toggle-levers, each of the said frames being actuated by the keys corresponding to one and the same circular section of the types of the type-cylinder, and of means for controlling the longitudinal shifting movement of the type-cylinder.

10. In a type-writing machine, in which the types are arranged in a plurality of circular sections and of longitudinal rows on the surface of a type-cylinder, the combination of a swinging frame carrying the type cylinder and an adjustable stop for stopping the upward-swinging movement of the type-cylinder at different points.

605,620. OVERHEAD CAR OR LIKE RECEPTACLE. ALFRED M. ACKLIN, Pittsburg, Pa., assignor to Heyl & Patterson, same place. Filed Jan. 15, 1897. Serial No. 619,236. (No model.)

Claim.—1. In overhead cars and like receptacles, the combination with a suitable receptacle, of a downwardly-opening door, a rocking shaft mounted on said receptacle, a toggle connected to said door, and connections between said shaft and said toggle, substantially as set forth.

2. In overhead cars and like receptacles, the combination with a suitable receptacle, of a downwardly-swinging door, a rocking shaft mounted on said receptacle, a trip-lever mounted on said shaft, a weight on the lower end of said trip-lever, a toggle-joint connected to said door, and connections between said shaft and said toggle-joint, substantially as set forth.



3. In overhead cars and like receptacles, the combination with a suitable receptacle, of a downwardly-opening door, a rocking shaft mounted on said receptacle, an arm on said shaft, and connections between said arm and said door, the upper end of said arm being normally beyond the center of said shaft, substantially as set forth.

4. In overhead cars and like receptacles, the combination with a suitable receptacle, of a downwardly-opening door, a rocking shaft mounted on said receptacle, a trip-lever mounted on said shaft, an arm on said shaft, a toggle connected to said door, connections between said arm and said toggle, the upper end of said arm being normally beyond the center of said shaft, substantially as set forth.

5. In overhead cars and like receptacles, the combination with a suitable receptacle, of a downwardly-swinging door, a rocking shaft mounted on said receptacle, a trip-lever mounted on said shaft, an arm on said shaft, a bent lever pivoted to the upper end of said arm, a toggle connected to the lower end of said bent lever and to said door, the upper end of said arm being normally beyond the center of said shaft, substantially as set forth.

6. In overhead cars and like receptacles, the combination with an overhead beam, of a trolley moving thereon, a receptacle suspended from said trolley, a downwardly-swinging door, a rocking shaft mounted on said receptacle, a trip-lever on said shaft, connections between said shaft and said door and a trip on said overhead beam in the path of said trip-lever, substantially as set forth.

605,621. CONVEYER. ALFRED M. ACKLIN, Pittsburg, Pa., assignor to Heyl & Patterson, same place. Filed Jan. 15, 1897. Serial No. 619,237. (No model.)

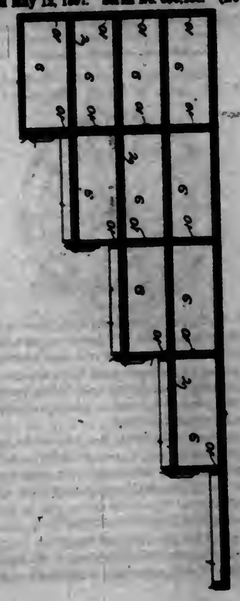
Claim.—1. In a conveyer the combination with a suitable receptacle, of a reciprocating bar, a U-bolt engaging said bar, a flight-frame secured to said U-bolt, nuts engaging the free ends of said U-bolt to hold said flight-frame thereon, a swinging flight on said flight-frame, said flight being supported against backward movement, substantially as set forth.

2. In a conveyer the combination with a suitable receptacle, of a reciprocating bar having a rounded contour, a U-bolt engaging the rounded portion of said bar, a flight-frame secured to said U-bolt, nuts engaging the free ends of said U-bolt to hold said flight-frame thereon, said flight-frame having a concave recess with which said reciprocating bar engages, a swinging flight on said flight-frame, said flight being supported against backward movement, substantially as set forth.

3. In a conveyer, the combination with a suitable receptacle of a reciprocating frame, flight-frames supported thereby, flights, hinges of flexible material connecting said flight-frames and flights, and means on said flight-frames for supporting said flights against backward movement, substantially as set forth.

4. In a conveyer, the combination with a suitable receptacle of a reciprocating bar, a flight-frame supported thereby, a flight, a hinge of flexible material connecting said flight-frame and flight, means on said flight-frame for supporting said flight against backward movement, and a projection on the rear face of said flight engaging the rear face of said flight frame to support said hinge, substantially as set forth.

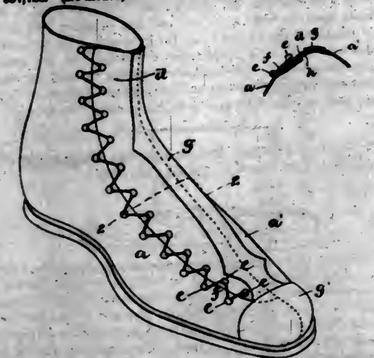
5. In a conveyer, the combination with a suitable receptacle of a reciprocating frame, a flight-frame supported thereby, a flight, a hinge of flexible material connecting said flight-frame and flight, means on said flight-frame for supporting said flight against backward movement, and a projection on the rear face of said flight engaging an inclined face of said flight frame to support said hinge, substantially as set forth.



6. In a conveyer, the combination with a suitable receptacle of a reciprocating frame, a flight-frame supported thereby, a flight, a hinge of flexible material connecting said flight-frame and flight, said flexible material being interposed between the rear face of said flight and a strip secured to said flight, said strip having a projection thereon adapted to engage with an inclined face on said flight-frame, substantially as set forth.

7. In a conveyer, the combination with a suitable receptacle, standards on said receptacle, a wheel journaled in said standards, a frame supported by said wheel, a bar supported thereby, swinging flights depending from said bar, said flights being supported against backward movement, and mechanism for reciprocating said bar, substantially as set forth.

8. In a conveyer, the combination with a suitable receptacle of standards on said receptacle, shaft in said standards, wheel on said shaft, said wheel having an annular rib on its periphery, a frame supported by said wheel, said frame having a slot into which the rib on said wheel enters, a bar supported by said frame, flights depending from said bar and entering said trough, said flights being supported against backward movement, and mechanism for reciprocating said frame; substantially as set forth.



9. In a conveyer, the combination with a suitable receptacle, of standards on said receptacle, a shaft in said standards, a wheel on said shaft, said wheel having an annular rib on its periphery, a frame supported by said wheel, said frame being composed of parallel bars, the upper of said parallel bars having a slot therein into which the rib on said wheel enters, the lower of said parallel bars having a like slot therein into which the rib on said wheel is adapted to enter, a bar supported by said frame, flights depending from said bar and entering said trough, said flights being supported against backward movement and mechanism for reciprocating said frame, substantially as set forth.

605,622. DISPLAY-STAND. WHITMORE M. BAKER, Waltham, Mass. Filed May 12, 1897. Serial No. 636,126. (No model.)

Claim.—A display-stand having a stepped series of horizontal slideways, vertical cross-pieces respectively located at and below the front ends of the respective steps and adapted to receive designation-bearing panels, the forward portions of each pair of slideways projecting outward beyond the forward ends and cross-piece of the pair of slideways next above, stock-containing trays sliding upon the rear-ward portions of said slideways behind the said cross-pieces, and display-trays resting upon said projecting portions of the said slideways in front of the cross-pieces and movable beneath said cross pieces as well as movable rearward and forward upon the said slideways to permit of withdrawal or insertion from the rear after removal of the stock-containing trays, substantially as described.

605,623. BOOT OR SHOE. CHARLES RALSON, Lynn, Mass., assignor of forty-nine one-hundredths to William W. Crocker, same place, and C. A. L. Brown, Boston, Mass. Filed May 22, 1897. Serial No. 637,723. (No model.)

Claim.—1. A boot or shoe upper comprising, first, the two side pieces *a a'* extending continuously from the toe to the heel and having their forward ends united by a short seam *b*, terminating below the instep portion, the said pieces being separated above said seam by an elongated opening *c*; and secondly, the flap or fly *d* attached to the piece *a'* along one edge of said opening and extending across the latter overlapping the corresponding edge of the piece *a*, and means for adjustably securing the flap to the piece *a* along the entire distance from the toe to the ankle.

2. A boot or shoe upper comprising, first, the two side pieces *a a'* extending continuously from the toe to the heel and having their forward ends united by a short seam *b*, terminating below the instep portion, the said pieces being separated above said seam by an elongated opening *c* extending over the instep portion and to the upper ends of the said side pieces; and secondly, the flap or fly *d* attached to the piece *a'* along one edge of said opening and extending across the latter overlapping the corresponding edge of the piece *a*, the said flap and the piece *a* having alternating studs or lacing-engaging projections whereby they may be adjustably connected along the entire length of the opening *c* by a lacing-cord.

3. A boot or shoe upper comprising, first, the two side pieces *a a'* extending continuously from the toe to the heel and having their forward ends united by a short seam *b*, terminating below the instep portion, the said pieces being separated above said seam by an elongated opening *c* extending over the instep portion and to the upper ends of said side pieces; and secondly, the flap or fly *d* attached to the piece *a'* along one edge of said opening and extending across the latter overlapping the corresponding edge of the piece *a*, said flap having a lining of dust-excluding material such as chamois skin arranged to bear on the outer surface of the piece *a*, and means for adjustably securing the flap to the piece *a*.

605,624. CAR-COUPLING. JOHN F. BALL, Jr., Turtle Creek, W. Va. Filed Dec. 20, 1897. Serial No. 662,638. (No model.)

Claim.—1. In a car-coupling, the combination of a draw-head, a lever fulcrumed at its rear end on the draw-head, a coupling-pin connected with the lever at a point between the ends of the latter, and a link provided between its ends with a lug or projection ar-

ranged to engage and lift the lever, said link being provided at its ends beyond the lug with an opening adapted to receive the coupling-pin, substantially as described.

2. In a car-coupling, the combination of a draw-head, a lever fulcrumed at its rear end on the draw-head, a coupling pin connected with the lever at a point between the ends thereof, and a link provided between its ends with a beveled lug arranged to lift the lever and interlocking with the front end thereof, said link being provided at its end beyond the lug, with an opening adapted to receive the coupling-pin, substantially as described.

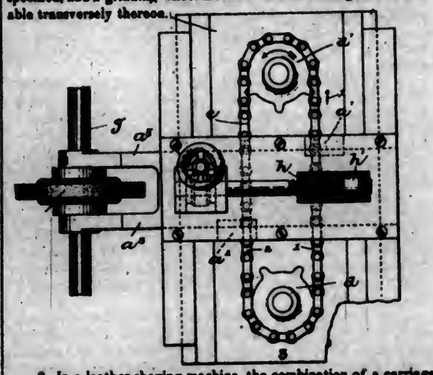
3. In a car-coupling, the combination of a draw-head, a lever fulcrumed at its rear end on the draw-head and provided at its front end with a depending hook, a coupling-pin connected with the lever at a point between the ends thereof, and a link provided with a beveled lug adapted to raise the lever and engaging the hook, said link being provided beyond the lug between the same and its end with a perforation to receive the coupling-pin, substantially as described.

4. In a car-coupling, the combination of a draw-head, a lever fulcrumed upon the same at its rear end and provided with an upwardly-extending arm having a lug, the front end of the lever being provided with a hook, a coupling-pin connected with the lever, a spring mounted on the draw-head and engaging the said lug, and a link provided with perforations and having lugs adapted to engage the said hook, substantially as and for the purpose described.

605,625. AWNING. EDWARD BILLSBURY, Grand Rapids, Mich. Filed Oct. 4, 1897. Serial No. 654,052. (No model.)

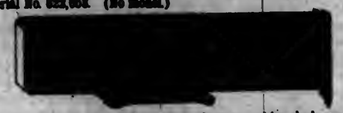
Claim.—1. In a window-awning, rods secured, vertically, to the window-frame, slides upon said rods, an arm projecting out from said slide to support the awning, arms projecting back from the slides to engage projections on the frame to actuate the arm D, said arms pivoted in the slides so that they may pass the projections when the awning is lowered and projections on the frame, substantially as and for the purpose set forth.

2. In a window-awning, rods secured, vertically, to the frame, projections on the window-frame, slides upon said rods, arms pivoted to said slides, a covering on said arms and extending the length of the window, cords for manipulating said awning, one end of which is secured at the ends of the arms to fold the awning before raising it and the other end in convenient reach of the operator, rings for guiding the awning on the rods, and a cleat inserted at the line of folding to hold the awning to position along this line, substantially as and for the purpose set forth.



605,626. REMOVABLE BICYCLE-HANDLE. JOHN C. BLANCHARD, Jr., Hyde Park, Mass. Filed Mar. 31, 1897. Serial No. 630,057. (No model.)

Claim.—A bicycle handle complete as a new article of manufacture, and comprising a support in the form of a tubular socket extending from end to end of the handle, said support having adjacent to but slightly removed from each end thereof an inclosing ring, material surrounding said support and retained by said inclosing rings suitable to be grasped by the hand, said support having at each end beyond said rings a tapered threaded portion, and end pieces interiorly threaded and correspondingly tapered to fit over the said threaded ends of the support, one of said end pieces being ring-like, and the other of said end pieces being closed to constitute the free end of the handle when the latter is secured in place on a handle-bar, substantially as described.



605,627. KNIFE-SHARPENING MECHANISM FOR LEATHER-SHAVING MACHINES. JOHN BOYLE, Peabody, Mass. Filed Mar. 11, 1897. Serial No. 626,904. (No model.)

Claim.—1. In a leather shaving machine, the combination of an endless chain provided with a lug or projection, horizontal sprocket-wheels engaged with said chain and dividing the same into two parallel straight reaches, means for rotating one of said wheels to drive the chain continuously in one direction, a carriage mounted to slide on guides and having two abutments on its under side located in the same horizontal plane, one of said abutments being arranged in operative relation to one reach of the chain, and the other being arranged in operative relation to the other reach of the chain, for the purpose specified, and a grinding-wheel mounted on said carriage and adjustable transversely thereon.

2. In a leather-shaving machine, the combination of a carriage mounted to slide on guides and having two abutments located in the same horizontal plane on its under side, an endless chain provided with a lug or projection adapted to alternately engage the said abutments to reciprocate the carriage, means for driving said chain continuously in one direction, a slide mounted transversely of the carriage in suitable guides thereon, a grinding-wheel carried by said slide, and means for adjusting said slide in its guides.

605,628. BICYCLE-KEEPER. ROBERT D. BRADLEY, Chicago, Ill., assignor of one-half to Frank X. Mudd, same place. Filed Feb. 8, 1897. Serial No. 622,662. (No model.)

Claim.—As a new article of manufacture, a bicycle-keeper comprising two slotted plates each of which is substantially L-shaped in cross section and adapted to be secured to an upright to provide a recess to receive a portion of the wheel rim and tire, a staple on one of the plates adjacent to the slot therein, a link-hasp on said staple and adapted to be passed through the slots in both plates to secure the wheel in the recess, and locking means for said hasp, substantially as described.

605,629. CIRCLE-CYCLE. EDWARD I BRANHAM, Richmond, Va. Filed Sept. 17, 1897. Serial No. 651,906. (No model.)

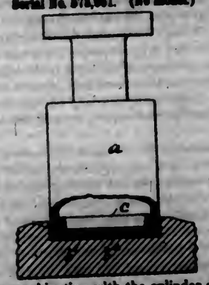
Claim.—1. In an apparatus as described, the combination with the turn-wheel, the post and the overhead support secured to and rotatable with the turn-wheel, the radial arms and the wheeled frames, of the hanger members having springs at their upper end connected to the overhead support, their lower ends being connected to the radial arms and provided with tension devices, all substantially as shown and for the purposes described.

2. In an apparatus as described, the combination with the turn-wheel and a wheeled carriage or bicycle, of radial arms arranged in series of three secured at their inner end to the turn-wheel, the ends of the outer arms being detachably connected with the front and rear axles of the carriage or frame, the center one to the top of such frame, and spanners connecting the two outer or bottom arms, substantially as shown and for the purposes described.

3. An apparatus as described, consisting of the central post the top of which is provided with a support, the base of said post having

rotatably secured thereon a turn-wheel, radial arms, arranged in series, having one of their ends secured to said turn-wheel, their other ends being attached to vehicles, a detachable spanner connecting the outer arms of each series, a separate cable connecting the several series, and spring-hangers attached to the said support at the top of the central post adapted to form supports for the said radial arms.

4. An apparatus as described, consisting of the central post, the top of which is provided with an apertured head, the base of said post being provided with a turn-wheel, radial arms attached to said turn-wheel, and means for supporting said radial arms, consisting of hangers having one of their ends attached to the said radial arms, their other ends being provided with springs adapted to be hooked within the said apertures in the said head at the top of the central post.

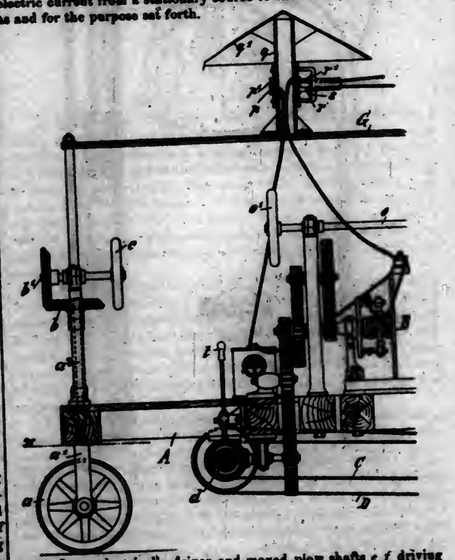


5. An apparatus as described, consisting of the central post, the top of which is provided with a circular head provided with apertures, the base of said post having rotatably mounted thereon a turn-wheel, radial arms attached to the said turn-wheel, their outer ends being attached to suitable vehicles, said radial arms being arranged in series and provided with detachable braces, cables connecting each of said series to the other, and hangers having one of their ends secured to said radial arms, their other ends being provided with a spring adapted to be hooked within the said supporting-head.

6. An apparatus as described, consisting of a central post, the top of which is provided with an annular supporting-head having apertures therein, the base of said post being provided with a turn-wheel, radial arms connected to said turn-wheel, said radial arms being arranged in series of three, detachable braces for said radial arms, and pendent hangers provided with yoked ends adapted to support the said radial arms.

7. An apparatus as described, consisting of a central post the top of which is provided with an annular head having apertures therein, the base of said post being provided with a turn-wheel, radial arms connected to said turn-wheel, braces detachably secured to said radial arms, and hangers having one of their ends provided with yokes adapted to be attached to the said radial arms their other ends being provided with a spring having a hooked end adapted to be hooked with the said apertures in the said annular head.

8. An apparatus as described, consisting of the central post having a turn-wheel at its base and a supporting-head at its top, said supporting-head being provided with apertures, radial arms connected to the said turn-wheel, said radial arms being arranged in series of three, a detachable brace for each series of radial arms, a yielding cable adapted to connect one series to the other, said pendent hangers, the upper ends of which are provided with springs adapted to be hooked within the said apertures in the said supporting-head, their lower ends being provided with yoke-hangers adapted to be attached to the outer members of each of said radial arms.



605,630. HYDRAULIC JACK. FRANK C. RECORD, Dayton, Ohio, assignor of one half to the Joyce-Cridland Company, same place. Filed Feb. 10, 1896. Serial No. 578,661. (No model.)

Claim.—The combination with the cylinder of a hydraulic jack having a removable base, of a continuous metallic cup packing covering the base within the cylinder, and fitting against the inner surface of the cylinder by a rim or flange having its interior inclined, and a continuous expanding plug of harder metal having a reversely-inclined periphery adapted to partially descend under hydraulic pressure to expand the cup-rim against the cylinder and to force the packed end of the cylinder laterally against its base-support, whereby leakage in any direction is prevented and the cylinder more firmly held in its seat, substantially as specified.

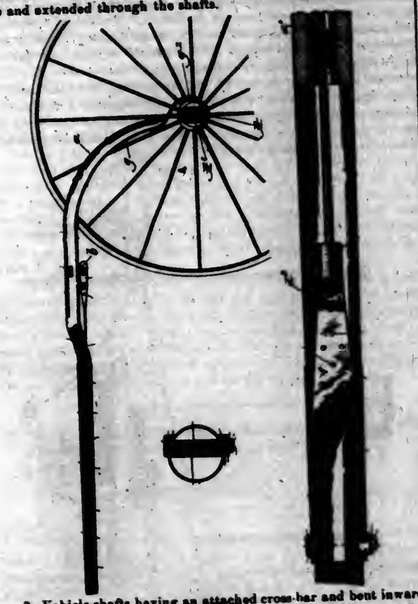
605,631. ELECTRICALLY DRIVEN AND MOVED PLOW. RUDOLF DALLMANN, Bromnitz, Germany, assignor to The Firm of T. Conrad, same place. Filed Oct. 9, 1897. Serial No. 654,673. (No model.)

Claim.—1. In an electrically driven and moved plow a guidable plow-carriage A, a plurality of shafts *e f* arranged behind each other in the rear part of said carriage, frames F F' pendulously suspended and devices for adjusting and securing them, shafts *g* lodged in said frames so as to be prevented from coaxial shifting and bearing firmly attached to their lower end conical plow-screws E, a contrivance for moving forwardly and backwardly plow-carriage A, which bears all parts of the plow, an electromotor B driving said carriage and actuating the plow-screws and means for conveying the electric current from a stationary source to the motor, substantially as and for the purpose set forth.

2. In an electrically driven and moved plow shafts *e f* driving conical plow-screws in the rear part, and principal driving-shafts *d*, actuated by an electric motor B by means of a communicator in the fore part of the plow-carriage A, belt-gearings D D' transmitting the movement from said driving-shafts *d* unto shafts *e f* and another belt-gearing *b* transmitting the movement from *d* to the carriage's rear axis and finally means for reversing principal driving-shaft *d*, substantially as and for the purpose described.

3. In an electrically driven and moved plow shafts *e f*, arranged behind each other and driving a plurality of conical plow-screws E, frames F, pendulously suspended at these shafts and coupled by guide-bars *i*, plow-screws E at the lower end of driving-shafts *g*, the latter being lodged at said frames F in such a manner as to be prevented from coaxial shifting and means for adjusting and securing said frames, substantially as and for the purpose described.

4. In an electrically driven and moved plow frames F in which are lodged a plurality of plow screw-shafts *g*, guide-bars *i* for connecting said frames with each other and means for adjusting and securing them, consisting in a vertical screw-spindle *k*, lodged at the framing of the plow-carriage so as to be prevented from coaxial shifting, a screw-nut *l* traveling upon the same and being secured against turning round a guide *m* connecting said nut with the foremost frame F, a shaft *o* having a hand-wheel *o'* at its upper end and a pair of conical wheels *n* for transmitting the movement from said shaft *o* to screw-spindle *k*, substantially as and for the purpose set forth.



5. In an electrically driven and moved plow a roof G protecting plow-carriage A, a hollow post *q* secured upon G and covered by another smaller roof *q'*, two rings *p p'* serving as sliding contacts and being disposed on pole *q*, springs *r r'* sliding upon said rings and acting as sliding brushes and finally a bow S, turning loosely around pole *q* and bearing these sliding brushes *r r'* to which the conducting-wires are fastened, substantially as and for the purpose set forth.

605,632. VEHICLE-SHAFT. WILBUR S. DAVIS, Concord, Mass. Filed Nov. 6, 1897. Serial No. 657,613. (No model.)

Claim.—1. Vehicle-shafts having longitudinal bores through their straight portions, draft members concealed therein, and a whiffletree to which the rear exposed ends of said draft members are attached.

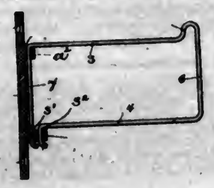
2. The combination with vehicle-shafts having a cross bar, and a

whiffletree mounted thereon, of draft members attached to the whiffletree and extended through the shafts.

3. Vehicle-shafts having an attached cross-bar and bent inward and downward in front of said bar, attaching means mounted on the cross-bar in the plane of the straight outer portions of the shafts extended from the inward bends, and draft members connected with said attaching means and extended through longitudinal bores in the straight portions of the shafts.

4. Vehicle-shafts having longitudinal bores in their straight portions and open at their tips, draft members permanently retained in the shafts and extended through the open tips, and an antifriction-bearing located at or near the tip of each shaft, for the adjacent portion of the draft member.

5. Vehicle-shafts having an attached cross-bar, a whiffletree mounted thereon, said shafts being bent in front of the cross-bar to bring their straight portions into the plane of the whiffletree, and permanent draft members attached to the whiffletree and led through the straight portions of the shafts.



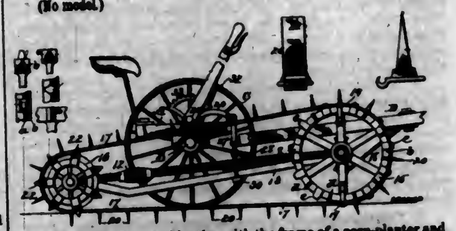
6. Vehicle-shafts comprising wooden body portions having straight, longitudinally-bored forward ends, draft members passed through the said straight portions of the shafts, and a metallic envelop or sheath for the straight portion of each shaft.

7. Vehicle-shafts, draft members extended therethrough and having laterally-flexible extensions at their front ends to be attached to the harness, antifriction-bearings for said extensions mounted on the shafts, and means to secure the rear ends of the draft members to the vehicle.

8. Vehicle-shafts downturned at their rear ends and rigidly connected by a cross-bar, said shafts being bent inward and downwardly between said bar and the straight front ends of the shafts, the shafts having longitudinal openings in their straight portions.

9. Vehicle-shafts having straight, longitudinally-bored portions, and draft-members extended therethrough and exposed at their front and rear ends respectively.

605,688. CLOTHES-HANGER. ERNEST J. DERAGON, Fitchburg, Mass. Filed July 26, 1897. Serial No. 645,973. (No model.)



Claim.—1. A clothes-hanger comprising a socketed holder adapted for attachment to a fixed support, and a wire frame bent to form two substantially parallel arms, a bar connecting the outer ends of said arms, and pintles at the inner ends of the arms engaged with sockets in the holder, the said pintles being out of alinement with each other.

2. A clothes-hanger comprising a socketed holder adapted for attachment to a fixed support, and a wire frame bent to form two substantially parallel arms, a guard at the outer end of the upper arm, a bar connecting the said guard with the outer end of the lower arm, and pintles at the inner ends of the arms engaged with sockets in the holder, the said pintles being out of alinement with each other.

3. A clothes-hanger comprising a plate adapted for attachment to a fixed support and provided with an upper flange having a single row of sockets and a lower flange having two rows of sockets and a series of two-armed wire frames, the upper arms having elongated pintles extending through the sockets in the upper flange and the inner sockets in the lower flange, while the lower arms have shorter pintles extending through the outer sockets in the lower flange, in front of the said elongated pintles.

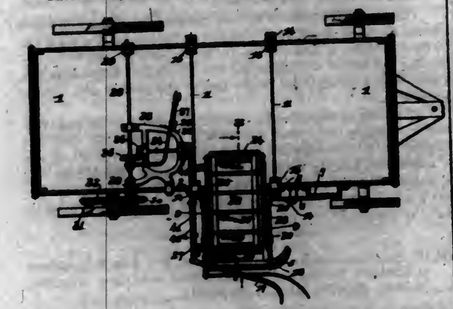
605,684. CHECK-ROWER FOR CORN-PLANTERS. WILBUR O. DURYEA, Morning Sun, Iowa. Filed Nov. 12, 1897. Serial No. 658,294. (No model.)

Claim.—1. The combination with the frame of a corn-planter and a tongue, of a frame connected with said tongue, wheels carried at each side of said last-mentioned frame, a chain passing over each pair of wheels and adapted to engage the ground, markers on one wheel of each pair, and means for raising said last-mentioned frame, substantially as set forth.

2. The combination with the frame and tongue of a corn-planter, of a movable frame attached to the tongue, wheels carried by said movable frame, markers carried by one of said wheels, a chain passing over said wheels and adapted to engage the ground, a crank-shaft mounted on the frame of the planter, a rod or link connected with said crank-shaft, chains connecting said rod or link with said movable frame, and an operating-lever secured to said crank-shaft, substantially as set forth.

3. The combination with the frame and tongue of a corn-planter, of a screw passing through said tongue and having an eye or loop at its upper end, a casting secured to the lower end of said screw, a revoluble shaft having a central bearing in said casting, lateral bearings for said shaft, a trans-rod secured at its ends to said lateral bearings and passing through the eye or loop on the screw, wheels carried by said shaft and markers carried by said wheels, substantially as set forth.

4. The combination with the frame and tongue of a corn-planter, of a casting secured to said tongue, a revoluble shaft having a central bearing in said casting, lateral bearings for said shaft, a fixed shaft, bearings therefor, adjustable connections between the lateral bearings for the revoluble shaft and the bearings of the fixed shaft, wheels secured to the revoluble shaft, markers on said wheels, wheels mounted loosely on the fixed shaft, chains passing over said wheels and means for causing said chains to engage the ground, substantially as set forth.



5. The combination with the frame and tongue of a corn-planter, of a casting secured to the tongue, a revoluble shaft having a central bearing in said casting, lateral bearings for said shaft, a fixed shaft, lateral bearings for the fixed shaft, connections between said lateral bearings, and rods or bars connected at one end to said casting and at the other end to said fixed shaft, wheels mounted loosely on the fixed shaft, wheels secured to the revoluble shaft and carrying markers and chains passing over said wheels and adapted to engage the ground, substantially as set forth.

6. In a check-rower for corn-planters, the combination with suitable framework, of two wheels carried by said framework, one of said wheels having a rim triangular in cross-section so as to present inclined faces, sprocket-teeth projecting from said rim, enlargements between said sprocket-teeth and having beveled or inclined faces, a sprocket-chain passing over said wheels, and lugs projecting from links of said chain and adapted to enter the ground, substantially as and for the purpose set forth.

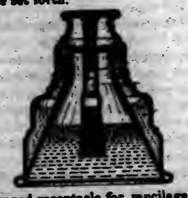
7. In a check-rower for corn-planters, the combination with suitable framework, of two wheels carried by said framework, each wheel having a rim provided with inclined or divergent faces, a chain passing over said wheels, and lugs on said chain to engage the ground, substantially as set forth.

8. In a check-rower for corn-planters, the combination with suitable framework, of wheels carried thereby, one of said wheels carrying markers, a chain passing over said wheels, each wheel having a rim made triangular in cross-section, and U-shaped projections on one of said wheels and adapted to guide the chain, substantially as set forth.

605,685. CORN-HEADER. CHARLES E. BOKLAGE, Vliet, Kans. Filed Jan. 20, 1897. Serial No. 619,948. (No model.)

Claim.—1. The combination with a wagon-body, and a harvesting attachment, of the following means for detachably connecting the harvesting attachment with the wagon-body, consisting of plates, fastenings for securing the harvesting attachment to the plates, vertical rods threaded at their upper ends and having a series of openings at their lower ends, tie-rods connecting the lower ends of the vertical rods and passing through corresponding openings therein, angle-plates placed upon the upper ends of the vertical rods and having their vertical portions engaging with the inner faces of the side pieces of the wagon-body, and rods connecting oppositely-disposed angle-plates, substantially as set forth.

2. In a corn-harvester, the combination of longitudinal cutters having their front ends curving outwardly, and longitudinal guide-bars placed below the cutters and spaced apart, forming a passage for the stalks, and having their front ends curving forwardly, outwardly and downwardly to gather in leaning stalks, and having a space between their rear ends, substantially as set forth.



3. In a harvesting mechanism, the combination of a cutting apparatus comprising an oscillating part, an elevator for receiving the grain as cut and directing it into a receptacle, actuating mechanism, and a single pitman for transmitting motion from the actuating mechanism to the elevator and cutting apparatus for simultaneously operating each, substantially in the manner specified.

4. In a harvesting mechanism, the combination of a cutting apparatus comprising an oscillating part, an elevator for conveying the grain to a receptacle, actuating mechanism, a pitman for transmitting motion from the actuating mechanism to the cutting apparatus, an extension having pivotal connection with the pitman, and a ratchet mechanism between the pivoted extension and elevator, whereby the latter is operated simultaneously with the cutting apparatus by means of the same pitman, substantially as set forth.

5. In a harvesting mechanism, the combination of the cutting apparatus, an elevator for conveying the grain to a receptacle, a ratchet-wheel applied to a journal of the elevator, actuating mechanism, a pitman for transmitting motion from the actuating mechanism to the cutting apparatus, an extension having pivotal connection with the pitman and provided with a toothed portion for direct engagement with the said ratchet-wheel, a pivoted arm applied to the pivoted extension and having a toothed portion to engage with the said ratchet-wheel and move it when the pivoted extension is returning to a normal position, and a spring interposed between the pivoted arm and extension, substantially as set forth.

605,686. MUCILAGE-BOTTLE. THOMAS A. FINK, Paris, Canada, assignor to John Lindsay, same place. Filed Sept. 18, 1897. Serial No. 652,152. (No model.) Patented in Canada June 26, 1897, No. 56,482.

Claim.—1. In an improved receptacle for mucilage and like material, a hollow cap-piece having its top portion forming an interior socket or seat, and a flat disk corresponding to the top portion of said cap and coextensive in area therewith, said disk being seated and secured in the interior socket of the cap and provided with a depending shank or stem adapted to carry a brush, substantially as and for the purpose set forth.

2. In an improved receptacle for mucilage and like material, a hollow cap-piece having an exterior flat and unobstructed top portion of sufficient area to form a supporting-base when the cap is inverted, and provided with an interior socket or seat, said cap-piece carrying an interiorly projecting and depending brush, sustained from a head portion fitted in said interior socket or seat, whereby the cap-piece may be inverted so that its exterior flat and smooth top face is adapted to rest upon any corresponding surface and sustain the projecting brush in upright position, substantially as and for the purpose set forth.

3. In an improved receptacle for mucilage and like material, a brush member comprising a flat disk top portion having a flat and unobstructed top surface without projections and of sufficient area to form a supporting-base when the brush member is inverted, said cap-piece being provided with an interior socket or seat, and a stem depending from a head portion fitted in said interior socket or seat of said top disk and carrying a brush, substantially as and for the purpose set forth.

4. In an improved receptacle for mucilage and like material, a brush member, comprising a flat top disk of sufficient area to form a supporting-base when the brush member is inverted, said disk carrying a depending tapering stem mounted upon a head portion seated in an interior socket or seat in the top disk, in combination with a brush having a cylindrical portion adapted to receive and bind upon said tapering stem, substantially as and for the purpose set forth.

5. An improved receptacle for mucilage and like material, comprising a hollow cap-piece having an interior socket or seat in its top portion and a flat and unobstructed exterior top surface of sufficient area to form a supporting-base when the cap is inverted, and a disk corresponding to said flat top portion of the cap and of coextensive area therewith, said disk being seated and secured within the socket of the cap and provided with a depending stem carrying a brush, substantially as and for the purpose set forth.

6. An improved receptacle for mucilage and like material, comprising a hollow cap-piece having an interior socket in its top portion and a flat and unobstructed top surface of sufficient area to form a supporting-base when the cap-piece is inverted, a disk corresponding to said flat top portion of the cap and of coextensive area therewith, said disk being seated and secured in the interior socket of the cap and provided with a depending tapering stem, and a brush having a cylindrical stem or portion receiving and binding upon said tapering stem, substantially as and for the purpose set forth.

7. In an improved receptacle for mucilage and like material, a hollow cap piece having an imperforate top wall with an exterior flat and unobstructed top surface of sufficient area to form a supporting-base when the cap is inverted, said exterior flat top surface of the hollow cap-piece having no projections or obstructions extending from or beyond the exterior surface of the flat disk forming its top wall, and a brush member interiorly carried within said hollow cap-piece and having its top portion within the plane of the flat disk forming the top wall of the cap-piece and its lower portion projecting from the latter, substantially as and for the purpose set forth.

8. An improved receptacle for mucilage and like material, comprising a body portion having a neck-flange at the base of which is formed an annular depression or seat, a cap-piece having a depending flange with an edge corresponding to and fitting said depression and provided with an interior socket in its top portion, and a disk corresponding to said top portion of the cap and coextensive in area therewith and seated and secured in said interior socket, said disk being provided with a depending stem carrying a brush, substantially as and for the purpose set forth.

9. An improved receptacle for mucilage and like material, comprising a body portion having a neck-flange at the base of which is formed an annular depression or seat, a cap-piece having a depending flange with an edge corresponding to and fitting said depression or seat and provided with an interior socket or seat at its top, the exterior top surface of said cap being flat and unobstructed and of sufficient area to form a supporting-base when the cap is inverted, a flat

disk corresponding to said flat top portion of the cap and coextensive in area therewith and seated and secured in the interior socket thereof, said disk having a depending tapering stem, and a brush having a cylindrical portion or stem receiving and binding upon said tapering stem of the disk, substantially as and for the purpose set forth.

10. An improved receptacle for mucilage and like material, comprising a body portion having a neck-flange at the base of which is formed an annular depression, a hollow cap-piece having a depending flange provided with a beaded edge fitting said depression and with an exteriorly flat and unobstructed top face, a disk corresponding to and carried in the flat top portion of the cap-piece and having a tapering stem with a rounded end, and a brush having a cylindrical portion or stem receiving said tapered and rounded stem, substantially as and for the purpose set forth.

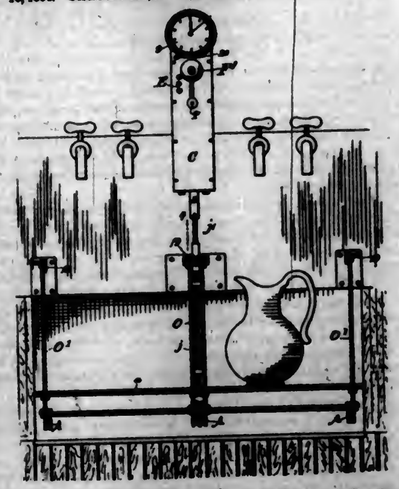
11. An improved receptacle for mucilage and like material, comprising a receptacle, a casing inclosing the body of said receptacle and forming a water-tight compartment open at its top with respect to said inclosed receptacle, a hollow cap-piece fitting said exterior casing and having an interior socket or seat at its top, and a disk corresponding to and fitting the top portion of the cap-piece and secured in said interior seat, said disk being provided with a depending stem carrying a brush, substantially as and for the purpose set forth.

12. An improved receptacle for mucilage and like material, comprising a receptacle, a casing inclosing the body of said receptacle and forming a water-tight compartment and open at its top with respect to said inclosed receptacle, said casing having a neck-flange, a hollow cap-piece having a depending flange fitting said neck-flange and interiorly provided with a socket or seat in its top portion and having a flat and unobstructed exterior top face of sufficient area to form a supporting-base when the cap-piece is inverted, and a disk corresponding to the free top portion of the cap and coextensive in area therewith, said disk being seated and secured in the interior socket of the cap and provided with a depending stem carrying a brush, substantially as and for the purpose set forth.

13. An improved receptacle for mucilage and like material, comprising a receptacle, a casing inclosing the body of said receptacle and forming a water tight compartment and open at its top with respect to said inclosed receptacle, said casing being provided with a neck-flange at the base of which is formed an annular depression or seat, a hollow cap-piece having a depending flange with an edge conforming to and fitting said annular depression or seat, said cap-piece being provided with an interior socket at its top portion and with a flat and unobstructed exterior face of sufficient area to form a supporting-base when the cap is inverted, and a disk corresponding to said flat top portion of the cap and coextensive in area therewith and seated and secured in said interior socket, said disk being provided with a depending stem carrying a brush, substantially as and for the purpose set forth.

14. An improved receptacle for mucilage and like material, comprising a receptacle having a neck-flange provided with an inwardly and diagonally projecting annular flange, a casing inclosing the body of said receptacle and forming a water-tight compartment and open at its top with respect to said inclosed receptacle, said casing being provided with a neck-flange at the base of which is formed an annular depression or seat, a hollow cap-piece having a depending flange fitting the neck-flange of the casing and provided with an edge conforming to and fitting said annular depression or seat, said cap-piece being provided with an interior socket at its top portion and with a smooth and unobstructed exterior top face of sufficient area to form a supporting-base when the cap is inverted, and a disk corresponding to the flat top portion of the cap and coextensive in area therewith, said disk being seated and secured in the interior socket of the cap and provided with a depending stem carrying a brush, substantially as and for the purpose set forth.

15. An improved receptacle for mucilage and like material, comprising a receptacle having a neck-flange provided with an interiorly and diagonally projecting annular flange, a casing inclosing the body of said receptacle and forming a water-tight compartment and open at its top with respect to said inclosed receptacle, said casing being provided with a neck-flange at the base of which is formed an annular depression or seat, a hollow cap having a depending flange fitting the neck-flange of the casing and provided with an edge conforming to and fitting said annular depression or seat, said cap being provided with an interior socket at its top portion and with a flat and unobstructed exterior top face of sufficient area to form a supporting-base when the cap is inverted, a disk corresponding to said flat top portion of the cap and coextensive in area therewith, said disk being seated and secured in the interior socket of the cap and provided with a tapering depending stem, and a brush having a cylindrical portion or stem receiving and binding upon said tapering stem of the disk, substantially as and for the purpose set forth.



16. An improved receptacle for mucilage and like material, comprising a receptacle having a neck portion provided with an interiorly and diagonally projecting annular flange, a casing inclosing said receptacle and forming a water-tight compartment, said casing being provided with a neck-flange projecting with relation to the neck-flange of the inclosed receptacle and terminating below the top plane thereof, and a cap-piece having a depending flange fitting the neck-flange of the casing and forming a closure for the flanged projecting neck portion of the receptacle, said cap-piece carrying an interiorly-depending brush carried by a head portion seated in an interior socket or seat in the cap-piece and projecting within the flanged neck portion of the receptacle, substantially as and for the purpose set forth.

605,687. PROCESS OF MANUFACTURING CEMENT. HUGO GALLUSOWSKY, St. Louis, Mo., assignor, by mesne assignments, to the Lithosite Manufacturing Company, same place. Filed Oct. 14, 1897. Serial No. 655,113. (No specimens.)

Claim.—1. The herein-described process of making oxychlorid cement, the same consisting in initially heating chlorid of magnesium, or its equivalent, to drive off water, adding oxid of magnesium, reheating the chlorid of magnesium and the oxid of magnesium to a higher degree of heat, and finally mixing the product with oxid of magnesium.

2. The herein-described process of making cement, the same consisting in mixing oxalic acid or oxalate of ammonia with chlorid of magnesium, to neutralize the calcium chlorid present in the chlorid of magnesium, heating the mass to drive off water, then adding oxid of magnesium, and again heating the mass to a higher degree of heat, and finally grinding the product with oxid of magnesium, substantially as described.

605,688. SCALE. LOUIS HAGENBURGER, New York, N. Y., assignor to Edward F. Watkins and Lawson Bradford, same place. Filed Nov. 16, 1896. Serial No. 612,177. (No model.)

Claim.—1 A weighing apparatus comprising an indicating device, a support for the body to be weighed, a connection intermediate of said support and the indicating device made in two sections slidably connected to permit motion of the section in connection with the support without imparting motion to the indicating device, means for locking said sections together by hand, and means adapted to engage with the locking means for automatically unlocking the same when the weighed body is removed from the support, a stop for the section in connection with the indicating device for determining the zero position of the hand, a counter, and an operative connection between the rod-section in connection with the indicating device and said counter, substantially as described.

2. A weighing apparatus comprising an indicating device, a support for the body to be weighed, a connecting-rod intermediate of the support and the indicating device and made in two sections slidably connected to permit motion of the section in connection with the support without imparting motion to the indicating device, means for locking said sections together by hand, means adapted to engage with said locking means for automatically unlocking the same when the weighed body is removed from the support, a stop for the section in connection with the indicating device for determining the zero position of the hand, a counter, a sounding device, and operative connections between the rod-section in connection with the indicating device and said counter and sounding device, substantially as described.

3. A weighing apparatus comprising an indicating device, a support for the body to be weighed, a connecting-rod intermediate of the support and the indicating device and made in two sections slidably connected to permit motion of the section in connection with the support without imparting motion to the indicating device, means for locking said sections together by hand, means adapted to engage with said locking means for automatically unlocking the same when the weighed body is removed from the support, a stop for the section in connection with the indicating device for determining the zero position of the hand, a counter, a sounding device, and operative connections between the rod-section in connection with the indicating device and said counter and sounding device, substantially as described.

4. A weighing apparatus comprising an indicating device, a support for the body to be weighed, a connection intermediate of said support and the indicating device made in two sections slidably connected to permit motion of the section in connection with the support without imparting motion to the indicating device, means for locking said sections together by hand, means arranged across the path of said locking means for unlocking the same when the weighed body is removed from the support, a cross-head pivoted to the section in connection with the support, and springs attached to a fixed part of the apparatus and to said cross-head, substantially as described.

5. A weighing apparatus comprising an indicating device, a support for the body to be weighed, a connecting-rod intermediate of the support and the indicating device and made in two sections slidably connected to permit motion of the section in connection with the support without imparting motion to the indicating device, means for locking said sections and for automatically unlocking the same, and a stop for the section in connection with the indicating device for determining the zero position of the hand, substantially as described.

6. A weighing apparatus comprising an indicating device, a pan or platform, a connecting-rod intermediate of the pan or platform and the indicating device and made in sections slidably connected, and a locking and unlocking device for the rod-sections composed of a cam adapted to press the sections together, and a pawl adapted to engage with said cam on the descent of the connecting-rod, substantially as described.

7. A weighing apparatus comprising an indicating device, a pan or platform, a connecting-rod intermediate of the pan or platform and the indicating device and made in sections slidably connected, means for locking and unlocking said sections, a disk provided with sockets, a pin or pins adapted to be inserted in said sockets, a sounding device adapted to be engaged by said pins, and an operative connection between the upper rod-section and said disk, substantially as described.

605,639. BURIAL-CASKET. SAMUEL W. HERRELL, Bull Run, Tenn. Filed June 19, 1897. Serial No. 641,491. (No model.)

Claim.—1. A casket consisting of shells arranged one within the other and having a filling or core of plastic material, a protruding flange around the bottom of the casket, cross-bars united to the bottom and extended beneath said flange to reinforce the same, and handles fastened to said protruding flange, for the purposes described, substantially as set forth.

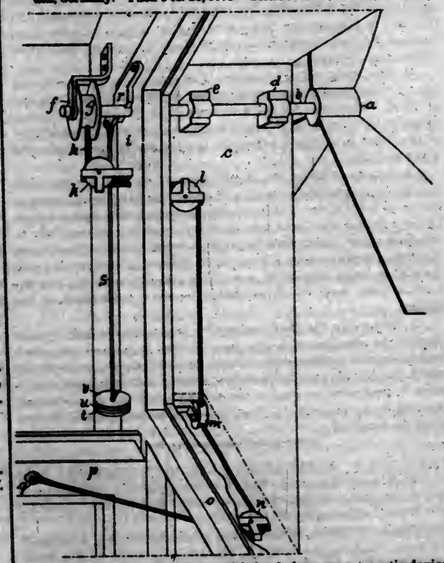
2. The combination of a casket having a protruding flange around the bottom thereof, the cross-bars united to said bottom and extended beneath said protruding flange, and handles passing through the flange and united to the ends of said cross-bars, for the purposes described, substantially as set forth.

605,640. PIPE-THIMBLE. LEWIS T. HOUGHTON and WILLARD H. BENTON, Worcester, Mass. Filed Aug. 6, 1897. Serial No. 647,167. (No model.)

Claim.—1. In a pipe-thimble composed of a sheet-metal cylinder and a sheet-metal collar-plate, the cylinder portion A having its end turned outward as a flat annular flange *a*, and the collar-plate B formed with the upward circular flange *b* adapted to fit the interior of said cylinder, said flanged parts matching upon each other, as shown, with the flanges *a* and *b*, together with the collar and cylinder-plates, forming a double-ply angle along the junction-line, and the parts secured in such connection by clench-points cut and turned up from the collar-plate and clenched over the edge of said annular flange, as shown and described.

2. In combination with a pipe thimble, the retaining wire or spring having the curved portion arranged around the side of the cylinder and supported thereon by suitable clips, and having ends that project laterally therefrom, substantially as and for the purpose set forth.

3. In a pipe-thimble, the combination, with two half-collar sections united by a slip-joint, and comprising the underlying part 1 having the lips *c*, and the overlying part 2 having the groove *d*, and adapted for support one upon the other; of the single spring-wire formed with the curved portion *f* and resilient projecting end portions 5, said spring-wire having its curved portion attached to the half-collar section representing the underlying part, for supporting the thimble, substantially as set forth.

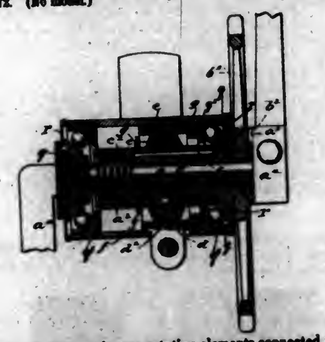


605,641. POLISHING-WHEEL. ALBERT KORTUM, Brooklyn, N. Y., assignor to the Straker & Levett & Loeb Company, New York, N. Y. Filed Dec. 21, 1897. Serial No. 662,846. (No model.)

Claim.—1. A polishing-wheel having a wooden core, a radially-extending polishing body secured to the core, and wooden clamping-rings fitted upon the ends of the core and surrounding the same, the grain of the clamping-rings running in a direction different from the grain of the core.

2. A polishing-wheel comprising a wooden core having reduced ends, a radially-extending polishing-body secured to the core by means of a waterproof cement, wooden clamping-rings fitted upon the reduced ends of the core, with the grain of the rings running in a direction different from the grain of the core.

605,642. AUTOMATIC WINDOW-CLOSER. EMIL KURASCH, Dresden, Germany. Filed Feb. 25, 1898. Serial No. 671,582. (No model.)



Claim.—1. In combination with a window, an automatic device for closing the same on the arising of a wind comprising a wind-wheel and operating connections therefrom to the window-sash whereby the movement of the wind-wheel effects the closing of the window, substantially as described.

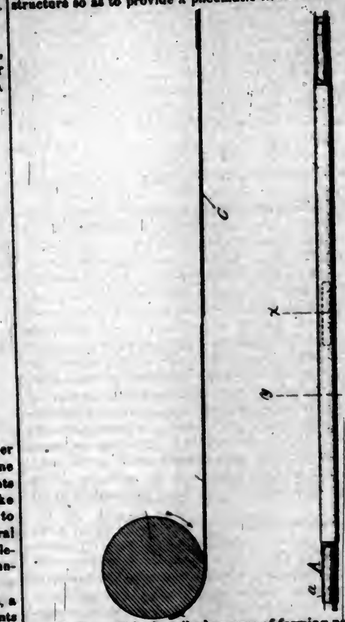
2. In combination, with a window, a wind-wheel, a drum carried

by the shaft thereof, a cord adapted to be wound on said drum and operatively connected with the window sash, and a brake to prevent the too free movement of said wind-wheel, substantially as described.

605,643. BACK-PEDALING BRAKE. WILLIAM A. LEGGO, Jr., Hartsdale, N. Y., assignor of one-fourth to the Long Island Rubber and Cycle Company, of New York. Filed May 11, 1896. Serial No. 590,972. (No model.)

Claim.—1. In a cycle, two rotating elements connected together by a screw-thread, whereby their relative movement will cause one of them to move laterally, in combination with two brake elements carried respectively by the two rotating elements, and a third brake element interposed between said two brake elements and adapted to be moved slightly in a lateral direction whereby the relative lateral movement of said rotating element will cause said third brake element to be clamped between the other two brake elements, substantially as described.

2. In a bicycle the combination of a crank-axle and cranks, a sprocket-wheel loosely mounted on the axle, interlocking abutments whereby the cranks and wheel will rotate together or differentially, at will, and a fixed screw-thread on the axle, a brake member engaging with said thread and adapted to rotate with the sprocket-wheel, but to move independently thereof to operate a brake, a drum and fixed strap surrounding the same for producing a constant friction, said brake member being arranged to engage with the drum to cause it to rotate with the sprocket-wheel and against the friction of the strap thereon.

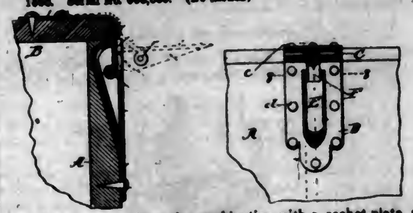


3. In a cycle, the combination of an axle, a sleeve thereon, carrying a sprocket-wheel, a brake member feathered to the sleeve and provided with a screw-thread, a corresponding thread on the axle, a second brake member and means for rotating the axle independently of the sleeve to a limited extent for the purpose of moving the first brake member.

4. In a cycle-brake, the combination of an axle, a sleeve surrounding it and normally rotating therewith, a sliding brake member feathered to the sleeve, a corresponding brake member, means whereby the axle and the sleeve may be caused to rotate differentially to a limited extent, and a screw-thread connection between the axle and the sliding brake member whereby such differential motion will cause the sliding brake member to move longitudinally upon the axle toward or away from its corresponding member, substantially as described.

5. In a cycle, the combination of a brake element held against rotation by attachment to the frame of the cycle, and two other brake elements rotating with a rotary part of the cycle and between which the first element is interposed, driving mechanism and mechanism whereby the reversal of the driving power will cause the two rotating brake elements to clamp the fixed brake element, substantially as described.

605,644. MANUFACTURE OF PNEUMATIC-TIRE TUBES. FRED W. MORGAN, Chicago, and ERNEST W. YOUNG, Austin, Ill., assignors to the Morgan & Wright, Chicago, Ill. Filed Mar. 10, 1896. Serial No. 573,231. (No model.)

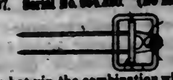


Claim.—1. The within-described process of forming pneumatic-tire tubes consisting essentially in the following steps, to wit: forming a strip of textile material and strips of rubber severally of less width than the strip of textile material; producing a composite fabric by applying the strips of rubber respectively to opposite sides of the strip of textile material, and respectively over different portions of the width of the latter so as to relatively alternate in position thereon; rolling up this composite fabric into tubular form by rolling a pole or mandrel over such composite fabric spread out upon a bed or table; removing such tubular structure from the mandrel and uniting its ends; and then molding and vulcanizing the endless tubular structure so as to provide a pneumatic-tire tube.

2. The within-described process of forming pneumatic-tire tubes consisting essentially in the following steps, to wit: forming a strip of textile material and strips of rubber severally of less width than the strip of textile material: producing a composite fabric by applying the strips of rubber respectively to opposite sides of the strip of textile material, and respectively over different portions of the width of the latter so as to relatively alternate in position thereon; rolling up this composite fabric into tubular form by rolling a pole or mandrel over such composite fabric spread out upon a bed or table; removing such tubular structure from the mandrel and uniting its ends; inflating this endless tubular structure thus formed by hypodermically injecting air therein; and then molding and vulcanizing this inflated tubular structure, so as to produce a pneumatic-tire tube.

3. An endless, annular pneumatic-tire tube comprising in its structure and characterized by a strip of textile material having upon one side a thin rubber strip extending from one of its longitudinal edges part way across its width, and having upon its opposite side a strip of rubber extending from one of its longitudinal edges part way across its width, the composite fabric thus formed being rolled into tubular form with contiguous tubular plies of textile material arranged between inner and outer plies or layers of rubber provided by the rubber strips on opposite sides of the strip of textile material, and the whole molded and vulcanized, substantially as described.

605,645. HASP-FASTENER. JOHN A. MOSHER, Chicago, Ill., assignor to the Adams & Westlake Company, of Illinois. Filed Jan. 26, 1898. Serial No. 668,089. (No model.)



Claim.—1. In a hasp the combination with a socket-plate, and a latch-piece adapted to hook into the recess of the socket-plate, of an attaching-plate having a spring-shank, and a link connecting the latch-piece with the attaching-plate.

2. In a hasp, the combination with a hinge-plate having a spring-shank, and a socket-plate having overhanging shoulders at its upper end, of a latch-piece adapted to be caught under the shoulders of the socket-plate and a link for uniting the latch-piece with the shank.

3. The combination with a socket-plate having an overhanging forwardly-projecting shoulder, and a hinge-plate adapted to be secured in a plane perpendicular to the plane of the socket-plate and having an elastic shank normally curved outwardly from its plane of attachment, of a latch-piece adapted to enter the socket-plate and being constructed to engage the shoulder thereof, and a link pivotally attached to the outer end of the hinge-plate and to the latch-piece intermediate of its ends, the pivots of the link being both within the plane of the shoulders of the socket-plate when the parts are in engagement, substantially as described and for the purpose specified.

605,646. HAT-PIN. HELENA C. MCCARREN, Jersey City, N. J. Filed Oct. 7, 1897. Serial No. 654,220. (No model.)

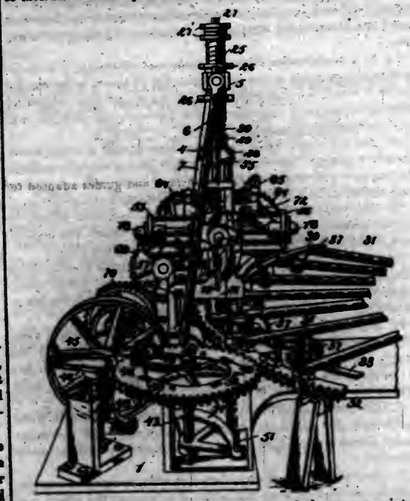
Claim.—1. In a hat-pin, the combination with a frame, of a transverse rod supported thereby, a sleeve revolubly mounted on said rod, a pin attached to said sleeve, having an oblong head in which a slot or opening is formed, and a headed lug or projection attached to said frame and adapted to cooperate with the opening in said head, substantially as described.

2. In a hat-pin, the combination with a frame, of a transverse rod supported thereby, a sleeve revolubly mounted on said rod, a pin attached to said sleeve, having an oblong head in which a slot or opening is formed, and a headed lug or projection attached to said frame and adapted to cooperate with the opening in said head, said pin being provided adjacent to its oblong head with an ogee curve, substantially as described.

605,647. CUTTER FOR TRIMMING HEEL-SEATS AND BANDS FOR BOOTS OR SHOES. OMAR LE GRAND HOBLE, Winthrop, Mass., assignor to Frank Wood, trustee, Boston, Mass. Filed Jan. 26, 1897. Serial No. 620,570. (No model.)

Claim.—A cutting-tool of the character described, comprising a support, a flat non-perforated guard, a flat cutting-disk abutting against the guard and having cutting edges for the rand, there being a clearance or recess between the guard and the disk, and a cutter having cutting edges for the heel-seat and having a concave inner face.

605,648. MACHINE FOR MANUFACTURING GLASSWARE. FRANK O'NEILL, Cicero, Ind. Original application filed Oct. 5, 1897, Serial No. 654,169. Divided and this application filed Mar. 23, 1898. Serial No. 674,223. (No model.)



Claim.—1. In a machine for the manufacture of glassware, alined plungers adapted to be moved, successively, in and out of operative position, means for so moving the plungers, and depressing mechanism operatively engaging an inactive plunger for actuating the alined active plunger.

2. In a machine for the manufacture of glassware, pressing mechanism including a revoluble shaft, pressing-plungers arranged radially thereon with each plunger alining with another plunger through the shaft and adapted, successively, to move to operative position, and mechanism for longitudinally pressing one plunger for actuating the alined active plunger.

3. In a machine for the manufacture of glassware, a movable series of plungers, the plungers being arranged in pairs, cam members movable with the plunger series, and actuating mechanism adapted to engage one plunger of a pair for actuating the other plunger, the actuating mechanism also imparting movement to the cam members for bringing the plungers, successively, to operative position.

4. In a machine for the manufacture of glassware, pressing mechanism including a revolubie series of reciprocating plungers, and plunger-reciprocating mechanism operatively connected to the plunger series for rotating the same.

5. In a machine for the manufacture of glassware, pressing mechanism including a revolubie shaft, pressing-plungers thereon adapted, successively, to move to operative position, and plunger-reciprocating mechanism operatively connected to the shaft for imparting thereto intermittent rotary movement.

6. In a machine for the manufacture of gla ssware, an intermittently-revolubie vertically-reciprocating shaft, pressing-plungers arranged radially on the shaft, each plunger alining with another plunger through the shaft the plungers becoming successively active, and reciprocating mechanism adapted to engage the plunger alining with the active plunger.

7. In a machine for the manufacture of glassware, pressing mechanism including a shaft, pressing-plungers thereon, spiders on the shaft, and plunger-reciprocating mechanism operatively connected with the spiders for intermittently rotating the shaft.

8. In a machine for the manufacture of glassware, pressing mechanism including rotatable pressing-plungers, spiders rotatable therewith, and plunger-reciprocating mechanism operatively connecting with the spiders for intermittently rotating the plungers.

9. In a machine for the manufacture of glassware, pressing mechanism including rotatable plungers, spiders rotatable therewith having curved arms, plunger-reciprocating pitmen, and bolts on the pitmen operatively engaging the curved spider-arms for intermittently rotating the plungers.

10. In a machine for the manufacture of glassware, pressing mechanism including rotatable plungers, spiders rotatable therewith having curved arms, plunger-reciprocating pitmen, spring-actuated bolts on the pitmen operatively engaging the spider-arms for intermittently rotating the plungers, and means for automatically engaging and disengaging the bolts from the spiders.

11. In a machine for the manufacture of glassware, pressing mechanism including rotatable plungers, and two spiders rotatable therewith, two plunger-reciprocating pitmen, one adjacent each spider and operatively connected thereto to alternately partially rotate the spiders and plungers.

12. In a machine for the manufacture of glassware, pressing mechanism including rotatable vertically-reciprocating plungers, plunger-depressing mechanism, and reciprocating means for the plungers and the depressing mechanism adapted to impart longer upward movement to the latter than to the plungers so as to free the plungers for rotation

13. In a machine for the manufacture of glassware, pressing mechanism including rotatable plungers, vertically-reciprocating supports therefor, and eccentrics beneath the supports for reciprocating them and the plungers.

14. In a machine for the manufacture of glassware, pressing mechanism including rotatable plungers, reciprocating supports in which the same rotate, a plunger-depressor and actuating mechanism therefor, rotatable eccentrics for reciprocating the supports, and plunger-rotating mechanism.

15. In a machine for the manufacture of glassware, pressing mechanism including rotatable plungers, vertically reciprocating supports in which the plungers rotate, a depressor adapted to engage an inactive plunger for actuating another plunger, actuating-wheels, pitmen connecting the wheels and the depressor, and eccentrics rotatable with the wheels for reciprocating the supports.

16. In a machine for the manufacture of glassware, pressing mech-

anism including a series of radially-arranged rotatable plungers, a head carrying a plunger-depressor, reciprocating mechanism for the plungers, head-reciprocating mechanism adapted to raise the depressor clear of the plungers for the purpose described, and plunger-turning means.

17. In a machine for the manufacture of glassware, a series of rotatable plungers and means for rotating the plungers, reciprocating supports in which the plungers rotate, a plunger-depressor, actuating mechanism operatively connected to the depressor and plungers, and support-reciprocating eccentrics.

18. The combination of a carrier, molds mounted to swing therein, members adapted to swing the molds and having straight surfaces extending at right angles to the mold-axes, and guides adapted to engage said straight surfaces for holding the molds against swinging.

19. The combination of a carrier, molds mounted therein to swing vertically, and mechanism for righting the molds and holding them upright as they are presented to the pressing-machine.

20. The combination of a carrier, molds rotatable therein, disks rotatable with the molds and flattened on one edge, and guides which the flats of the disks are adapted to engage for holding the molds in fixed position.

21. The combination of a carrier, molds revoluble therein, disks revoluble with the molds and flattened on a line parallel with the mold-top, and guides out of the plane of the mold-axes but in line with the disks, the flats of the latter engaging the guides and holding the molds fixed.

22. The combination of a carrier, molds revoluble therein, disks turnable with the molds and flattened on one edge, and vertically-yieldable guides in line with the disks and adapted to hold the molds as described.

23. The combination of a mold-carrier, wheel 42 geared thereto, a vertically-movable locking-bolt adapted to engage the wheel, and actuating mechanism common to the wheel and bolt.

24. The combination of a mold carrier geared to wheel 42, a wheel-locking bolt, and mechanism actuating simultaneously the wheel and bolt.

25. The combination of a mold-carrier geared to intermittently-rotating wheel 42, a locking-bolt for the wheel, and vibrating cam 54 for actuating the bolt.

26. The combination of a mold-carrier geared to wheel 42, a shaft, an arm adapted to vibrate the shaft, a dog on the arm engaging and intermittently rotating the wheel, cam-spider 54 secured to the vibratory shaft, and a locking-bolt for the wheel actuated by the cam-spider.

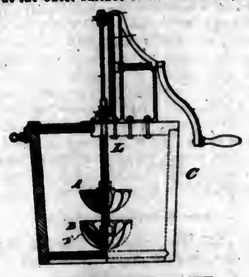
27. The combination of a mold-carrier, a wheel geared thereto formed with beveled depressions in one face, a vibratory arm, means for vibrating the arm, and a spring-actuated bolt carried by the arm and adapted automatically to successively engage the wheel depressions.

28. Molten-glass-feeding mechanism, consisting of oppositely-revoluble wheels, a feeding-box between the wheels, pins revoluble with and projecting beyond the wheel-peripheries, and means for retracting the pins so as to pass the feeding-box.

29. Molten-glass feeding mechanism, including knives, and cam-wheels operatively connected to the knives for actuating the same.

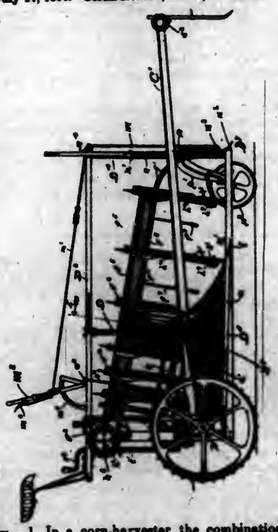
30. Molten-glass-feeding mechanism, including knives having projecting pins, and wheels formed with cam-grooves into which the pins project for actuating the knives when the wheels are set in motion.

31. Molten-glass-feeding mechanism, including feeding-wheels, intermeshing gears on the wheel-journals, shaft 68 operatively connected to the gears, knives beneath the wheels, and actuating mechanism for the knives operatively connected to the said shaft.



32. Molten-glass-feeding mechanism, including intermittently-rotating wheels, cut-off knives beneath the wheels, and actuating mechanism common to the wheels and knives.

33. In a machine for the manufacture of glassware, pressing mechanism, molten-glass-feeding mechanism, a mold-carrier, molds on the carrier, and means for intermittently moving the carrier so as to pass the molds, successively, from the feeding mechanism to the pressing mechanism.



34. In a machine for the manufacture of glassware, pressing mechanism, molten-glass-feeding mechanism, a mold-carrier, molds on the carrier, and actuating mechanism common to the pressing mechanism, the feeding mechanism and the carrier, and adapted to intermittently move the carrier to pass the molds from the feeding mechanism to the pressing mechanism.

605,649. CHURN. JOHN W. OTTO, Altoona, Pa. Filed Sept. 25, 1897. Serial No. 653,084. (No model.)

Claim.—In a churn, the combination with the operating-shafts and bowl-shaped dasher A, which has a series of spirally-arranged scalloped recesses about its outer wall, the dasher B, which is concaved and provided with a series of spirally-arranged scalloped recesses F in its interior wall, with ridges between said scallops, and the blades B' about the outer surface of said dasher B, as shown and described.

605,650. CORN-HARVESTER. DARIUS T. PHILLIPS, Chicago, Ill. Filed July 17, 1896. Serial No. 599,552. (No model.)

Claim.—1. In a corn-harvester, the combination with the axle and its supporting-wheels, of an adjustable frame carrying the operating parts of the machine supported at its rear end portion upon the axle, to be raised and lowered upon its support, a driver's seat on the adjustable frame, a downward-extending bar at the front end portion of the adjustable frame, a wheel provided with a frame sliding upon said bar, a spring confined between the said wheel-frame and bar and tending to raise the front end of the supporting-frame upon the wheel-frame, pulley-and-cable mechanism on the said bar and wheel-frame, and a lever on the adjustable frame, adjacent to the said seat, with which the said mechanism is operatively connected, substantially as and for the purpose set forth.

2. In a corn-harvester, the combination with the frame carrying the operating parts of the machine, of a hollow rotary axle upon which said frame is mounted, and provided with supporting-wheels, and a flexible cable, or the like, extending loosely through and beyond opposite ends of said axle and provided at its ends with horse-attaching means, substantially as and for the purpose set forth.

3. In a corn-harvester, the combination with the frame carrying the operating parts of the machine, of a hollow rotary axle upon which said frame is mounted at its rear end portion and provided with traction-wheels, shafts pivotally connected with the axle on opposite sides of said frame, a flexible cable, or the like, extending loosely through and beyond opposite ends of said axle, a supporting-wheel for the front end portion of the frame, and draft attachments for horses on the free ends of said cable and front end portions of said shafts, substantially as described.

4. In a corn-harvester, the combination with the axle and its supporting-wheels, of a frame in which the operating parts of the machine are mounted, provided with a rear supporting-frame portion having legs adjustably mounted in guides upon the axle, and a divider-frame, comprising a substantially continuous bar secured at opposite ends to said legs and presenting inclined guide-surfaces k', substantially as described.

5. In a corn-harvester, the combination with the axle and its supporting-wheels, of a frame carrying the operating parts of the machine provided with a supporting-frame portion having legs adjustably mounted upon said axle, a divider-frame portion comprising a substantially continuous bar connected at opposite ends with said legs and extending forward to present guide-surfaces k', a forward-extending bar or strip connected at its rear end portion with said supporting-frame portion, and a wheeling support for the forward end portion of said strip, substantially as described.

6. In a corn-harvester, the combination with the axle and its supporting-wheels, of a frame carrying the operating parts of the machine provided with a supporting-frame portion having legs adjustably mounted upon said axle, a divider-frame portion comprising a substantially continuous bar connected at opposite ends with said legs and extending forward to present guide-surfaces k', a forward-extending bar or strip connected at its rear end portion with said supporting-frame portion, parallel brace rods or bars f' f', and a wheeling support for the forward end portion of said strip, substantially as described.

7. In a corn-harvester, the combination with the axle and its supporting-wheels, of a frame carrying the operating parts of the machine provided with a supporting-frame portion having legs adjustably mounted upon said axle, a divider-frame portion comprising a substantially continuous bar connected at opposite ends with said legs and extending forward to present guide-surfaces k', a forward-extending bar or strip connected at its rear end portion with said supporting-frame portion, parallel forward-extending guide-bars D^6 connected at their rear ends to the said supporting-frame portion, guides D^6 extending from the said strip laterally downward and forward to the guides D^4, and a wheeling support for the forward end portion of said strip, substantially as described.

8. In a corn-harvester, the combination with the axle and its supporting-wheels, of a frame carrying the operating parts of the machine provided with a supporting-frame portion having legs adjustably mounted upon said axle, a divider-frame portion comprising a substantially continuous bar connected at opposite ends with said legs and extending forward to present guide-surfaces k', a forward-extending bar or strip connected at its rear end portion with said supporting-frame portion, parallel elevator-shafts journaled at their rear end portions upon the said supporting-frame portion, and at their forward ends supported from the said divider-frame portion, sprocket-wheels upon the elevator-shafts, brackets upon the divider-frame portion, sprocket-wheels upon the said brackets, elevator-chains traveling upon the sprocket-wheels, and a wheeling support for the forward end portion of said strip and divider-frame portion, substantially as described.

9. In a corn-harvester, the combination with the axle, supporting-wheels, shafts C C', and the frame carrying the operating parts of the machine mounted toward its rear end portion on the axle, of a bar or strip D^5 forming the upper portion of said frame, and pick-up bars a' fastened to said strip and extending from opposite sides thereof upward, laterally and downward, and guides a^2 on the shafts C C' through which said pick-ups extend, substantially as and for the purpose set forth.

10. In a corn-harvester, the combination with the frame carrying the operating parts of the machine, outside stalk-guides D^2, divider D^3, cutters and elevators, of guide-boards G G' pivotally mounted toward their forward end portions upon the guides D^2 to swing at their rear end portions over the cutters, springs pressing the said guide-boards normally in the direction of the inside divider, guide-cords, or the like, c^3, attached to the said guide-boards and extending thence upward at opposite sides of the elevators, and a spring connection between the said cords, at the top of the frame, substantially as and for the purpose set forth.

11. In a corn-harvester, the combination with the cornstalk cutting and elevating mechanisms, of a binder for the cornstalks, and a guard for the binder-needle, comprising plates mounted to slide one upon the other in the movement of the needle, and forming an always-closed wall behind the needle, substantially as and for the purpose set forth.

12. In a corn-harvester, the combination with the cornstalk cutting and elevating mechanisms, of a binder for the cornstalks, and a guard for the binder-needle, comprising a pivotal plate e provided with stops in the path of the needle, and a plate e', across which the plate e slides the plates forming an always-closed wall behind the needle, substantially as described.

13. In a corn-harvester, the combination with the cornstalk cutting and elevating mechanisms, of a binder for the cornstalks, a hopper in which the bundle is formed, comprising spring-rods which support the cornstalks and separate to release the bundle, and mechanism for discharging the bundle from the hopper, comprising an eccentric upon one of the binder-shafts, an eccentric-ring in which the eccentric rotates, a bundle engaging and discharging finger b^3 on the ring, and a pivotal swinging support b^2 for the ring at the side thereof opposite the discharging-finger, substantially as and for the purpose set forth.

605,651. HARROW. WILLIS R. PHILLIPS, Saguache, Colo. Filed Apr. 3, 1899. Serial No. 686,014. (No model.)

Claim.—1. In a harrow, the combination with a frame, of a plurality of rotating harrow-teeth journaled in the frame so that the paths of teeth in successive order transverse to the harrow-frame overlap, the several teeth being inclined inwardly toward the median line of the frame, each tooth having a plurality of prongs spreading from its axis, each of the prongs being straight.

2. In a harrow, the combination with a frame, of a plurality of rotatable teeth having their axes laterally oblique as to the frame, each tooth having a plurality of pointed prongs spreading from its axis, each of the prongs being straight.

605,652. ENDOSCOPIC INSTRUMENT. THOMAS S. PITT, Boston, Mass. Filed June 1, 1897. Serial No. 638,591. (No model.)

Claim.—1. A light holder or receptacle for use on an endoscopic instrument, having a curved body portion to receive an incandescent, and a freely-removable concavo-convex guard having inwardly-turned edges fitting on said body portion and having one or more upwardly-turned lugs which operate as reflectors to throw the light upward and forward.

2. A light holder or receptacle for use on an endoscopic instrument, having a curved body portion to receive an incandescent, and a concavo-convex guard fitting on said body portion and having a series of light-emitting apertures and a reflector in the rear of each aperture to throw the light upward and forward.

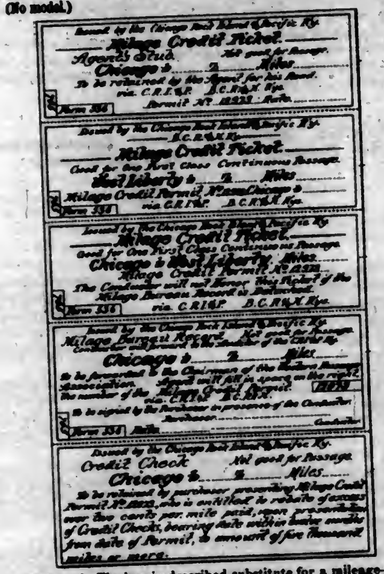
3. A light holder or receptacle for use on an endoscopic instrument, having a curved body portion to receive an incandescent, and a concavo-convex guard fitting on said body portion and having one or more reflectors bent up therefrom, and having one or more light-emitting apertures.

4. A detachable light holder or receptacle for use on an endoscopic instrument comprising a concavo-convex body portion for receiving the incandescent, and having an extended shank with bayonet-slots for attaching it in place, and a removable sliding cover formed with upwardly-turned reflectors.

605,653. DECKER FOR WOOL-WASHING MACHINES. FREDERICK G. SARGENT, Graniteville, Mass. Filed Mar. 26, 1898. Serial No. 675,057. (No model.)

Claim.—The decker-box 23 having the outlet 27 and inclined bottom 24, with oppositely-inclined bottom piece 25.

605,654. CEMENT ROOFING-TILE. GUSTAV SCHULZE, Hoisten, Germany. Filed Jan. 9, 1896. Serial No. 574,836. (No model.) Patented in Germany Oct. 24, 1894, No. 83,980; in Hungary Nov. 11, 1894, No. 1,576; in Belgium Nov. 15, 1894, No. 108,463; in Switzerland Nov. 30, 1894, Nos. 9,490 and 9,800; in Austria Dec. 1, 1894, No. 44/6,196; in Italy Dec. 31, 1894, No. 37,694, and in France Feb. 8, 1895, No. 242,534.



Claim.—1. A tile made in the form of a square plate having its side corners cut away, two upper lap edges having an inner channel

and a raised head, and two lower lap edges, each having a head to fit the said channels of the upper lap edges, a retaining-nose extending downwardly from the under side and lower corner of the tile and recesses adjoining the upper ends of the said corners to receive said retaining-nose, substantially as described.

2. A tile made in the form of a square plate having its side corners cut away and mortar-grooves formed in the edge thereof; two upper lap edges having an inner channel, a raised bead and an outer mortar-groove, and two lower lap edges, each having a bead to fit the said channels of the upper lap edges, a retaining-nose extending downwardly from the under side and lower corner of the tile and recesses adjoining the upper ends of the side corners to receive said retaining-nose, substantially as described.

605,655. RAILWAY-TICKET. JOHN SEBASTIAN and BENJAMIN B. ANDERSON, Chicago, Ill. Filed Mar. 18, 1897. Serial No. 628,300. (No model.)

Claim.—1. The herein-described substitute for a mileage-ticket, comprising a mileage-credit permit and a mileage-credit ticket mutually identified by corresponding characters, substantially as and for the purpose set forth.

2. A substitute for mileage-tickets, comprising a mileage-credit permit, and a ticket provided with a passenger's mileage-credit check and a company's mileage record check, said ticket and checks being provided with a number or the like identifying them with said permit, substantially as and for the purpose set forth.

3. The combination with a railway-ticket, of a passenger's mileage-credit check and a company's mileage-credit record-check, said checks being mutually identified by corresponding characters and one of said checks, at least, being provided with markings from which to determine the amount of credit or rebate and with a purchaser's signature-blank whereon is required the purchaser's signature for prevention of fraudulent manipulation, substantially as and for the purpose set forth.

4. An interchangeable mileage-credit ticket, comprising passage-coupons over the several roads, a passenger's mileage-credit check, and a mileage-bureau credit-record check, said checks being mutually identified by corresponding characters and one of said checks at least provided with markings from which to determine the amount of credit or rebate and with a purchaser's signature-blank, substantially as and for the purpose set forth.

5. The combination with a railway-ticket, of a mileage-credit permit, and a passenger's mileage-credit check, substantially as and for the purpose set forth.

6. The combination with a railway-ticket, of a mileage-credit permit and a mileage-bureau record-check, substantially as and for the purpose set forth.

7. The combination with a railway-ticket, of a mileage-credit permit, a mileage-bureau record-check, and a passenger's mileage-credit check, substantially as and for the purpose set forth.

605,656. CLEVIS. GEORGE H. TAYLOR, near Rockdale, Tex., assignor of two-thirds to R. C. Wallis and D. R. Wallis, Rockdale, Tex. Filed Dec. 2, 1896. Serial No. 614,337. (No model.)

Claim.—1. The combination with a clevis having upper and lower arms, a circular aperture in the end portion of said lower arm, a longitudinal slot in the end portion of said upper arm, extending a little distance to the rear of said aperture, an overhanging lip upon the upper arm of said clevis, said lip extending rearwardly from the front end of the clevis and over said slot whereby it covers one end portion of the slot, said lip being also situated above the upper face of the upper arm to leave a space between said arm and lower face of said lip, of a headed pin having its lower end fitting within the aperture in the lower arm of the clevis, the head of said pin having flat upper and lower faces and adapted to pass into the space between the upper face of the arm and the lower face of the lip, substantially as described.

2. The combination with a clevis having registering apertures at its upper and lower ends, an overhanging lip at the upper end of said clevis, and an under backwardly-extending lip at the lower end of said clevis, of a headed pin to pass through said aperture and to be held in place by said upper lip, while the lower end of said pin is situated to approximately meet the inner face of the under lip.

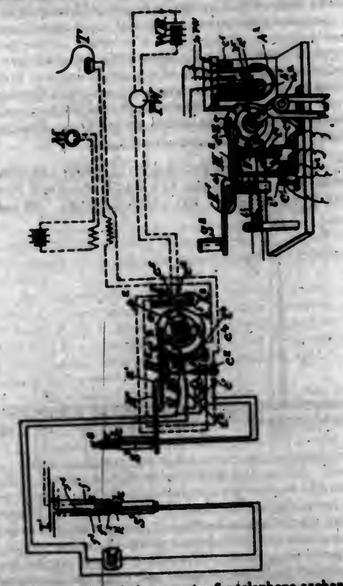
3. The combination of a clevis having upper and lower arms, the lower arm being provided with an opening and the upper arm having a slot registering with the opening and extending inward beyond the same, the L-shaped flange mounted upon the upper arm of the clevis at the outer end of the slot and forming a lip 2 extending inward over the outer portion of the slot, and a pin arranged in the slot and the opening and provided at its upper end with a head extending beneath the lip and cut away at one side, the cut-away portion and the inward extension of the slot cooperating to permit the head to be disengaged from the lip, substantially as described.

605,657. PENCIL. BENJAMIN H. TOOMEY, Westport, Conn. Filed June 19, 1897. Serial No. 641,473. (No model.)

Claim.—1. A pencil having a sheath open at the back end for the insertion of a push-rod, a core in the sheath and a movable pawl within the bore of the sheath and in the rear of the core, as and for the purpose described.

2. A pencil having a sheath of wood or other such material open at the back end for the insertion of a push-rod, a core movable lengthwise in the sheath, and a movable pawl within the bore of the sheath and in the rear of the core, as and for the purpose described.

3. A pencil having a sheath of wood or other such material open at the back end for the insertion of a push-rod, a core movable lengthwise in the sheath, a movable pawl within the bore of the sheath and in the rear of the core, and a friction means for the core near the point of the sheath, substantially as described.



605,658. WITHDRAWN.

605,659. AUTOMATIC APPARATUS FOR TELEPHONE-SWITCH-BOARDS. JULIUS H. WEST, Berlin, Germany. Filed July 8, 1896. Serial No. 598,448. (No model.)

Claim.—1. The combination of telephone-lines, spring-jacks to which the lines are connected, switch-plugs, connecting-wires therefor, a switch operated in one direction by a spring and in the opposite direction by the weight of one of said plugs, an operator's telephone normally connected between said plugs by said switch and disconnected when the switch is operated on the lifting of the plug, an automatic switch adapted to connect a signal-generator between the plugs, and a detent for said automatic switch directly controlled by the weight of the plug which controls said first-mentioned switch.

2. In a telephone system the combination with the subscriber's lines and their respective jacks and plugs, of an automatic switch or contact-making apparatus comprising a continuously-rotating shaft, a disk or disks held frictionally thereon and having a cam-surface and stops, and means for holding said disk from rotation comprising the levers H' H^2, contacts carried by said levers, and contacts actuated by said cam-surface.

3. The combination of plugs S' S^2, connecting-wires therefor, an automatic switch between said plugs comprising a driving-shaft with a cam-disk frictionally mounted thereon, a pivoted stop-lever H^3 normally held in position to stop the cam-disk by the weight of one of the plugs acting thereon, contacts H^2 H^4 normally in connection with plugs S' S^2 and also with the operator's telephone, contacts H^3 H^4 being connected to lever H^3 so as to move therewith, thereby breaking connection with the operator's telephone, and switch-contacts controlled by the cam-disks for connecting and disconnecting a signal-generator to and from the plugs, as described.

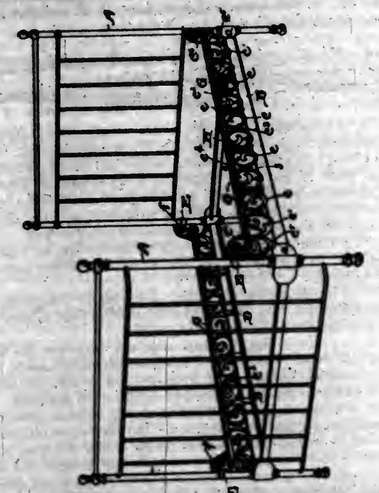
4. An automatic switch apparatus for telephone-exchanges consisting of the combination with the plug or connection-cords, the operator's telephone and the call-battery, of a number of contacts inserted in the said connecting-cords, a shaft continuously rotated by a suitable motor, disks loosely mounted on said shaft and having suitable cam-surfaces, means for coupling said disks with said shaft automatically by the action of lifting up the connection-plug, and means for operating said contacts by the rotation of the said disks, substantially as and for the purpose set forth.

605,660. METALLIC BED. WILLIAM W. BALDWIN, Cleveland, Ohio, assignor to the Cleveland Co-Operative Stove and Hollow Ware Foundry Company, same place. Filed June 4, 1897. Serial No. 639,410. (No model.)

Claim.—1. A side rail for a bed, adapted to be removably secured to the bed, and consisting of a longitudinal bar having secured to it separate contacting sections of metal, substantially as described.

2. A bed-rail composed of separate contacting sections of metal free at their lower ends and bound together by a longitudinal bar, substantially as described.

3. A bed-rail composed of separate sections of metal secured at or near their upper ends to a longitudinal bar and having their lower ends free, said sections engaging with each other near their lower ends, substantially as described.

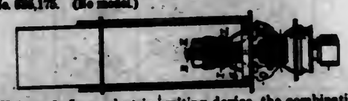


4. A bed-rail composed of a plurality of sections having lugs on one of their ends by which they are adapted to engage with their next neighbor, and a longitudinal bar to which they are all secured, substantially as described.

5. A bed-rail composed of a plurality of sections secured near their upper ends to a longitudinal bar, and some of said sections having near their upper ends the lug c^3 which extends over the next section and near the lower ends the lug c^3 which extends behind that section, substantially as described.

6. A bed-rail composed of a plurality of sections secured to a longitudinal bar and having on its rear side clips adapted to engage with the side bar of a metal bed, and having near its ends clips adapted to engage with the bed-posts, substantially as described.

7. The combination with a bed having posts A and a side bar B, of a separable rail engaging with and supported by the bar B, and secured to the posts A, substantially as described.



8. The combination with a bed having posts A and a side bar B, of a separable rail embracing the said side bar between the lower edge of the rail, and clips D carried on the inner side of the rail and embracing the said posts between the ends of the rail and clips E carried on the inner side of the rail, substantially as described.

9. The combination with a bed having posts A, plates a and a side bar B, of a separable rail C supported by the bar B and having its lower edge extending upwardly at its ends to clear the plates a, said rail having its upper edge extending upwardly at the ends and being secured to the posts at said upwardly-extending ends, substantially as described.

10. A section for a bed-rail, consisting of a body C having integrally the leg c^3, the leg c^2 and the beveled portion c^4 arranged substantially as shown.

605,661. INSULATING ELECTRODES FOR ELECTRIC GAS-LIGHTING BURNERS. ADRIAN L. BOSART, Jamaica, N. Y., assignor to William R. M. Jordan, New York, N. Y. Filed May 5, 1897. Serial No. 635,175. (No model.)

Claim.—1. In an electric igniting device, the combination with one of the electrodes formed of a metal wire or strip, of an insulating-shield through which said wire or strip is threaded, substantially as set forth.

2. In an electric igniting device, the combination with one of the electrodes formed of a metal wire or strip, of a mica shield through which said wire or strip is threaded, substantially as set forth.

3. The combination with an electrically-ignited gas-burner, of a flexible insulating shield or screen between the burner and one of the electrodes, substantially as set forth.

4. The combination with an electrically-ignited gas-burner, of a flexible insulating sheet-like shield or screen to which one of the electrodes is secured, substantially as set forth.

5. The combination with an electrically-ignited gas-burner, of an insulating screen or shield between the burner and the other electrode, substantially as set forth.

6. The combination with an electrically-ignited gas-burner, of a mica screen or shield between the burner and the other electrode, said electrode being carried by the shield, substantially as set forth.

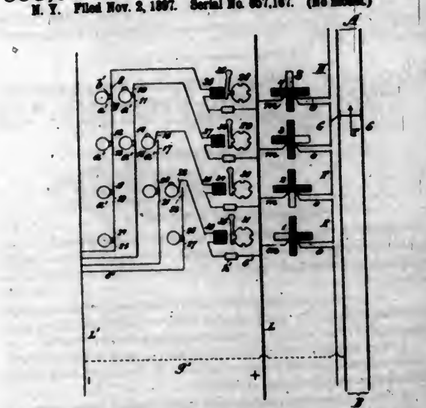
7. The combination in an electric gas-lighting device, of a conducting-electrode, an insulating flexible shield supporting the said electrode and insulating it from adjacent metallic parts by having the same threaded therethrough, as described, and means for securing said strip in place, substantially as set forth.

605,662. LOCK-RAIL FROG. JOHN W. CLOSE, Buffalo, N. Y., assignor of one-half to George L. Lovejoy, same place. Filed Mar. 16, 1898. Serial No. 673,682. (No model.)

Claim.—1. In a railway-frog, a metal bed bearing on the bases or flanges of the wing-rails, 2, and of the diverging rails, 14 15, having the form described and shown, provided with recesses, 3, for securing the wing-rails, 2, with the lugs, 4, and receptacle, 11, for securing the point, 12, also the receptacle, 13, for securing the diverging point-rail, 14, with keyway, 19, and recess, 21, all constructed and arranged substantially as shown and described.

2. In a railway-frog, the bed or base resting on and supported by the lower flanges of the wing-rails, 2, and diverging rails, 14 15, and having a receptacle adapted to receive and closely conforming to the point, 12, and a point-rail resting in said receptacle, in combination with a combined wedge and foot-guard fitting into a recess between and securing the diverging rails, 14 15, in place, all constructed and arranged substantially as shown and described.

3. In a railway-frog, a wedge, 16 having the lug, 25, with the recesses, 20 26, keyway, 19, and pins, 29, all substantially as shown and described.



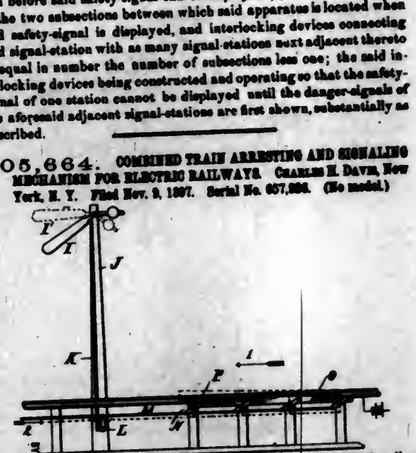
4. In a railway-frog, the wedge, 16, having the foot-guard, 24, integral with said wedge and in line with one of its sides, all as shown and described.

5. In a railway-frog, the combination of a wedge with the frog-point, said wedge extending past the point, thereby protecting the joint formed with the obtuse end of the point, and the diverging point-rail to which the point is conjoined, all as shown and described.

6. A railway-frog provided with an opening or recess formed by diverging arms of said frog, adapted to receive and secure the diverging rails, 14 15, and resting on the flanges of said diverging rails; together with the wedge, 16, and foot-guard, 24, integral with said wedge, which rest on and are supported by the flanges of said diverging rails, all constructed, arranged and secured to operate as shown and described.

7. The combination of pins, 17, in recess, 13, of the base-plate with the wedge, 16, as shown and described.

605,668. ELECTRIC RAILWAY. CHARLES H. DAVIS, New York, N. Y. Filed Nov. 2, 1897. Serial No. 657,167. (No model.)



Claim.—1. In an electrical railway a line divided into insulated divisions, signal devices respectively located between the successive divisions, means for actuating said signal devices successively to give a definite indication, and means controlled by each signal device for then establishing electrical circuit in the line-divisions between which it is located, substantially as described.

2. In an electrical railway, a line divided into insulated divisions, signal devices respectively located between successive divisions, each device being constructed to exhibit a danger-signal and a safety-signal, and means controlled by each signal device for establishing current in the two line-divisions between which said device is located, when the safety-signal of that device is exhibited, substantially as described.

3. In an electrical railway a line divided into insulated divisions, a signal device associated with each division and constructed to exhibit a danger-signal and a safety-signal, and means controlled by said signal device for interrupting electrical circuit through the associated line-division when the danger-signal of that device is exhibited, substantially as described.

4. In an electrical railway, a line divided into insulated sections, each section having two or more insulated subsections, signal-stations located at the boundaries of said sections and subsections, a signal apparatus located at each substation and constructed (1) to exhibit a danger-signal and a safety-signal (2) to show said danger-signal successively as many times less one as there are substations in each section before said safety-signal can be displayed (3) to establish current in the two subsections between which said apparatus is located when said safety-signal is displayed, and interlocking devices connecting said signal-station with as many signal-stations next adjacent thereto as equal in number the number of subsections less one; the said interlocking devices being constructed and operating so that the safety-signal of one station cannot be displayed until the danger-signals of the aforesaid adjacent signal-stations are first shown, substantially as described.

605,664. COMBINED TRAIN ARRESTING AND SIGNALING MECHANISM FOR ELECTRIC RAILWAYS. CHARLES H. DAVIS, New York, N. Y. Filed Nov. 2, 1897. Serial No. 657,204. (No model.)

Claim.—1. The combination in an electric railway with a line conductor and an electric-motor vehicle receiving current therefrom through a traveling contact bearing on said conductor, of means for controlling the closing and breaking of electrical circuit between said contact and said conductor from a station on the line, thereby permitting continued progress of said vehicle over, or causing its arrest at, the point of circuit establishment and breakage, substantially as described.

2. The combination in an electric railway with a line conductor and signal in proximity thereto and an electric-motor vehicle receiving current from said conductor through a traveling contact bearing on said conductor, of means for actuating said signal and also simultaneously controlling the closing and breaking of electrical circuit between said contact and said conductor at a point distant from said signal, substantially as described.

3. The combination in an electric railway with a line conductor and a movable guard device, of a signal located at a distance from said guard device, and means for actuating said signal and said guard device simultaneously; whereby when said signal is set in danger position said guard device is also placed in position to separate and so break electrical circuit between said line conductor and a body moving upon and along the surface of said conductor and meeting the said device, substantially as described.

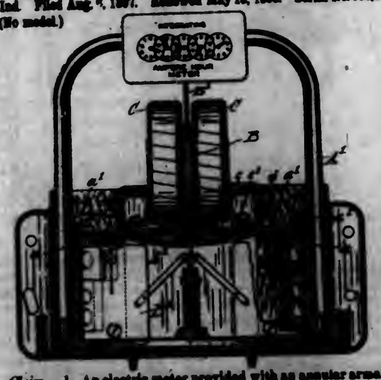
4. The combination in an electric railway of a line conductor and an electric-motor vehicle, a contact-arm on said vehicle normally closing circuit between said vehicle-motor and said line conductor, and a brake mechanism on said vehicle controlled by said arm; the aforesaid parts being constructed and arranged so that when circuit is open between said contact-arm and said conductor said brake mechanism shall be controlled thereby to arrest the motion of said vehicle, substantially as described.

5. The combination in an electric railway of a line conductor and electric-motor vehicle, a movable arm on said vehicle normally closing circuit between said vehicle-motor and said line conductor, a stop movably secured in proximity to said conductor, a signal in proximity to said conductor and means for simultaneously actuating said signal in predetermined manner and also for adjusting said stop in position to cause said arm on meeting it to move out of contact with said conductor, substantially as described.

6. The combination in an electric railway of a line conductor and electric-motor vehicle, an arm on said vehicle normally closing circuit between said vehicle-motor and said line conductor, a movable cam in proximity to said conductor having its upper surface normally below the upper surface of said conductor, and means for actuating said cam to carry its upper surface above the upper surface of said conductor, and thereby causing said arm in moving over said cam to break electrical connection with said conductor, substantially as described.

7. The combination in an electric railway of a line conductor and electric-motor vehicle, an arm on said vehicle normally closing circuit between said motor-vehicle and said line conductor, a signal in proximity to said line conductor, a movable cam in proximity to said conductor having its upper surface normally below the upper surface of said conductor, and mechanism for simultaneously actuating said signal in a predetermined manner and also for actuating said cam to carry its upper surface above the upper surface of said conductor and thereby causing said arm in moving over said cam to break the electrical connection with said conductor, substantially as described.

8. The combination of a line conductor, an electromotor-vehicle, a movable arm on said vehicle normally making electrical contact with said line conductor, a movable body in proximity to said conductor having its upper surface normally below the upper surface of said conductor, means for displacing said movable body so that it shall move said arm out of contact with said conductor, and a brake mechanism on said vehicle; the said brake mechanism being controlled by said arm when moved as aforesaid, to arrest the motion of said vehicle, substantially as described.



9. The combination in an electric railway wherein current is taken from a charged conductor by a traveling contact thereon, of the conductor B, bar O having inclined surface F, pivoted levers N supporting said bar, and rod M for actuating said levers, substantially as described.

10. The combination in an electric railway wherein current is taken from a charged conductor by a traveling contact thereon, of the conductor B, bar O, pivoted levers N supporting said bar, rod M actuating said levers, pivoted signal-arm I, rod K for moving said arm, and mechanism for transmitting the motion of rod K to rod M, substantially as described.

11. The combination in an electric railway of a car, having a brake mechanism, a conductor's valve R controlling the same, a contact-arm F actuating said valve with conductor B along which said contact-arm F travels, bar O supported in proximity to said conductor, and means for raising said bar to move said contact-arm out of contact with said conductor, substantially as described.

12. The combination in an electric railway of a car, having a brake mechanism, a conductor's valve R controlling the same, a contact-arm F actuating said valve with conductor B along which said contact-arm F travels, bar O supported in proximity to said conductor means for raising said bar to move said contact-arm out of contact with said conductor and a visual signal constructed to be exhibited in definite position by said means, substantially as described.

605,665. ELECTRIC METER. THOMAS DUNCAN, Fort Wayne, Ind. Filed Aug. 9, 1897. Renewed May 18, 1898. Serial No. 681,090. (No model.)

Claim.—1. An electric motor provided with an annular armature and a plurality of magnetic fields part of which are set up within and part without the armature, one field being on an axis extending between two other fields that are set up on separate axes on the opposite side of the annular wall of the armature from the first field, circuit connections energizing part of the fields with currents of differing phase, and means for inductively energizing the other part.

2. An electric motor provided with an annular armature and a plurality of coils part of which are located within and part without the armature, one coil being arranged on an axis extending between two other coils that are arranged on separate axes on the other side of the annular wall of the armature from the first coil, circuit connections for energizing two of the coils by currents of differing phase, and means for inductively energizing the third coil.

3. An electric motor provided with an annular armature, a magnetic field set up exterior to the armature, upon an axis extending between two fields set up within the armature upon separate axes, circuit connections for energizing the outer and one inner field by currents of differing phase, and means for inductively energizing the third field by a current of still different phase.

4. An electric motor provided with an annular armature, coils exterior to the armature, coils within the armature, circuit connections for energizing said outer and inner coils, a magnetic core having part of its poles inclosed by said inner coils, and closed circuits on the other poles of said core.

5. An electric motor provided with an annular armature, coils exterior to the armature, coils within the armature, circuit connections for energizing said outer and inner coils by currents of differing phase, closed circuits within the armature apart from the first inner coil, and means for inductively energizing said closed circuits.

6. An electric motor provided with an annular armature, coils exterior to the armature connected in circuit, a cross-shaped magnetic core within the armature, coils on two poles of the core, also connected in circuit and closed circuits on the other poles of the core.

7. An electric motor provided with an annular armature, coils exterior to the armature, arranged upon an axis intersecting the latter and connected in circuit, a cross-shaped magnetic core arranged with its axes at an angle to the axis of the outer coils, coils on two poles of the core, also connected in circuit, and closed circuits on the other poles of the core.

8. An electric motor provided with an annular armature, coils exterior to the armature arranged upon an axis intersecting the latter and connected in circuit, a cross-shaped magnetic core within the armature arranged with its axes at an angle to the axis of the outer coils, coils on two poles of the core also connected in circuit, closed circuits on the other poles of the core, and means for adjusting the angular arrangement of the core with respect to the axis of the outer coils.

9. An electric motor provided with an annular armature, a series field exterior to the armature, a magnetic core within the armature made of cross shape with its axes intersecting each other and the axis of the series field at the center of the armature, coils on two opposite poles of the core connected in circuit, and closed circuits on the other two poles of the core.

605,666. THILL-COUPLING. JOHN EDGAR, Rochester, Minn. Filed Oct. 26, 1897. Serial No. 656,268. (No model.)

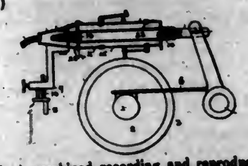
Claim.—1. The combination, of the shackle, provided with slots or notches to receive the thill-iron, with vertically-movable clamping-jaws, having arms extending across the slots or notches in the shackle, and means for drawing down said movable member or jaw, substantially as described.

2. The combination, of the shackle, provided with the vertical slots or notches, with the jaw provided with horizontal slots or notches, a screw upon said movable jaw, and a swiveled nut upon said shackle, as and for the purpose specified.

3. The combination, of the relatively movable shackle and clamp, having opposed slots or openings to receive a thill-iron, with a swiveled member on one of said parts, engaging a threaded part on the other for the adjustment thereof, substantially as described.

4. The combination, of the shackle, and the movable jaw, provided with vertically and rearwardly opening slots, with means for locking said movable jaw, substantially as described.

5. The combination, with a shackle having slots 6 and a swiveled nut 5, of a clamp 9 having slots 10 and screw 11 to engage said nut 5, and said slots 6 and 10 being substantially at right angles to each other and adapted to receive the studs or trunnions upon a thill-iron, substantially as described.



6. The combination, of a shackle, with a clamp, a screw for adjusting said clamp, said shackle and clamp having openings to receive a thill-iron, and having opposed portions to engage and hold said iron, and said clamp being adapted to support said thill-iron and raise the same out of engagement with said shackle, substantially as described.

7. The combination, of a shackle and clamp, having oppositely-extending thill-iron slots, and having opposed portions to engage and hold a thill-iron, means for adjusting said clamp, and said clamp being adapted to support said thill-iron and move it into engagement

with said shackle and raise it out of engagement therewith, substantially as described.

8. The combination, of a shackle having slots to receive a thill-iron, and a movable bar or clamp, provided with slots extending oppositely with respect to those in the shackle, means for adjusting said movable clamp and said clamp being adapted to carry a thill-iron into engagement with said shackle and move the same out of engagement therewith, substantially as described.

605,667. PHONOGRAPH. THOMAS A. EDISON, Llewellyn Park, N. J. Filed Dec. 3, 1890. Renewed Feb. 4, 1897. Serial No. 622,621. (No model.)

Claim.—1. A combined recording and reproducing device for phonographs, comprising a reversible diaphragm-holder, a recording-point on one side and a reproducing-point on the other side, whereby by reversing the holder either the recording or reproducing point may be brought into operative position, substantially as set forth.

2. The combination, in a phonograph having a suitable phonogram-blank, of a hollow structure, and recording and reproducing devices in different sides thereof, said structure being arranged to move on its axis to bring the recorder or the reproducer into operative position, substantially as described.

3. The combination with a support for a phonograph recorder and reproducer, consisting of a tube, of said recorder and reproducer mounted in different sides of the tube, substantially as described.

4. The combination of a support for a phonograph recorder and reproducer, consisting of a tube mounted to rotate in different sides of which said recorder and reproducer are mounted, and an inner tube, substantially as described.

5. The combination of a support for a phonograph recorder and reproducer, consisting of a tube mounted to rotate, in different sides of which said recorder and reproducer are mounted, said tube being connected to the phonograph-feeding devices, substantially as described.

6. A recorder and reproducer carrying arm, a portion of which is tubular in combination with the recorder and reproducer, substantially as described.

7. A recorder and reproducer carrying arm having end sections and a journaled tube interposed between said sections in combination with a recorder or reproducer supported by the tube, substantially as described.

8. The combination of a support for a phonograph recorder and reproducer, consisting of a tube mounted to rotate, and a speaking or hearing tube communicating with one end of said tube, substantially as described.

9. The combination of a support for a phonograph recorder and reproducer, consisting of a tube mounted to rotate, an inner tube, and a speaking or hearing tube communicating with the space between the two tubes, substantially as described.

10. The combination with a guide-rod, a sleeve thereon to which the recorder-supporting arm is connected, and a guide-bar on which the arm bears, of said supporting-arm, and a recorder and reproducer mounted on different sides thereof but movable into and out of operative position, substantially as described.

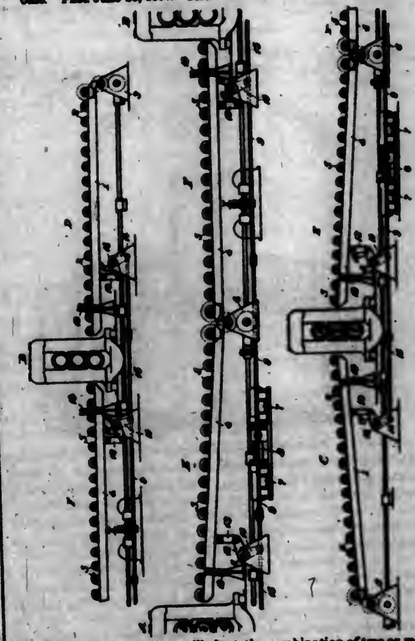
11. The combination with a support mounted to rotate repeatedly in the same direction, of a phonograph-recorder on one side thereof and a reproducer on another side, substantially as described.

12. The combination, with a support movable repeatedly in the same direction, of a recorder thereon at one side, and a reproducer thereon on a different side, and means for holding the support in the position to which it is turned, substantially as described.

13. In a talking-machine, the combination with the carriage and the tablet-carrying cylinder, of a pivoted holder adapted to carry a recording and transcribing diaphragm and so formed that said diaphragms will be held in a different plane with respect to each other, and means for bringing either of said diaphragms into contact with the tablet, as and for the purpose set forth.

605,668. MIXER. THOMAS A. EDISON, Llewellyn Park, N. J. Filed June 20, 1897. Serial No. 642,513. (No model.)

Claim.—1. In a mixer, the combination of a trough, a shaft mounted longitudinally within the trough, a plurality of longitudinal bars supported by said shaft parallel therewith and mixing devices carried by said bars and working within the trough, substantially as set forth.



2. In a mixer, the combination of a trough, a shaft mounted within said trough, a plurality of longitudinal bars supported by the shaft parallel therewith and a plurality of mixing devices removably secured to said bars and adjustable longitudinally thereon, substantially as set forth.

3. In a mixer, the combination with the trough and the shaft, of longitudinal bars supported by the shaft parallel therewith, and plows and spreaders carried by the bars, substantially as set forth.

4. In a mixer the combination of a trough, a shaft mounted longitudinally therein, longitudinal bars supported by the shaft parallel therewith and plows and spreaders removably secured to said longitudinal bars and alternately arranged thereon, substantially as and for the purpose set forth.

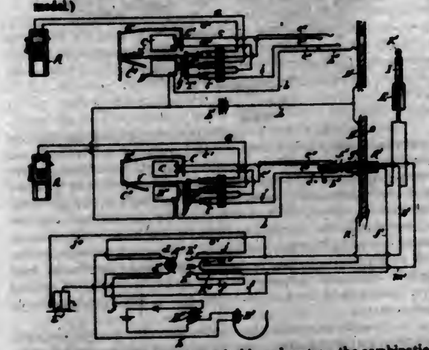
5. In a mixer, the combination with the trough, of the shaft, spiders on the shaft carrying longitudinal bars, plows and spreaders supported by these bars, and truss-rods lengthwise of the shaft to stiffen the shaft, substantially as set forth.

605,669. ROLLING-MILL. EDWARD V. HYNES, Youngstown, Ohio. Filed June 30, 1897. Serial No. 643,571. (No model.)

Claim.—1. In a rolling-mill plant, the combination of two or more stands of rolls arranged in, or approximately in, a common line of

feed, two or more feed-tables forming a continuous line of feed arranged between adjacent stands of rolls and means for shifting the ends of the feed-tables adjacent to the rolls in the same or in opposite directions, substantially as set forth.

2. In a rolling-mill plant, the combination of two or more stands of rolls arranged in, or approximately in, a common line of feed, feed-tables having reversible feed-rollers and forming a continuous line of feed arranged between adjacent stands of rolls, and mechanism for shifting the ends of the table adjacent to the rolls in the same or in opposite directions, substantially as set forth.



3. In a rolling-mill plant, the combination of two or more stands of rolls arranged in a common line of feed, two or more feed-tables forming a continuous line of feed arranged between adjacent stands of rolls, means for shifting the ends of said tables adjacent to the rolls in the same or in opposite directions, feed-tables arranged at the ends of the line or train of rolls, and means for shifting the roll ends of the tables in the same or in opposite directions, substantially as set forth.

4. In a rolling-mill plant, the combination of two or more stands of rolls arranged in or approximately in a common line of feed, a feed-table having reversible feed-rollers arranged between adjacent stands of rolls and forming a continuous line of feed, and mechanism for shifting the ends of the table adjacent to the rolls in the same or opposite directions, substantially as set forth.

5. In a rolling-mill plant, the combination of two or more stands of rolls arranged in a common line of feed, two or more feed-tables arranged between adjacent stands of rolls, feed-tables arranged at the ends of the line or train of rolls and mechanism for shifting the ends of the intermediate table or tables independently of each other, but simultaneously with the inner ends of the end tables, substantially as set forth.

6. In a rolling-mill plant, the combination of two or more stands of rolls arranged in a common line of feed, two or more pivotally-mounted feed-tables arranged between adjacent stands of rolls, and mechanism for independently shifting the free ends of those feed-tables, substantially as set forth.

605,670. TELEPHONE-SWITCHBOARD SYSTEM. FRED G. HOLMS, Detroit, Mich. Filed July 3, 1897. Serial No. 643,886. (No model.)

Claim.—1. In a telephone-switchboard system, the combination of a line-circuit including an annunciator-actuating coil, a circuit-breaker, and a spring-jack, a second circuit including opposed contact-terminals and a restoring-coil having an armature adapted to actuate the circuit-breaker of the line-circuit, means actuated by said restoring-coil for restoring the annunciator-shutter to its normal position, and a plug having a contact-surface which normally passes into and out of contact with the terminals of said second circuit and alternately closes and opens the circuit of the restoring-coil when inserted in the spring-jack of the line-circuit and actuates the circuit-breaker therein to open said line-circuit.

2. In a telephone-switchboard system, the combination of a telephone-circuit including a spring-jack and an annunciator-actuating coil, a second circuit including a spring-contact terminal and an annunciator-restoring coil adapted to actuate the annunciator-restoring mechanism, a switchboard apertured to receive a plug and having upon the face thereof around said aperture a conductor forming part of the circuit of the restoring-coil and standing opposed to the spring-contact terminal of said second circuit, a plug adapted to enter said aperture to engage said spring-jack having a contact-surface thereon which passes but momentarily into contact with the spring-terminal of the circuit of the restoring-coil and with said opposed conductor around said aperture, thereby alternately closing and opening the circuit of the restoring-coil when said plug is inserted in or withdrawn from said spring-jack.

3. The combination of a telephone-line including a spring-jack and an annunciator-coil adapted to actuate the annunciator-shutter, a restoring-coil included with a source of electricity and a contact-terminal in a normally open circuit, a ringing-key, a plug having a contact-surface adapted to engage said terminal and carrying a line connected with said contact-surface which is adapted to form a portion of the circuit of said restoring-coil and which is connected with the ringing key, to enable the circuit of said restoring-coil to be closed by said ringing-key to restore the annunciator-shutter through the cord of said plug.

4. In a telephone system, the combination of a telephone-line including an annunciator-actuating coil and a circuit-breaker, an electromagnet included with a source of electricity in a normally open circuit, means operated by said electromagnet for actuating said circuit-breaker when said magnet is energized, a ringing-key adapted to close the circuit of said electromagnet when said key is in a ringing position, whereby the line-circuit of the calling subscriber is opened when the operator rings the subscriber called.

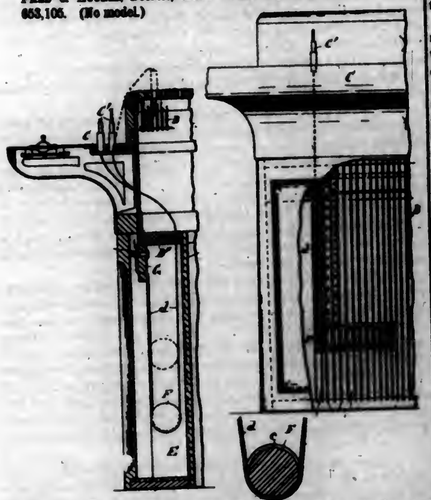
5. The combination of an annunciator consisting of a centrally-pivoted angle-plate or shutter whose opposed faces stand in separate planes and one of which faces carries an indicating character, means for moving said shutter on its pivot, a movable opaque screen having an opening which registers with said shutter, an indicating character on a transparent panel in line with said opening, a source of light behind said screen, and means for moving said drop or shutter to permit the light to shine through said opening and reveal said character on said panel and means for moving said screen to reveal the character on said shutter.

6. In an annunciator, the combination of a transparent plate having an indicating character on a portion of the surface thereof, a source of light, a movable drop or shutter consisting of an angle-plate one face of which is interposed between said light and character, the other face of said shutter carrying an indicating character corresponding with the character on said plate, means for actuating said shutter to move one face thereof from between said light and the character on said transparent plate and expose the character on the other face of said shutter through said transparent plate, and means for restoring said shutter to its normal position.

7. In an annunciator, the combination of an indicating character upon a transparent plate, a source of light behind said character, a movable drop or shutter consisting of a pivoted angle-plate one face of which is normally held in a vertical position interposed between said light and character, and the other face of which is of greater specific gravity and stands in a substantially horizontal position, means for releasing said shutter to cause the horizontal face thereof to swing downward and carry the vertical face to a horizontal position to permit the rays of light to shine upon and reveal said character, and means for restoring said shutter to exclude the light from said character, substantially as set forth.

8. In an annunciator, the combination of the annunciator magnet or coil, the pivoted shutter or drop consisting of an angle-plate having an indicating character upon its lower face, the armature of the annunciator-coil adapted to engage and retain said shutter in a normal position, in which the upper face of said shutter stands vertically, a strip of glass in front of said shutter the upper portion of which is frosted, an indicating character upon the frosted glass, a movable opaque screen in front of said glass having an opening therethrough which registers with said character on the glass and with the upper face of said shutter when in its normal position and with the lower face of said shutter when said screen is moved downward, a source of light behind said shutter, means for energizing the annunciator-coil to drop said shutter rendering visible the character on the lower face of said shutter through the strip of clear glass when the opening in said screen is placed in front of the lower face of said shutter, substantially as set forth.

9. In an annunciator, the combination of an indicating character visible by illumination, a normally open electric circuit containing a source of light, which source of light stands adjacent to said character, a movable shutter interposed between said light and character, means for moving said shutter to reveal said character, means connected with said shutter for closing the light-circuit upon the moving of said shutter from before said character, and means for restoring said shutter and simultaneously opening said circuit.



10. In an annunciator, the combination of the movable shutter consisting of an angle-plate whose opposed faces stand substantially at right angles to each other, said plate being pivoted near the point of angle and supported so that one of its faces normally stands in a vertical position and the other of its faces in a horizontal position, means for causing said shutter to swing on its pivot so as to present its normally vertical face in a horizontal position and its normally horizontal face in a vertical position, a hook projecting from the inner angle of said plate, a restoring coil or magnet having an arma-

ture provided with an arm which engages the hook of said plate or shutter when its normally vertical face is in a horizontal position, and means for energizing said magnet to actuate said arm and restore said shutter, substantially as set forth.

11. The combination in a series of spring-jacks, of a continuous supporting-rod common to all of the springs of said jacks, said rod being supported at its opposite ends and covered throughout its length with a continuous casing of insulating material, a series of springs mounted upon said insulating-covering, intermediate the supports at the ends of said rod, means for preventing the springs from turning upon said rod, a series of insulating-collars upon said covering dividing said springs, and means for binding said parts together.

12. The combination in a spring-jack, of a supporting-rod common to all of the springs of said jack, an insulating-covering upon said rod flattened upon one face, a series of springs mounted upon said insulating-covering having an aperture therein provided with a straight face which coincides with the flat portion of said insulating-covering, a series of insulating-collars mounted upon the insulating-covering of said rod and interposed between said springs, and the nuts on the ends of said rod for binding said parts together.

605,671. CORD-WEIGHT FOR TELEPHONE-SWITCHBOARDS. FRED G. HUGHES, Detroit, Mich. Filed Sept. 27, 1897. Serial No. 653,105. (No model.)

Claim.—1. In a cord-weight for telephone-switchboards, the combination of a narrow confining-way composed of smooth parallel plates, a thin heavy disk located in said way whose opposed faces are smooth and stand contiguous to the wall of said way, and the cord passing around the arc of said disk in said way and supporting said disk.

2. In a cord weight for telephone-switchboards, the combination with a suitable supporting frame, a series of dividing-partitions arranged parallel within said frame forming a series of vertical ways between their adjacent faces, a series of disks located in said ways and having peripheral grooves, the opposed faces of said disks being free from elevations and standing contiguous to the vertical walls of said ways, the looped cords depending within said ways passing around the arcs of said disks and supporting said disks within the depending loops thereof.

605,672. BICYCLE-SADDLE. JONATHAN A. HUNT, Westborough, Mass. Filed Aug. 21, 1897. Serial No. 649,089. (No model.)

Claim.—1. In a saddle for bicycles, the combination with the castle-plate, and the pommel-plate, or plate at the front end of the saddle, having an adjusting-screw mounted and turning therein, and the spring-rods extending between the castle-plate and pommel-plate, and secured thereto, of a nose-piece having a hole therein to receive the front end of said adjusting-screw on which it is supported, and a central portion or bar in line with the adjusting-screw, and the two upwardly-extending side portions, each having an opening or perforation therethrough for the passage of the strips of lacing, and the upper ends of said side portions being in a plane above the central bar, and strips of lacing secured to the castle-plate, and passing through the openings in the nose-piece to extend upon the under side of the central bar thereof, and a cover extending over the lacing, and depressed longitudinally through its central portion, substantially as shown and described.

2. In a spring-support for a bicycle-saddle, the combination with a spring made out of one piece of wire, forming two pairs of integral rods, the lower pair connected and forming a loop at their forward ends, and bent or curved outwardly at their rear ends to form horizontal spiral springs, and the rear ends of the upper pair of rods bent to form eyes for the attaching-screws, and the forward ends disconnected and free, to be attached to the front or pommel of the saddle, of a supplemental spring, bent at its middle portion to form a loop, to be connected with or locked into the loop at the forward ends of the lower pair of rods of the first-mentioned spring, and having two vertical spiral coils formed therein, intermediate the loop portion and the ends, substantially as shown and described.

3. A clamp for bicycle-saddle springs, &c., comprising an external split body or shell 16, having recesses in its inner edges to receive the rods of the spring, and two perforated ears 16' to receive the clamping-bolt, and an internal shell or clamp-jaw 18 within the shell 16, made in one part, and split or divided at one point only, and provided with recesses to receive the rods of the spring, and also recessed projection 18' to receive the clamping-bolt; and the contiguous surfaces of the ears 16', and of the clamp-jaw 18, being tapered or beveled, substantially as shown and described.

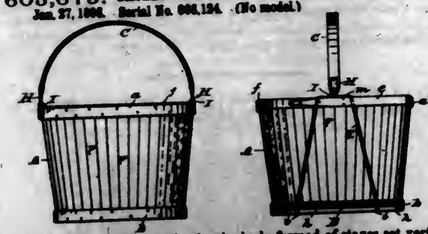
605,673. BICYCLE-SADDLE. JONATHAN A. HUNT, Westborough, Mass. Filed Aug. 21, 1897. Serial No. 649,090. (No model.)

Claim.—1. In a saddle for bicycles, the combination with the castle-plate, the pommel-plate, a spring intermediate the castle and pommel, and a nose-piece supported on the end of an adjusting-screw turning in the pommel-plate, of a wire loop connected at its front end to the nose-piece, and provided at its rear end with vertically-extending eyes, the tops of which extend above the plane of said loop, and a transverse holder attached to said eyes, and strands of leather or lacing extending from the castle-plate and looped around said holder, and a top or cover having two elevated or raised portions, the front ends of which rest upon and are held up by the top of the vertical eyes in the loop at the front end of the saddle, substantially as shown and described.

2. In a bicycle-saddle, the combination with the pommel-plate, and the metal castle-plate of curved or partial tubular shape in cross-section, of a spring made out of one piece of wire, and forming two pairs of integral rods, one pair below the other, and the forward free ends of the upper pair secured to the pommel-plate, and vertical attaching-eyes formed at the rear ends to extend within the castle-plate, and be secured thereto, and horizontal spiral coils intermediate the two pairs of rods at their rear ends, and a loop at the front ends of the lower pair of rods, substantially as shown and described.

3. In a bicycle saddle, the combination with the pommel-plate, and the metal castle-plate of curved or partial tubular shape in cross-section, of a spring made out of one piece of wire, and forming two pairs of integral rods, one pair below the other, and the forward free ends of the upper pair secured to the pommel-plate, and vertical attaching-eyes formed at the rear ends to extend within the castle-plate, and be secured thereto, and horizontal spiral coils intermediate the two pairs of rods at their rear ends, and a loop at the front ends of the lower pair of rods, said loop connected with the upper pair of rods by a supplemental spring, and said supplemental spring, substantially as shown and described.

4. In a clamp for bicycle-saddle springs, &c., the combination with the external solid or unsplit shell or casing of substantially triangular shape, and having a threaded boss or extension on one side thereof, and a bolt or clamping device for said boss, of a clamp-shell

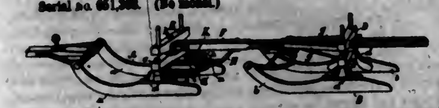


or device extending within the external shell, and having an opening therethrough to receive the horizontal support of the saddle-post, and centrally split or divided through its upper portion only above said opening, and having recesses in its outer edges to receive the rods of the spring, said recesses and the split or divided portion of the clamp-shell, and the clamping-bolt being in the same horizontal plane, substantially as shown and described.

605,674. COMBINED PENCIL-CASE AND COMB-CASE. NATHAN D. INGRAM, Holyoke, Mass. Filed Dec. 30, 1897. Serial No. 664,716. (No model.)

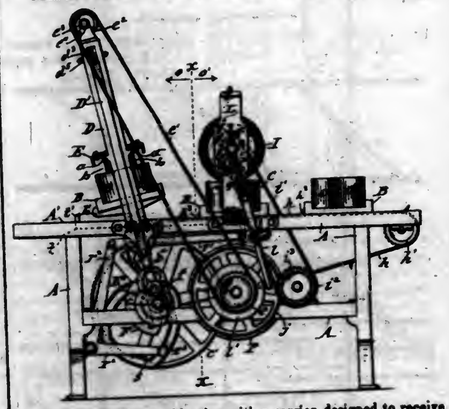
Claim.—As a new article of manufacture a combined pencil-case and comb-case comprising a pencil-holding tube adapted to receive at one end a pencil, and provided with a longitudinal slot extending part way the length of the tube from the opposite end thereof, and a reversible comb having a longitudinally-grooved back which fits in, and engages the edges of, the slot in the pencil-holding tube, and can slide back and forth therein, and provided with an end tube or plug adapted to fit the end of the pencil-tube to which the comb is applied, substantially as hereinbefore set forth.

605,675. BASKET. TALBOT B. JOHNSON, Vandersburg, Ind. Filed Jan. 27, 1898. Serial No. 668,134. (No model.)



Claim.—1. A basket having its body formed of staves set vertically and an inset bottom secured thereto, said staves being each composed of a parallel strip having thin and flexible edges and each stave overlapping at one edge the adjacent edge of the adjoining stave and being overlapped at its opposite edge by the adjacent edge of the adjoining stave, hoops binding and securing said staves together, draft-rods engaging the bottom of said basket and drawing against the top hoops thereof, and a suitable bail or handles attached to said draft-rods, substantially as shown and described.

2. A basket composed of staves set vertically and each stave comprising a strip having parallel edges and rendered thin and flexible by being dressed down at the outside, said edges overlapping adjacent edges so that each stave has one edge overlapped and one edge overlapping adjacent edge, a solid bottom secured inside somewhat above the bottom of the staves, hoops binding said staves together and the bottom thereto, and draft-rods drawing against the top of said basket and against the bottom and set angularly so that they diverge from the top downward and engage the bottom at points approximately equidistant, substantially as shown and described.



3. In a basket, the combination of the body formed of the staves F having the straight inner side J and the curved outer side K and edges N P, one edge overlapping the other, the bottom B having grooves at the periphery, the draft-rods E drawing against said bottom and against the top of said body, the loop I in said rods above said body, the binding-hoops, and the bail C provided with the binder G and having the plates H engaging the loop in said draft-rods, substantially as shown and described.

605,676. SLEIGH. TABOR G. MANDT, Stoughton, Wis., assignor to the T. G. Mandt Vehicle Company, same place. Filed Sept. 11, 1897. Serial No. 651,202. (No model.)

Claim.—In an oscillating sleigh, the runners and knees secured thereto, the beams secured to the knees, and the bolster pivoted upon the beam, combined with the reach, the angular plate pivoted at its front end to the under side of the front beam and having its rear end rigidly secured to the reach; the semicircular plate G secured at its front end to the knees, the hanger K which passes through the reach and the plate H, and the lock upon the plate; the front ends of the semicircular plate being thickened, substantially as shown and described.

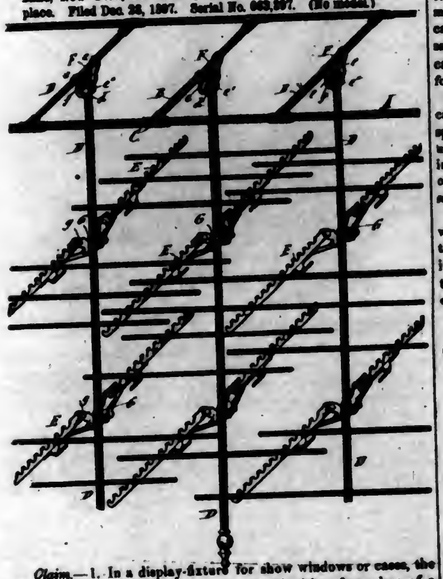
605,677. CAN-CLEANER. FRANK A. ODIN, Bridgeton, N. J. Filed Nov. 17, 1897. Serial No. 658,796. (No model.)

Claim.—1. The combination with a carrier designed to receive the can open at the top and filled with the substance to be canned, of a plunger sustained in an inclined position over said carrier, and mechanisms adapted to lift the can in an inclined position to the plunger, as set forth.

2. The combination with the carrier designed to receive the can open at the top and filled with the substance to be canned, of a plunger sustained in an inclined position over said carrier, means imparting lateral movement to the plunger, and mechanisms adapted to lift the can in an inclined position to the plunger, as set forth.

3. The combination of the main supporting-frame formed with horizontal ways, a tray riding on said ways and carrying the filled cans, mechanisms adapted to lift the tray from the ways and simultaneously tilt the tray to support the cans in an inclined position, laterally-movable plungers disposed correspondingly inclined over the tray to enter the open tops of the cans, means for placing the plungers normally central over the cans, and mechanisms releasing the cans from the centering means and imparting lateral movement to the plungers, as set forth.

4. The combination of the main frame formed with horizontal ways, a tray riding on said ways and carrying the filled cans, parallel guides rising from said frame and inclined in the direction of the lengths of the ways, a plate supported at its ends in an inclined position on said guides and movable laterally thereon, conical sockets, respectively, on the top and bottom of said plate, reciprocating slides on the aforesaid guides, pins connected to the slides and entering the lower sockets during the upward movement of the slides and thereby setting the plate into its normal position, rotary shafts supported on the slides and entering the upper sockets during the downward movement of the slides and cranked to impart lateral movement to the plate, plungers attached to said plate, and mechanism lifting and tilting the tray to cause the plungers to enter the open tops of the cans, as set forth.



5. In combination with the main frame, horizontal ways and can-trays riding on said ways, standards mounted on the sides of the main frame, journal-boxes adjustably supported on said standards, a rotary cylindrical brush disposed axially at right angles to the aforesaid ways and having its shaft mounted in the said journal-boxes, a lever fulcrumed on the side of the main frame and formed with a longitudinally-sliding extension receiving through it the end of the brush-shaft, collars fixed to said shaft at opposite sides of the lever extension, and a rotary cam imparting oscillatory motion to said lever substantially as set forth and shown.

6. The combination with the main frame formed with parallel horizontal ways, plungers over the ways and inclined in the direction of the ways, a reciprocating feeder depositing the can-trays under the plungers, mechanism lifting and tilting the trays to cause the plungers to enter into the open tops of the cans and resetting the trays upon the ways, a rotary brush beyond the plungers, and conveyers moving the tray from under the plungers to the brush, as set forth.

7. The combination with the main frame formed with parallel horizontal ways, plungers disposed over said ways and inclined in

the direction of the ways, a reciprocating feeder depositing the tray under the plungers, mechanism lifting and tilting the trays to cause the plungers to enter the cans, a rotary cylindrical brush disposed beyond the plungers and axially parallel with the tray, means for imparting longitudinal reciprocating motion to said brush, and conveyers moving the tray from under the plungers to the brush, as set forth.

605,678. DISPLAY-FIXTURE FOR STORES. EMIL T. PALMENBERG, New York, N. Y., assignor to J. R. Palmenberg's Sons, same place. Filed Dec. 28, 1897. Serial No. 663,997. (No model.)

Claim.—1. In a display-fixture for show windows or cases, the combination with the main frame provided with a frame-bar, of a depending bracket-supporting bar, and a clamp for connecting the bracket-supporting bar adjustably to the frame-bar, said clamp consisting of a hook member provided with a head having a screw-opening for receiving the screw-threaded neck of the bracket-supporting bar and a shoe member opposing the hook member and provided with a guide-pin guided through an opening in the said head for the hook member, substantially as set forth.

2. In a display-fixture for show windows or cases, a bracket-supporting bar provided with a screw-threaded end or neck, in combination with a clamp comprising a hook member provided with a head having a screw-threaded opening for receiving said screw-threaded neck, and a shoe member opposing said hook member and provided with a guide-pin guided through a guide-opening in the head of said hook member, substantially as set forth.

605,679. MOUNTING FOR ELECTRIC MOTORS. EMIL B. W. REICHEL and FRIEDRICH W. V STEIN, Berlin, Germany, assignors to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed Jan. 27, 1896. Serial No. 668,153. (No model.)

Claim.—1. In a support for electric motors, the combination with a spring-carriage carried upon a relatively stationary part maintained between the said motors, of a supporting-rod, means for connecting the said motors upon opposite sides of the spring-carriage with the supporting-rod, and a supplemental connection tending to secure the conjoint movement of said motors, substantially as described.

2. The herein-described mounting for motors of electrically-propelled vehicles, consisting of a spring-carriage mounted upon the truck of the said vehicle, a supporting-rod carried by said spring-carriage whereon the motors are mounted upon either side of said spring-carriage, a non-rigid mounting connecting said supporting-rod and motors, and a supplemental or secondary connecting part uniting said motors.

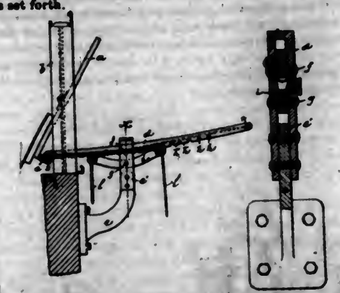
3. In a motor-support for electrically-propelled vehicles, the combination with a spring-carriage having opposing springs *f f'* mounted upon a cross-beam *d'*, of supporting-rods *d* carried by said spring-carriage, motors *c* mounted at either end of the supporting-rods by means of link connections *d'*, and lugs *g* forming secondary connections for said motors, substantially as described.

4. The combination with the truck of an electrically-driven vehicle, of motors *c* connected with the axles of the wheels, spring-carriages *e* consisting of supporting parts *e'* and opposing springs *f f'* mounted upon a cross-beam *e'* of the said truck, supporting-rods *d* carried upon said spring-carriages, link connections *d'* uniting the said motors with the supporting-rods upon either side of the spring-carriages, and slotted lugs *g* united to form a supplemental connection for the said motors, substantially as described.

5. The herein-described motor-supporting truck, having a spring-carriage supported upon a relatively stationary part, two motors respectively disposed upon either side thereof, a supporting-rod mounted upon the spring-carriage, non-rigid connections uniting the supporting-rod and motors approximately in the planes of the motors' centers of gravity, and a supplemental or secondary connecting part uniting said motors.

6. The combination in a truck for electrically-driven vehicles with two propelling-motors, of a supporting rod or rods connected thereto approximately in the vertical planes of their centers of gravity, means for supporting said rod or rods, and supplemental connections uniting the said motors, whereby their motions are substantially equalized, substantially as described.

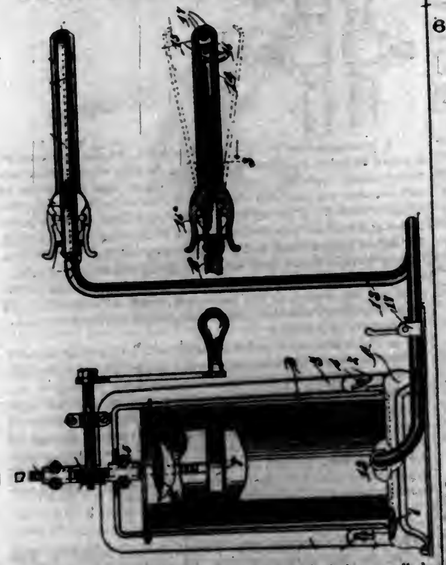
605,680. BED-BOTTOM. JAMES B. RYAN, New York, N. Y. Filed July 1, 1897. Serial No. 643,173. (No model.)



Claim.—1. In a bed-bottom the combination of a frame and an elastic fabric stretched thereon, and two or more endwise-elastic cables disposed beneath the fabric, and having their ends secured to the end rail, a hook at or near the center through which said cables pass and by means of which they are connected to each other; said hooks being lengthwise adjustable and adapted to regulate the distance between the parts of the cables passing through it.

2. In a bed-bottom the combination of a frame and an elastic woven-wire fabric stretched thereon, and a plurality of endwise-elastic cables; two or more being secured to each end rail of the frame and connected centrally in pairs, extending from opposite end rails, and hooks connecting said cables; said hooks being secured together by means of a transverse tie.

605,681. LIFT FOR SASHES, TRANSOMS, OR SKYLIGHTS. GEORGE SEWING, Newark, N. J. Filed Nov. 20, 1897. Serial No. 659,322. (No model.)

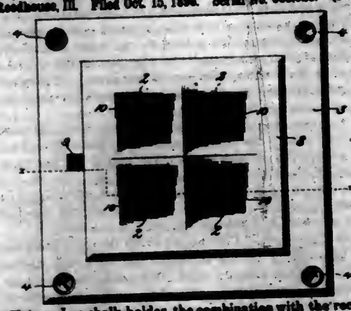


Claim.—1. The combination of the rack *d*, having a series of notches or recesses in its lower edge, a keeper *d'*, for said rack and having a transverse pin to enter said notches, a lever arranged in said keeper and having its opposite ends grooved or forked at the upper edges to engage said rack, and means for operating said lever, substantially as set forth.

2. In a sash-operator, the combination with a rack *d*, pivoted at one end to the sash, and supporting-pin *f*, of a lever upwardly curved and having its opposite ends grooved or forked at the upper edges to engage said rack, and cords attached to the opposite ends of said rack and passed over the sheaves on the ends of said lever, substantially as set forth.

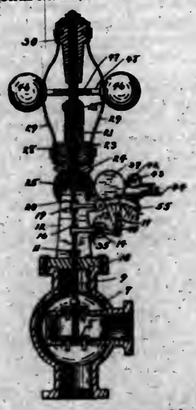
3. In a sash-operator, the combination with a keeper *d'*, arranged on the wall of a rack *d*, sliding longitudinally in said keeper, a transverse pin *f*, to support said rack and a lever *i*, pivoted in said keeper in the same vertical plane with the rack, the ends of said rack having means for fastening the ends of cords thereto, and the ends of the lever having sheaves to receive the cords, and said cords, substantially as set forth.

605,682. VAGINAL SYRINGE. ELISABET SEIBERT, Chicago, Ill. Filed June 17, 1897. Serial No. 641,159. (No model.)



Claim.—1. A vaginal syringe comprising a bed-plate, a cylinder mounted thereon, an annular groove in said bed-plate surrounding said cylinder and adapted to receive alcohol, a plunger in said cylinder connected with a rack-bar, and a crank-shaft carrying a pinion adapted to intermesh with said rack-bar to operate said plunger.

2. A vaginal syringe comprising a bed-plate, a removable standard carried thereby, a cylinder on said bed-plate, an annular groove in said bed-plate surrounding said cylinder and adapted to receive alcohol, a plunger in said cylinder, a rack-bar on said plunger, a crank-shaft on said standard carrying a pinion adapted to intermesh with said rack-bar to operate said plunger, an inlet-port in the upper end of said cylinder below the upper limit of movement of said plunger, and an outlet-port in the lower end of said cylinder.



3. In a vaginal syringe, the combination with a nozzle provided with means for expanding the vagina beyond the delivery end thereof, of a syringe comprising a cylinder, a plunger therein, means for operating said plunger to force said water out of said nozzle, and a groove in the bed-plate of said syringe and surrounding said cylinder adapted to receive alcohol for heating the contents of said cylinder, substantially as described.

605,688. BILLIARD-CHALK HOLDER. GEORGE B. SEVERLING, Reedhouse, Ill. Filed Oct. 15, 1896. Serial No. 608,886. (No model.)

Claim.—In a chalk-holder, the combination with the rectangular base 3 having screw-receiving holes by which it may be secured to a support and provided with the series of four rectangularly-arranged chalk-receiving pockets 1 beyond which said base extends, of the follower-plates 5, and coil-springs 6, located in the pockets and adapted to support the chalk blocks 2, the retaining-plate 8 hinged at one side of the pockets 2, and having flared or bevel openings 10 coincident with and smaller than the same and adapted to overlap the chalk blocks, and a fastening device for retaining the free end of the plate 8 in a closed position against the said springs.

605,684. GOVERNOR. FRED W. SPACKE, Indianapolis, Ind. Filed Oct. 1, 1897. Serial No. 653,794. (No model.)

Claim.—1. In a governor, the combination with a valve and speed-controlled means, of intermediate adjustable connecting mechanism between said valve and said speed-controlled means whereby, when the said parts are in their normal working positions, the throw of the valve may be made greater or less for any given change of speed of said speed-controlled means without changing the relative positions of the speed-controlled means and valve.

2. In a governor, the combination with a valve and a rotating speed-controlled means, of intermediate adjustable connecting mechanism between said valve and speed-controlled means whereby, when the said parts are in their normal working positions, the throw of the valve may be made greater or less for any given change of speed of said speed-controlled means without changing the relative positions of the speed-controlled means and valve.

3. In a governor, the combination with a valve and governor-balls operated by the engine, of intermediate adjustable connecting mechanism between said valve and said governor-balls whereby, when the said parts are in their normal working positions, the throw of the valve may be made greater or less for any given change of speed of the engine without altering the relative positions of the governor-balls and valve.

4. In a governor, the combination with the valve and governor-balls, of a lever connected at one end with said balls, and an adjustable connection between said lever and the valve whereby, when the valve and balls are in their normal working positions, the throw of the valve may be made greater or less for any change of speed of the

governor-balls without altering the relative positions of the governor-balls and valve.

5. In a governor, the combination with the valve and governor-balls, of a lever having one arm in engagement with the stem of said valve, a second lever, a link carried by the other arm of the first lever and adjustably connected with one arm of the second lever whereby the throw of the valve may be increased or diminished, and a connection between the other arm of the second lever and the governor-balls, substantially as described.

6. In a governor, the combination with the valve and governor-balls, a lever having one arm adjustably connected with said valve, a second lever, a link carried by the other arm of the first lever and adjustably connected with one arm of the second lever whereby the throw of the valve may be increased or diminished, a stem adjustably connected to the other end of the second lever, and a connection between said balls and stem, substantially as described.

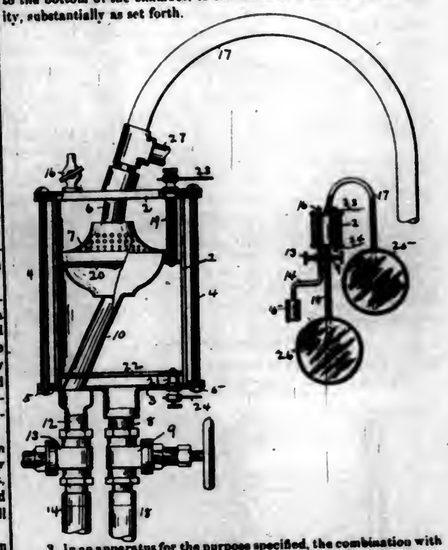
7. In a governor, the combination with the valve and governor-balls, a lever having one end adjustably connected with said valve, a second lever, a link carried by the other arm of the first lever and adjustably connected with one arm of the second lever whereby the throw of the valve may be increased or diminished, a stem adjustably connected to the other end of the second lever, and a spring engaging said first lever in position to open the valve and to hold the stem in engagement with the governor-balls.

8. In a governor, the combination with the valve and governor-balls, a lever having one end adjustably connected with said valve, a second lever, a link carried by the other arm of the first lever and adjustably connected with one arm of the second lever whereby the throw of the valve may be increased or diminished, a stem adjustably connected to the other end of the second lever, a spring engaging said first lever in position to open the valve and to hold the stem in engagement with the governor-balls, and means for adjusting the tension of said spring, substantially as and for the purpose set forth.

9. In a governor, the combination with the valve, of a weight, an arm carried by said weight and adjustable thereon, means carried by said arm for engaging the governor-belt and sustaining said weight, and intermediate connecting mechanism between said weight and valve whereby, upon the breaking of the belt, the said weight will close the valve.

10. In a governor, the combination with the valve, of a weight, an arm carried by said weight and angularly adjustable thereon, means carried by said arm for engaging the governor-belt and sustaining said weight, a shaft, an arm carried by said shaft in engagement with said valve, a second arm carried by said shaft, and a link between said arm and weight whereby, upon the breaking of said belt, the said weight will operate to close the valve, substantially as described.

11. In a governor, the combination with the frame thereof, of a spring 29, eye 47 provided with an arm 48 extending through said spring, nut 49 mounted upon said arm, weight 46 adapted to engage said nut and to clamp the spring between the weight and nut, and a collar 51 secured to the arm, all combined and arranged to cooperate substantially as and for the purpose set forth.

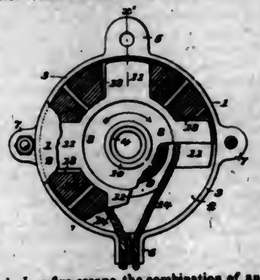


12. In a governor, the combination with the frame thereof, of a spring 29, eye 47 provided with an arm 48 extending through said spring, nut 49 mounted upon said arm, weight 46 adapted to engage said nut and to clamp the spring between the weight and nut, a collar 51 secured to the arm, a notch formed in the periphery of the weight, and an ear carried by the nut and adapted to be bent down into said notch and thereby lock the weight upon the nut, substantially as described.

13. In a governor, the combination with the spring 29, of a net 49 provided with a stem 50 extending through said spring, a weight adapted to engage said stem, a notch formed in the weight, and an ear carried by the nut and adapted to be bent down into said notch and thereby lock the weight upon the stem.

605,685. APPARATUS FOR COOLING AND PURIFYING LIQUIDS. ORRIN W. SWIFT, New Haven, Conn. Filed July 16, 1897. Serial No. 644,702. (Model.)

Claim.—1. In an apparatus for the purpose specified, the combination with a chamber having means whereby air can be exhausted therefrom and having an outlet-pipe leading therefrom, of a hollow head located within said chamber near the top thereof and provided with a series of jet or spray openings, an inlet-pipe leading to said head, a contact device located adjacent to said head and adapted to be engaged by a liquid issuing from the latter, a second contact device located near the bottom of said chamber, and means for connecting said contact devices respectively with the opposite poles of a generator of electricity, said inlet-pipe forming the short leg and said chamber and its outlet-pipe the long leg of a siphon, substantially as set forth.



2. In an apparatus for the purpose specified, the combination with a closed chamber having means whereby air can be exhausted therefrom and admitted thereto, of an outlet-pipe leading from the bottom of said chamber and provided with a valve, a spray-head located within said chamber near the top thereof, an inlet-pipe leading to the interior of said spray-head, said inlet-pipe forming the short leg and said chamber and outlet-pipe forming the long leg of a siphon, and means for subjecting a liquid, in its descent from said spray-head to the bottom of the chamber, to the action of a current of electricity, substantially as set forth.

3. In an apparatus for the purpose specified, the combination with a closed chamber provided with a valve through which the air can be exhausted therefrom, an outlet-pipe leading from the bottom of said chamber and provided with a valve, a hollow head located within said chamber and having in its upper side a series of jet or spray openings, a sediment-pipe leading from the bottom of said head through the wall of said chamber and provided with a valve, a heat inlet-pipe leading to said hollow head and forming the short leg of a siphon, two contact-rings located within said chamber between said hollow head and the bottom of the latter, and means for connecting said rings respectively with the opposite poles of a generator of electricity, substantially as described.

4. The combination with a chamber, as 1, of an atomizer, as 7, located within said chamber near the top thereof, an outlet-pipe leading from the bottom of the chamber, an inlet-pipe leading to said atomizer, the insulated binding-post 19 passing through the upper head of the chamber and carrying at its lower end a contact device, as the ring 20, and the insulated binding-post 21 passing through the lower head of said chamber and carrying at its upper end a contact device, as the ring 22, said inlet-pipe forming the short leg and said chamber and its outlet-pipe forming the long leg of a siphon, substantially as and for the purpose described.

605,686. FIRE-ESCAPE. DAVID L. WESTERN, Chicago, Ill. Filed Feb. 28, 1898. Serial No. 672,092. (No model.)

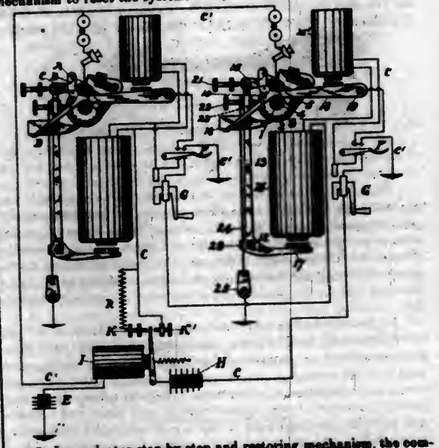
Claim.—1. In a fire-escape, the combination of an inclosing casing provided with an interior cylindrical track-surface, a sheave mounted to rotate within said housing and provided with duplicate series of radial guide projections, and a rope-groove arranged centrally between said series of projections, and duplicate series of friction shoes arranged to slide radially on said projections and adapted to contact with the cylindrical track-surface of the housing, substantially as set forth.

2. In a fire-escape, the combination of an inclosing casing formed in counterpart halves, each provided with a central tubular neck and an interior cylindrical track-surface, a sheave arranged to rotate on said necks and provided with duplicate series of radial projections, and with a rope-groove arranged centrally between said series of projections, and duplicate series of friction-shoes arranged to slide radially on said projections and adapted to contact with the cylindrical track-surface of the housing, substantially as set forth.

3. In a fire-escape, the combination of an inclosing casing formed in counterpart halves, each provided with a central tubular neck, marginal connecting-lugs, tubular guide-lugs, suspension-lug and an interior cylindrical track-surface, a sheave arranged to rotate on said necks and provided with duplicate series of radial projections, and with a rope-groove arranged centrally between said series of projections, and duplicate series of friction-shoes arranged to slide radially on said projections, and adapted to contact with the cylindrical track-surface of the housing, substantially as set forth.

605,687. COTTON SCRAPER AND CULTIVATOR. ESEK W. DEVINEY, Augusta, Ga. Filed Feb. 7, 1898. Serial No. 669,402. (No model.)

Claim.—1. A cotton-scraper consisting of a plow-beam and handles, a standard, a cultivator-point in front of said standard, a head formed of two parts G and G^3, each of said parts of the head provided with a lug projecting from its face, and blades therefor, each blade having a recess in its upper edge to receive the said projecting lug substantially as described.



2. In a cotton-scraper the combination of the two divergent blades, each one provided with a segmental recess in its upper edge and a perforation alongside of said recess, with the head provided with segmental lugs projecting from its face substantially as described.

3. A cotton-scraper blade having its top and bottom edges parallel, and within its upper edge a segmental recess, with a perforation alongside of said recess substantially as described.

605,688. SELECTOR SIGNALING SYSTEM. THOMAS C. DRAKE, Malta, Ohio. Filed Sept. 17, 1897. Serial No. 652,017. (No model.)

Claim.—1. The combination in a selector system, of a line-circuit connecting a series of step-by-step and restoring mechanisms at a series of stations respectively, means for moving the series of step-by-step mechanisms to a predetermined position by an intermittent current, and means for operating the series of restoring mechanisms to reset the series of step-by-step mechanisms to normal on passing a current of greater strength than said intermittent current, the stepping and restoring mechanisms comprising the electromagnets M, and M', connected in said line-circuit whereby said diminished current may operate the ratchet-wheel, lever and pawls to rotate the contact-disk, and the normal current may operate the bifurcated lever to disengage the pawls respectively, the contact-disk and contact-screw to close a signaling-circuit at a predetermined position of rotation of said series of mechanisms, and the segment-gear to return the ratchet-wheel and contact-disk to normal position on operating the restoring mechanism to reset the system.

2. The combination in a selector system of a line-circuit connecting a series of step-by-step and restoring mechanisms at a series of stations respectively, means for moving the series of step-by-step mechanisms to a predetermined position by an intermittent current, and means for operating the series of restoring mechanisms to reset the series of step-by-step mechanisms to normal on passing a current of greater strength than said intermittent current, the stepping and restoring mechanisms comprising the ratchet-wheel, lever and pawls to rotate the contact-disk, the contact-disk and contact-screw to close the signaling-circuit at a predetermined position of rotation of said series of mechanisms, the pawl with protuberance B, acting with the stop-pin A, whereby the said pawl is locked into the teeth of said ratchet-wheel to check the momentum of the said ratchet-wheel and contact-disk, the bifurcated lever operated by said normal current to disengage the pawls, and the segment-gear to return the ratchet-wheel and contact-disk to normal position on operating the restoring mechanism to reset the system.

3. In a selector step-by-step and restoring mechanism, the combination of the ratchet-wheel and contact-disk, the pawls, lever and electromagnet M, to step the ratchet-wheel and contact-disk, the bifurcated lever 18, and electromagnet M' to disengage the pawls, the weighted segment-gear and pinion-gear to return the ratchet and contact-disk to normal position, the contact-disk and contact-screw 22, to close the circuit through the auxiliary signaling devices, and the means to check the momentum of the ratchet and contact-disk which consists of the pawl 15, with the protuberance B, operating in relation with the pin A, carried by the bifurcated lever 18, whereby the said pawl is locked into the teeth of said ratchet, substantially as specified.

4. In a selector system, the combination of a series of mechanisms connected by a line-circuit, a battery and switches located in said line-circuit, a supplemental circuit connected to each of said mechanisms or switches, a current-controlling relay located in said supplemental circuit and adapted to diminish the normal current through said line-circuit when said switches are in position to close said supplemental circuit, and to pass the normal current through said line-circuit when said switches are in position to leave said supplemental circuit open, means at each mechanism to pulsate said diminished current through the series of mechanisms, said mechanisms adapted to be synchronously stepped to a predetermined position by the diminished intermittent current, and synchronously restored to normal position by the said normal current.

5. The combination in a selector system, of a line-circuit connecting a series of step by-step and restoring mechanisms at a series of stations respectively, an operating-battery located in said circuit, a series of contact-cranks, and a series of switches located at said stations by means of which the said line-circuit may be opened and closed and the current pulsated through the step-by-step mechanism, a supplemental circuit connected to each of said mechanisms or switches, a battery-controlling relay with its operating-battery located in said supplemental circuit by means of which the normal current in the line-circuit may be diminished when it is desired to step the mechanisms and restored when it is desired to restore the mechanisms, the step-by-step and restoring mechanisms comprising the ratchet-wheel, lever and pawls to rotate the contact-disk, the contact-disk and contact-screw to close the signaling-circuit at a predetermined position of rotation of said series of mechanisms, the bifurcated lever operated by the said normal current to disengage the pawls, and the segment-gear to return the ratchet-wheel and contact-disk to normal position on operating the restoring mechanism to reset the system.

6. In a selector step-by-step and restoring system the combination of a station apparatus consisting of the ratchet-wheel and contact-disk the pawls and lever operated by the electromagnet M to step the said ratchet and contact-disk, the contact-disk and contact-screw 22 to close the circuit C, the bifurcated lever 18 operated by

the electromagnet M' to disengage the pawls, the pinion-gear and segment-gear to return the ratchet and contact-disk to normal position, the means of checking the momentum of the ratchet-wheel consisting of the pawl 15 with the protuberance B operating with the pin A carried by the lever 18, the contact-crank to pulsate the current through the system, and the switch F to normally close the circuit C.

605,689. BICYCLE-SADDLE. THOMAS J. KIRKPATRICK, Springfield, Ohio. Filed July 15, 1897. Serial No. 644,739. (No model.)

Claim.—1. The combination in a saddle such as described having a flexible seat, of a spring-frame formed of two substantially parallel plates connected by a circular body which lies substantially in the same vertical plane with both of said plates but which projects above and below the points of connection with said plates, and a coil-spring connecting the free ends of said plates, said coil-spring being arranged beneath the pommel end of said seat, substantially as specified.

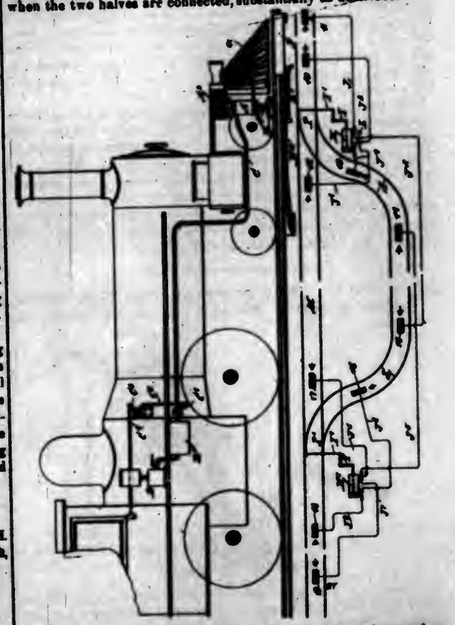
2. The combination with the flexile seat, a spring-frame having two substantially parallel plates each forming the entire saddletree and supporting-base, respectively, said plates being formed integral with a circular spring portion, a cantle for said seat secured to one of said plates adjacent to said circular body, and a hook or clip adjustably connected to the opposite end of said plate, and a flexile seat extending from said hook or clip to said cantle, and a coil-spring connecting the free ends of said plates, said coil-spring being arranged beneath the pommel end of said saddle, substantially as specified.

605,690. SELF-THREADING LOOM-SHUTTLE. MITCHAEL H. LEVEILLE, Worcester, Mass., assignor of one-half to John G. Smith, same place. Filed Nov. 18, 1897. Serial No. 658,942. (No model.)

Claim.—1. A shuttle-threader comprising an outer plate, which is adapted to be attached to the side of a shuttle-body, said plate having a projecting portion embodying a guide-plate and a tubular thread-guide, the outer plate and tubular thread-guide having a thread-receiving slot or kerf.

2. In a shuttle-threader, the combination with a shuttle-body, of an outer plate attached to the side thereof, and having an angular projecting guide-plate with a tubular thread-guide at the base thereof, the outer plate and tubular thread-guide having a kerf or slot on a line with one of the side walls of the guide-plate, and a spring carried by the outer plate so as to lie over the kerf or slot therein, substantially as shown.

3. A shuttle-threader, comprising an outer plate having an eye, a guide-plate and a tubular thread-guide, the guide-plate being provided with a prong which projects from the upper inner end thereof, the outer plate and tubular thread-guide having a kerf or slot, substantially as shown.



4. In combination with a shuttle-body having a recess, of a shuttle-threader rigidly secured in said recess and comprising an outer plate B having an eye, a slot or kerf which extends from said eye through the plate, a plate B' which projects at an angle from the first-mentioned plate the kerf being on a line with one edge thereof, said plate B' having a prong d' and a tubular thread-guide d on a line with the eye in the plate B, said plate above the eye having a recess and an intersecting spring for the kerf secured within the recess, substantially as shown and for the purpose set forth.

605,691. PNEUMATIC SWITCH-THROWING MECHANISM. GEORGE R. BARTHOLOMEW, Ridge, Pa. Filed Oct. 19, 1897. Serial No. 656,729. (No model.)

Claim.—1. The combination with a pneumatic switch-throwing mechanism, of a connecting means between the same and a moving engine, comprising a coupling in two halves adapted to be temporarily connected while the engine is moving, one half mounted on the engine and having a valve normally closed and the other half mounted along the track, one of said halves having movement on its support lengthwise the track, and means for automatically opening said valve when the two halves are connected, substantially as described.

2. The combination with a pneumatic switch-throwing mechanism, of a connecting means between the same and a moving engine, comprising a coupling in two halves, one half mounted on the engine and having a valve normally closed and the other half mounted along the track, one of said halves having movement upon its support lengthwise the track, a lock upon the two halves of the coupling adapted to hold them together temporarily, and means for automatically opening said valve when the two halves are connected, substantially as described.

3. The combination with a pneumatic switch-throwing mechanism, of a connecting means between the same and a moving engine comprising a coupling in two halves, one half mounted on the engine having a valve normally closed and the other half mounted along the track, one of said halves having movement upon its support lengthwise the track, a lock upon the two halves of the coupling adapted to hold them together temporarily, and means for automatically opening said valve when the two halves are connected, substantially as described.

4. The combination with a pneumatic switch-throwing mechanism, of a connecting means between the same and a moving engine, comprising a coupling in two halves, one half mounted on the engine and having a valve normally closed, the other half mounted along the track, and means for projecting the engine-coupling to engage the track-coupling, one of the said couplings having movement upon its support lengthwise the track, a lock upon the two halves of the coupling adapted to temporarily lock them together, and means for automatically opening the valve when the two halves are connected, substantially as described.

5. The combination with a pneumatic switch-throwing mechanism, of a coupling in two halves, one half connected with a compressed-air supply upon the engine and the other with a pneumatic switch-throwing mechanism, and means for automatically connecting the two halves while the engine is passing, substantially as described.

6. The combination with a pneumatic switch-throwing mechanism of a connecting-coupling between the same and the engine comprising two parts, one part mounted upon the engine and one alongside the track, the engine-coupling being movable to engage the track-coupling and one part of the coupling being movable upon a support along the track when in contact, substantially as described.

7. The combination with a pneumatic switch-throwing mechanism, of a connecting-coupling between the same and the engine, comprising two parts, one part mounted upon the engine and one alongside the track, the engine-coupling being movable to engage the track-coupling, one part of the coupling being movable upon a support along the track when in contact with the track, and a valve connected to the engine-coupling, and means for opening said valve while the two parts of the coupling are connected, substantially as described.

8. The combination with a pneumatic switch-throwing mechanism, of a connecting means between the same and a moving engine, comprising a coupling in two parts, one part mounted upon the engine and the other along the track, a valve in the engine-coupling, normally closed and having a projecting opening-pin, a bar on the track-coupling adapted to engage said pin when the two parts of the coupling are connected, and means for temporarily connecting the two parts of the coupling as the engine passes, substantially as described.

9. The combination with a pneumatic switch-throwing mechanism, of a connecting means between the same and a moving engine, comprising a coupling in two parts, one part mounted upon the engine and the other along the track, a valve in the engine-coupling, normally closed and having a projecting opening-pin, a bar on the track-coupling, adapted to engage said pin when the two parts of the coupling are connected, locking projections upon the track-coupling, and pivoted catches upon the engine-coupling, adapted to temporarily lock the two together, substantially as described.

10. The combination with a pneumatic switch-throwing mechanism, of a connecting means between the same and a moving engine, comprising a coupling in two halves, one half mounted on the engine and having a valve normally closed, the other half mounted along the track, one of said halves having movement upon its support lengthwise the track, locking projections upon the track-coupling, and catches upon the engine-coupling, adapted to temporarily lock the two together, substantially as described.

11. The combination with a pneumatic switch-throwing mechanism, of a connecting means between the same and a moving engine, comprising a coupling in two parts, one part mounted upon the engine, and the other along the track, a guide having overhanging flanges for the track-coupling to slide in, a valve in the engine-coupling, normally closed and having a projecting opening-pin, a bar on the track-coupling, adapted to engage said pin when the two parts are connected, locking projections upon the track-coupling, and pivoted catches upon the engine-coupling, adapted to engage the guiding-flanges to temporarily lock the two together, substantially as described.

12. The combination with a pneumatic switch-throwing mechanism, of a flanged guide located lengthwise the track, a shoe movable therein and forming one part of the coupling, a support for returning said shoe to its normal position, a shoe mounted upon the engine and connected to the air-supply and forming the other half of the coupling, means for projecting said shoe to enter beneath the flanges of the guide, and means for locking the shoes forming the coupling while in the guide, substantially as described.

13. The combination with a pneumatic switch-throwing mechanism, of a flanged guide located lengthwise the track, a shoe movable therein and forming one part of a coupling, a spring for returning said shoe to its normal position, a shoe mounted upon the engine and connected to the air-supply and forming the other half of the coupling, a valve in said latter half of the coupling which is normally closed, a valve-opening pin adapted to open the valve when the two shoes forming the coupling are locked together, and means for locking said shoes together while in the flanged guide, substantially as described.

14. The combination with a pneumatic switch-throwing mechanism, of a flanged guide located lengthwise the track, a shoe movable in said guide and forming one part of a coupling, a spring for returning said shoe to its normal position, a shoe mounted upon the engine and connected to the air-supply and forming the other half of the coupling, a pneumatic piston mounted upon the engine and carrying the shoe forming the engine-coupling, said piston having a hollow rod and a normally-closed valve in the same, and means for locking the two coupling-shoes together and for opening said valve, substantially as described.

15. A pneumatic switch-operating mechanism, comprising an air-cylinder connected to the switch-points to operate them in either direction, pipes connecting the same with coupling members located along the track, and a complementary coupling member mounted upon the engine and adapted to be momentarily connected with the fixed coupling member at will, while the engine is in motion, substantially as described.

16. A pneumatic switch-operating mechanism, comprising an air-cylinder connected to the switch-points to operate them in either direction, a piston connecting the mechanism with coupling members located along the track, a check-valve between the cylinder and each of said coupling members, a releasing-valve in said air-cylinder, set to open at a pressure below the working pressure and to close by the working pressure, said valve having a small air-escape or leakage opening, and means whereby the connection may be temporarily made from an air-supply on the engine to the pipes leading to the cylinder, substantially as described.

17. A cylinder for pneumatic switch-throwing mechanism, having a releasing-valve provided with a small leakage-hole, a spring acting on the valve to open it and set to permit closing under working pressure, a check-valve preventing backflow in the supply-pipe, and means for connecting the cylinder with an air-supply, substantially as described.

18. A releasing-valve for pneumatic cylinders, consisting of an inwardly-opening valve having a small leakage-orifice, and a spring or similar constantly-acting means, acting upon said valve to open it when the internal pressure is reduced below a certain point, substantially as described.

605,692. DRAWING INSTRUMENT. JOHN A. BENEDICT, Passaic, N. J. Filed Nov. 13, 1897. Serial No. 658,475. (Model.)

Claim.—1. A divider, compass or like instrument provided with legs, and means for maintaining them various distances apart, one of the legs being capable of flexure independent of the said means in opposite directions from its adjusted position, substantially as shown and described.

2. A drawing instrument of the class described, provided with two legs joined together, and one of which carries an inking-pen, the other being provided with a needle-point carried by a spring capable of flexure in one direction by its own resiliency, and in the opposite direction against the tension of a second spring, substantially as shown and described.

3. A drawing instrument of the class described, provided with two legs joined together, and one of which carries an inking-pen, the other being provided with a needle-point carried by a spring capable of flexure in one direction by its own resiliency, and in the opposite direction against the tension of a second spring, and a device for adjusting the springs relatively to each other, as set forth.

605,698. VALVE. JOHN L. BLACK, St. Louis, Mo., assignor to the Black Manufacturing Company, same place. Filed Oct. 11, 1897. Serial No. 654,735. (No model.)

Claim.—The combination consisting of a flexible tube, and a solid spherical body 2, said body 2 being of somewhat greater diameter than the interior of said tube, and adapted to close said interior, but to permit passage therethrough upon pressure being applied to opposite external sides of said tube, substantially as described.

605,694. PROCESS OF MAKING CYANIDS. HENRY S. BLACKMER, Mount Vernon, N. Y. Filed July 22, 1896. Renewed Apr. 21, 1898. Serial No. 678,426. (No specimens.)

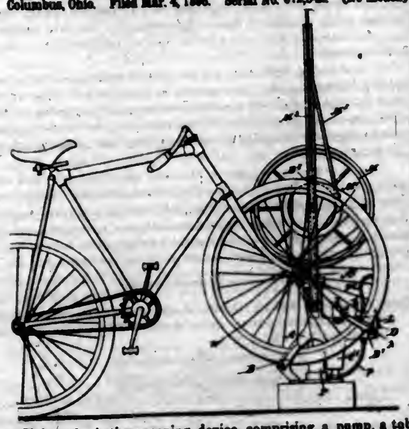
Claim.—1. The process for converting metallic sulfids into metallic cyanids, sulfocyanids, and ferrocyanids, which consists in exposing molten sulfids to the combined action of a metallic carbid and nitrogen gas substantially as described.

2. The process for converting metallic sulfids into metallic cyanids, sulfocyanids, and ferrocyanids, which consists in exposing said sulfids in a heated or molten state to the action of metallic carbids in the presence of nitrogen gas substantially as described.

3. The process for converting metallic sulfids into metallic cyanids, sulfocyanids, and ferrocyanids, which consists in passing nitrogen gas into and through a molten mass of metallic sulfid containing metallic carbid substantially as described.

4. The process for converting alkali sulfids into cyanids, sulfocyanids, and ferrocyanids, which consists in introducing into a molten both of alkali sulfid, iron carbid and passing nitrogen gas through the mass substantially as described.

5. The process for converting metallic sulfids into cyanids, sulfocyanids, and ferrocyanids, which consists in melting the metallic sulfid and introducing into the same iron carbid and nitrogen gas substantially as described.



605,695. SECONDARY BATTERY. CAMILLE BRAUN, Paris, France. Filed Dec. 26, 1896. Serial No. 617,268. (No model.) Patented in France Aug. 14, 1896, No. 260,694; in Belgium Jan. 16, 1896, No. 119,276; in England Jan. 16, 1896, No. 719, and in Switzerland Jan. 16, 1896, No. 11,572.

Claim.—1. In an electric accumulator, or storage battery, a frame having secondary frames to receive the active material, a fabric of asbestos filaments free from extraneous matter, inclosing the same, perforated plates of celluloid to inclose and support the asbestos, and cross pieces or rods, of the same material as the plates, having their ends lying in openings in the celluloid plates and secured thereto by a solvent of the celluloid, substantially as described.

2. In an electric accumulator, or storage battery, the combination with a body of active material of an inclosing fabric of asbestos, an outer covering or inclosure of perforated neutral material and cross rods, or bars, lying in openings in the active material their ends being connected to the neutral plates by a solvent of the material of which said plates are composed, substantially as described.

605,696. COIN-CONTROLLED TIRE-PUMP. LEWIS S. BROWN, Columbus, Ohio. Filed Mar. 4, 1896. Serial No. 672,542. (No model.)

Claim.—1. A tire-pumping device, comprising a pump, a tube leading therefrom and adapted to be connected with a tire, a valve interposed in said tube, a wheel-lock, connections between the wheel-lock and the valve, whereby the tire connections are broken when the wheel-lock is open, and a coin-released mechanism for controlling said parts, substantially as described.

2. A tire-pumping device, comprising a pump, a tube connecting the pump and tire, a valve interposed in said tube, a wheel-lock, connections from the valve to the wheel-lock, a lever adapted to prevent opening of said valve, and a coin-chute adapted to deliver a coin upon said lever to swing it clear of the valve, to permit the opening of the valve, substantially as described.

3. A tire-pumping device, comprising a pump, a tube connecting the pump and tire, a valve interposed in said tube, a wheel-lock, connections from the valve to the wheel-lock, a pivoted coin-operated lever, a segment-arm mounted upon the valve-stem and normally engaged by said coin-operated lever to prevent opening of the valve, and a coin-chute for delivering a coin to said coin-operated lever, substantially as described.

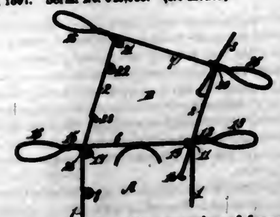
4. A tire-pumping device, comprising a pump, a tube connecting the pump and tire, a valve interposed in said tube, a wheel-lock, connections from the valve to the wheel-lock, a pivoted coin-operated lever, a segment-arm mounted upon the valve-stem and normally engaged by said coin-operated lever to prevent opening of the valve, an arm upon the valve-stem, engaging the coin-operated lever to prevent discharge of the coin until the valve is moved by hand, and a coin-chute for delivering a coin to said coin-operated lever, substantially as described.

5. A tire-pumping device, comprising a wheel-support having a pivoted locking-hook adapted to secure the wheel in place, a pump, a tube connected to the pump and adapted for attachment to a tire, a valve interposed in said tube, connections from the valve to the locking-hook, whereby the wheel is released when the valve is turned to cut off the air-supply, and a coin-operated mechanism controlling the valve, substantially as described.

6. A tire-pumping device, comprising a wheel-support having a pivoted locking-hook adapted to secure the wheel in place, a pump, a tube connected to the pump and adapted for attachment to a tire, a valve interposed in said tube, having an extended stem, connections from the valve to the locking-hook, whereby the wheel is released when the valve is turned to cut off the air-supply, a coin-operated lever, a coin-chute leading thereto, a segment-arm upon the valve-stem, normally engaging the side of the coin-operated lever, and an arm upon the valve-stem, normally extending under the coin-operated lever and stopping its swing short of the position where the coin is discharged, substantially as described.

7. A tire-pumping device, comprising a wheel-support having a pivoted locking-hook adapted to secure the wheel in place, a pump, a tube connected to the pump and adapted for attachment to a tire, a three-way valve interposed in said tube and adapted to connect the pump either with the tire connection or the open air, connections from the valve to the locking-hook, whereby the wheel is released when the valve is turned to cut off the air-supply, and a coin-operated mechanism controlling the valve, substantially as described.

605,697. PROCESS OF UTILIZING ACID SULFATES OF SODA. ROBERT R. CRAFFIELD, Gowerstone, England. Filed Dec. 20, 1897. Serial No. 663,722. (No specimens.) Patented in England Oct. 17, 1895, No. 19,530; in Belgium Apr. 27, 1894, No. 109,705, and in Germany May 11, 1894, No. 82,443.



Claim.—1. The herein-described process for treating acid sulfates of soda, by acting on their solutions with ammoniacal compounds, thereby producing mixed sulfates of ammonia and soda, and separating sulfate of soda and sulfate of ammonia therefrom by fractional crystallization.

2. The herein-described process for treating acid sulfates of soda, which consists in acting upon their solutions with ammoniacal compounds to produce mixed sulfates of ammonia and soda, evaporating the solution of said mixed salts to a specific gravity of about 1,380 at boiling temperature, to crystallize out sulfate of soda, removing the sulfate-of-soda crystals, continuing the evaporation to crystallize out the mixed salts, then dissolving the crystals of the mixed salt in cold mother-liquor to a specific gravity of 1,285 and evaporating the resultant solution to crystallize out sulfate of ammonia, substantially as described.

3. The herein-described process of treating acid sulfates of soda which consists in acting upon their solutions with ammoniacal compounds to produce mixed sulfates of ammonia and soda, evaporating the solution of said mixed salts to a specific gravity of about 1,380 at boiling temperature, to crystallize out sulfate of soda, and removing the sulfate-of-soda crystals from the solution, substantially as described.

4. The herein-described process of treating acid sulfates of soda which consists in acting upon their solution with ammoniacal compounds, to produce mixed sulfates of soda and ammonia, removing a portion of the sulfate of soda by crystallization, and crystallizing out mixed sulfates of soda and ammonia, treating said mixed sulfate crystals with cold mother-liquor, to produce a solution of a specific gravity of about 1,285, evaporating the solution to crystallize sulfate of ammonia and removing the sulfate-of-ammonia crystals, substantially as described.

605,698. TRELLIS. FRED D. CLARK, Erattsburg, N. Y. Filed Aug. 30, 1897. Serial No. 649,985. (No model.)

Claim.—1. A trellis comprising a number of frames connected in vertical series and adapted to be turned to position to increase the height of the trellis, substantially as described.

2. A trellis comprising a number of frames connected in vertical series and adapted to be turned to position to increase the height of the trellis, and means for maintaining each frame in its adjusted position, substantially as described.

3. A trellis comprising a number of frames connected in vertical series and adapted to be turned into and out of operative positions whereby, respectively, to increase or diminish the height of the trellis, and means on one of the frames for engaging a suitable support by which the trellis is maintained in an upright position, substantially as described.

4. A trellis comprising a number of frames connected in vertical series and adapted to be turned into and out of operative positions whereby, respectively, to increase or diminish the height of the trellis, and clamping devices on the lower or base frame for engaging a suitable receptacle, substantially as described.

5. A trellis comprising a number of frames connected in vertical series and adapted to be turned into and out of operative positions whereby, respectively, to increase or diminish the height of the trellis, clamping devices on the lower or base frame, and a brace-frame connecting the arm members and arch member of said lower or base frame, substantially as described.

6. A trellis comprising a number of frames connected in vertical series and adapted by being turned laterally to be brought to position for use, and means operating both to hold and to brace the frames when in this position, substantially as described.

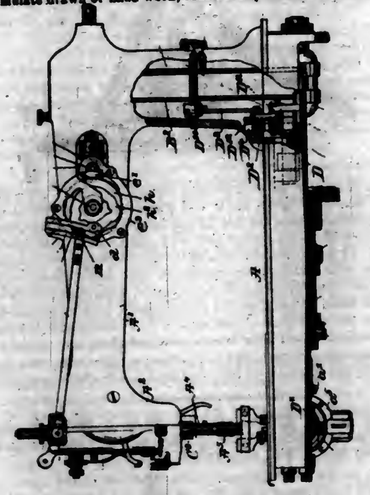
7. A trellis comprising a number of frames each composed of side arm members connected at the top by a transverse arch member, the arms of the base or lower frame having means to engage a suitable receptacle, and an arm of each remaining section having pivoted connection with the adjacent frame, substantially as described.

8. A trellis comprising a number of frames each composed of side arm members connected at the top by a transverse arch member, the base or lower frame having means for supporting the trellis in an upright position, one arm of each remaining frame having a pivotal connection with the adjacent frame and means on the other arm for retaining the frame in an upright position, substantially as described.

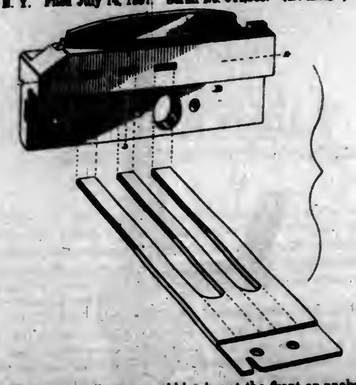
9. A trellis comprising a number of frames each composed of side arm members connected at the top by a transverse arch member, means on the base or lower frame for supporting the trellis in an upright position, one arm of each remaining frame having a pivoted connection with the adjacent frame, and means on the other arm for maintaining the frame in an upright position comprising hooks or projections for engaging eyes or recesses in the adjacent frame.

10. A trellis comprising a number of connected frames each frame consisting of a single piece of wire bent to form two parallel side arm members and a top arch member, one side arm member being provided at its bend with a shoulder, at its end with a hook or clasp, and intermediate of its ends with an eye, and the other member being provided adjacent to its bend with eyes and at its end with hooks or projections, substantially as described.

605,699. TANDEM ATTACHMENT FOR BICYCLES. THOMAS V. COWDEN, Philadelphia, Pa., assignor to Catherine A. Fischer, same place. Filed Sept. 16, 1897. Serial No. 651,993. (No model.)



Claim.—The herein-described tandem attachment consisting of a tubular socket, in which a saddle-post may be fitted and adjusted vertically, forks formed with the lower portion of said socket, a clip slidably fitted on said tubular socket, a brace-rod secured to said clip, and a second clip carried on the forward end of the rod, as and for the purpose described.

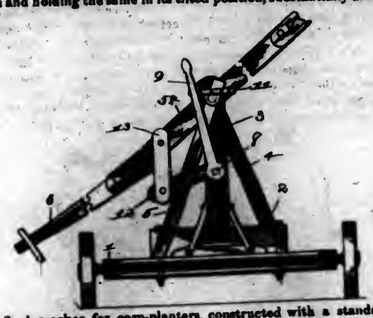


605,700. SEWING-MACHINE FOR HEMSTITCHING. GEORGE H. DIMOND, Bridgeport, Conn., assignor to The Wheeler & Wilson Manufacturing Company, same place. Filed Oct. 8, 1892. Serial No. 448,193. (No model.)

Claim.—1. A hemstitch-sewing machine, comprising a work-support, a needle bar, an eye-pointed needle, complemental stitch-forming mechanism, means to reciprocate said needle and needle-bar vertically, a gate in which said needle-bar is arranged to slide vertically, means to vibrate said gate horizontally about vertical pivots, which means includes a cam-path A^3, a pivoted arm and a link, the cam-path being shaped substantially as described to impart to the gate, needle-bar and needle while the needle is in the fabric, a movement at right angles to the edge of the hem being stitched, to thereby displace laterally from the edge of the hem some of the threads of the material being acted upon, combined with a presser-foot and a feed-dog to engage the fabric and hold it during the lateral movement of the needle, and means for actuating said feed-dog comprising pattern-cams to impart to the fabric forward and backward movements of different lengths while the needle is out of the fabric, said forward and backward movements given to the fabric being transverse to the vibratory movements of the needle, substantially as described.

2. A machine for hemstitching, containing the following instrumentalities, namely: suitable stitch-forming mechanism, including a needle and means to reciprocate it, a gate in which the needle-bar carrying the needle is reciprocated, a rotary cam having a plurality of acting surfaces, and connections actuated by said acting surfaces and located between the said cam and said gate, for imparting to said gate a plurality of movements at each rotation of said cam, whereby the needle when in the fabric will be moved to displace the threads of the fabric parallel to the line of stitching and to form openings in said fabric at right angles to the line of stitching, thereby to simulate drawn or hand work, substantially as described.

605,701. LINOTYPE-MACHINE. PHILIP T. DODGE, New York, N. Y. Filed July 14, 1897. Serial No. 644,803. (No model.)



Claim.—1. A linotype-mold having at the front an unobstructed slot or opening, and at the rear one or more filling-pieces forming part thereof to produce cavities in the base of the slug or linotype.

2. A linotype-mold having a continuous slot or opening at its front to produce a slug with an unbroken face, and having the back closed for a portion of its length with two or more openings for the admission of an ejector.

3. A linotype-mold containing an elongated slot or mold proper, its face adapted to cooperate with a series of matrices, and its rear side having a plurality of openings, in combination with an ejector, disconnected from the mold and having a plurality of fingers or blades adapted to enter and withdraw from said mold-openings, substantially as described and shown.

605,702. MARKER FOR CORN-PLANTERS. HENRY T. DONALDSON, Fillmore, Ill. Filed Apr. 5, 1898. Serial No. 676,505. (No model.)

Claim.—1. A marker for corn-planters, constructed with a standard, a beam fulcrumed in the upper end of said standard, marking-runners carried by the ends of said beam, and means for tilting said beam and holding the same in its tilted position, substantially as specified.

2. A marker for corn-planters, constructed with a standard, a beam fulcrumed in the top of said standard, arms hinged so as to swing upwardly from the ends of said standard, and marking-runners carried by the outer ends of said arms, substantially as specified.

3. An attachment for corn-planters, constructed with a standard carried by the frame of the planter in front of the driver's seat, a beam fulcrumed in the top of said standard, arms hinged to the ends of said beam so that they will fold upwardly, marking-runners carried by the outer ends of said arms, a rock-shaft passing through the standard, a hand-lever fixed to said rock-shaft, and hinged connections from said rock-shaft to the beam to allow said beam to be tilted by the operation of the hand-lever, substantially as specified.

605,703. SPINDLE-BEARING. GEORGE O. DRAPER, Hopedale, Mass., assignor to the Draper Company, same place and Portland, Me. Filed May 22, 1897. Serial No. 637,707. (No model.)

Claim.—A bolster-case provided at its upper end with a screw-thread; a bolster placed in said case and provided with a tapering bore; a spindle having a tapered pintle to enter the tapering bore of said bolster; a step for the lower end of said spindle, and a spring interposed between said step and the open lower end of said bolster, combined with an adjustable collar engaging the screw-thread at the upper end of said bolster-case, said collar cooperating with the said bolster to determine its ascent in the bolster-case under the action of said spring, and thereby regulate the fit between the tapered surface of the bolster and the tapered pintle of the spindle substantially as described.

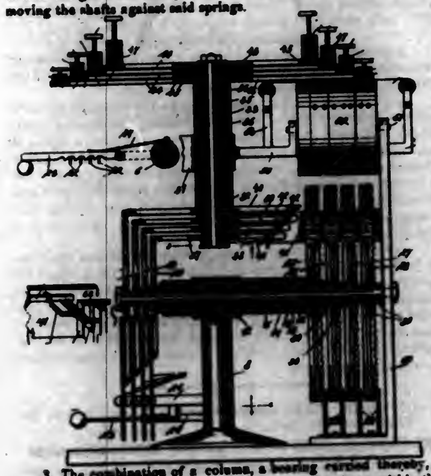
605,704. CORN MASHER AND CUTTER. JOHN ESSEGER, Chambersburg, Pa. Filed June 18, 1897. Serial No. 641,262. (No model.)

Claim.—1. In a machine of the class described, the combination of a frame, an oscillatory jaw mounted at the lower end thereof upon a pivot-bolt in said frame and provided at its upper end with a slot and at one side with a working or crushing face, a tilting jaw adjoining one end of the frame and pivoted centrally upon an adjustable pivot-bolt and provided with a working or crushing face beveled at the upper and lower end thereof, and set-screws projecting through said end wall of the face and adapted to bear upon the said tilting jaw above and below the pivotal point thereof, for limiting the tilting movement of said jaw, substantially as described.

2. In a machine of the class described, the combination of a frame, an oscillatory jaw pivotally mounted in said frame and provided at the upper end thereof with a slot and at one side with a working or crushing face and at the other side with a head, an adjustable tilting jaw acting in conjunction with the said working or crushing face of the oscillatory jaw, a crank-shaft operating in the slot of the oscillatory jaw, a cutting-blade on the frame adjoining the head of said oscillatory jaw, and a push-block acting in conjunction with said blade and jaw, substantially as described.

3. In a machine of the class described, the combination of an oscillatory jaw, and a crank-shaft for operating said jaw, a cutting-blade adapted to cut the corn forced toward it by said jaw, and a spring-actuated push-block normally resting upon the blade and adapted to force the corn toward the jaw, substantially as described.

4. In a machine of the class described, the combination of a frame, an oscillatory jaw mounted therein, a crank-shaft for operating said jaw, a cutting-blade extending transversely of the frame in juxtaposition to said jaw and adapted to cut the corn forced toward it by the jaw, and a push-block carried by a spring-arm and adapted to yield or give when the corn is pressed toward the cutting-blade, and to automatically press the remaining part of the corn-ear forward, so that it will drop between the jaw and blade, substantially as described.



5. In a machine of the class described, the combination of a frame, an oscillatory jaw mounted in said frame and provided with a table, a crank-shaft for operating the said jaw, a cutting blade or bar extending transversely of the frame and adapted to cut the ear of corn pressed toward it by the jaw, and a spring-arm projecting upward from the interior of the frame and carrying at its upper end a push-block normally resting upon the surface of the cutting-blade and adapted to press the corn toward the jaw as the said jaw recedes from the cutting-blade, substantially as described.

6. In a machine of the class described, the combination of a frame, an oscillatory jaw mounted in said frame and provided at the upper end thereof with a slot, a head at one side and a working face at the opposite side, a tilting jaw mounted upon an adjustable pivot-bolt adjoining one end of the frame and provided with a working face adapted to act in conjunction with the working face of the oscillatory jaw, a tilting table mounted on the oscillatory jaw, a crank-shaft operating in the said slot of the oscillatory jaw, a cutting-blade extending transversely of the frame adjoining the head side of the oscillatory jaw and adapted to guide the ear of corn pressed toward it by said jaw so that the lower portion thereof will drop upon the said tilting table, and a spring-arm secured to the frame and provided at the end thereof with a push-block normally resting upon the said cutting-blade and adapted to push the uncut portion of the ear of corn toward the oscillatory jaw as the latter recedes from the cutting-blade, substantially as described.

605,705. ADDING AND RECORDING APPARATUS. WILLIAM J. HOWORTH, Erie, Pa., assignor, by direct and mesne assignments, to the Erie Cash Register Company, Limited, same place. Filed Aug. 11, 1897. Serial No. 647,892. (No model.)

Claim.—1. The combination of a series of shafts inclosed one within the other and independently revolvable, registering-wheels respectively carried on said shafts, a second series of shafts inclosed one within the other and independently revolvable, gearing connecting the shafts of each series in pairs, recording-wheels respectively mounted on the members of the second series of shafts, and keys carried by the recording-wheels.

2. The combination of a series of gears, a series of shafts inclosed one within the other and independently revolvable, a gear fixed to each member of the said series of shafts and respectively meshing with the first series of gears, a spring pressing each shaft endwise to hold the gears out of engagement with each other, and means for moving the shafts against said springs.

3. The combination of a column, a bearing carried thereby, a series of shafts mounted in the bearing and inclosed one within the other and being independently movable, a gear fixed to each shaft, a lever pressing each gear, a latch-plate holding the levers, and a spring pressing the shafts respectively against the levers.

4. The combination of a series of shafts inclosed one within the other, a gear fixed to each shaft, a fingered plate held adjacent to the gears, and a hair-spring connected to each finger of the plate, the hair-springs respectively being in connection with the shafts whereby to hold the same in a normal axial position.

5. The combination of a series of shafts inclosed one within the other, a series of recording-wheels respectively fixed to the shafts, each recording-wheel comprising a hub and a rim connected by spokes, and keys carried by the rims of the wheels, and recording devices carried by the recording-wheels, some of said recording devices being capable of moving across the plane of a portion of the wheels.

6. The combination of a series of wheels turning on a common center, the wheels being of different sizes and each wheel comprising a hub and a rim connected by spokes, and keys carried by the wheels, a portion of said keys being capable of moving through the plane of a portion of the wheels.

7. The combination of a series of recording-wheels having different diameters, recording-keys carried by the wheels, and a plate movable in the vicinity of the keys so as to cover certain parts thereof.

8. The combination of a series of levers, spring-pressed parts respectively engaged thereby, a ratchet-latch coacting with the levers to hold the same, and a spring pressing the ratchet-latch.

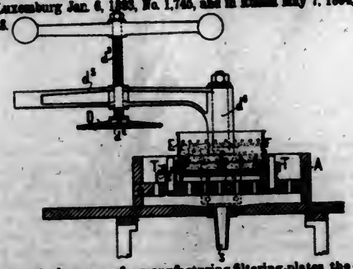
9. The combination of a plurality of recording-wheels, turning on a common center, boxes carried by each wheel, spring-pressed keys respectively movable in the boxes, and a die to which each key is attached.

10. The combination of a series of shafts revolvable on a common axis, a wheel turning with each shaft, recording devices mounted on each wheel, and springs in connection with the shafts whereby to return the wheels to a normal position.

11. The combination of a series of shafts inclosed one within the other and revolvable on a common axis, a series of wheels respectively fixed to the shafts, the wheels having varying diameters and having spokes, and recording devices carried by each wheel, the recording devices being movable transversely to the planes of the wheels, and some of the recording devices being capable of extending between the spokes of some of the wheels.

12. The combination of a series of wheels turning on a common axis and having spokes, the wheels also having varying diameters, and recording devices carried by the wheels and movable transversely to the planes thereof, some of the recording devices being capable of extending between the spokes of some of the wheels.

13. A recording-wheel having a rim, a box secured to the rim and extending transversely to the plane of the wheel, and a recording-key mounted in said box and movable through the same.



14. The combination of a series of shafts, a series of registering-wheels respectively carried on the shafts, a second series of shafts, recording-wheels respectively carried on said second series of shafts, and gearing connecting the two series of shafts in pairs so that the members of the several pairs of shafts with their corresponding recording and registering wheels will turn in unison.

15. The combination of a series of shafts inclosed one within the other, and revolvable on a common axis, registering-wheels respectively carried by the shafts, a second series of shafts inclosed one within the other and revolvable on a common axis, recording-wheels respectively carried by the second series of shafts, and gearing connecting the members of the two series of shafts in pairs.

16. The combination of a series of shafts revolubly mounted one within the other, a registering-wheel carried at one end of each shaft, the registering-wheels being located in close proximity with each other, a gear-wheel carried by each of said shafts, a second series of shafts, the members of which are revolubly mounted one within the other, a gear fixed to each shaft of said second series and respectively meshed with the first-named gears, and recording-wheels respectively carried one by each shaft of said second series.

17. The combination of a series of shafts revolubly mounted one within the other, a registering-wheel carried by each shaft of said series, expansive springs situated between the registering-wheels and maintaining the relative positions thereof, a gear-wheel fixed to each shaft of said series, a second series of shafts revolubly mounted one within the other, a gear fixed to each shaft of said second series and respectively capable of meshing with the first-named gears, means for independently sliding the shafts of said first-named series to engage the gears with each other, and recording-wheels respectively carried by the members of said second series of wheels.

605,706. APPARATUS FOR MANUFACTURING FILTERING-PLATES. LORENZ A. ENNINGER, Worms, Germany. Filed July 26, 1892. Serial No. 441,332. (No model.) Patented in Germany Apr. 26, 1892, No. 69,045; in France Apr. 27, 1892, No. 221,221; in Belgium May 18, 1892, No. 99,716; in Sweden May 23, 1892, No. 4,459; in Norway May 23, 1892, No. 2,726; in Italy May 23, 1892, LXII, 497; in England June 20, 1892, No. 11,459; in Switzerland July 2, 1892, No. 5,503; in Austria Oct. 21, 1892, No. 38,099; in Hungary Oct. 21, 1892 No. 40,807; in Luxemburg Jan. 6, 1893, No. 1,745, and in Russia May 7, 1894, No. 6,948.

Claim.—1. In a press for manufacturing filtering-plates, the combination of a casing, a perforated bottom plate below the casing, a perforated pressure-plate working in the casing, and means for conducting off the expressed liquid, the casing and bottom plate being separated to permit a filter-plate frame to be inserted between them, substantially as set forth.

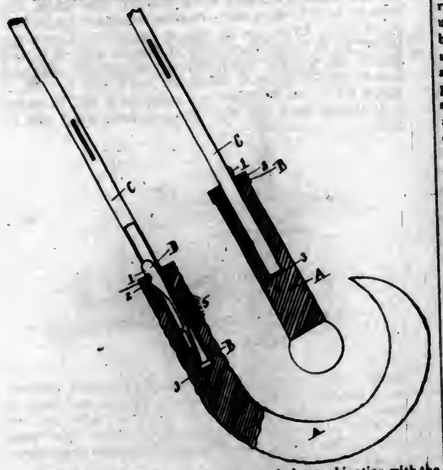
2. In a press for manufacturing filtering-plates, the combination of a perforated bottom plate G, a receiver T fitting loosely around said plate, resilient means of support for said receiver, a casing E above the receiver T, and a presser-plate working in the casing E, so as to compress the filtering material between itself and the bottom plate G, and cause the casing E and receiver T to move downwardly, substantially as set forth.

3. In a press for manufacturing filtering-plates, the combination of a movable casing and a movable receiver between which the frames of the plates are confined, a presser-plate adapted to move the casing and receiver downwardly through the working medium of the filtering material, and a perforated bottom plate on which the filtering-plate frames are pressed, substantially as set forth.

4. In a press, the combination of a casing and a bottom plate separated from the casing to permit a frame to be inserted between them, and a presser-plate adapted to reciprocate in the casing to compress material upon the frame, substantially as described.

5. In a press, the combination of a casing and a bottom plate separated therefrom to permit a frame to be inserted between them, a presser-plate within the casing, and means for reciprocating said plate within the casing and for moving it laterally to one side thereof, substantially as described.

6. In a press, the combination with a casing and a bottom plate separated therefrom to permit a frame to be inserted between them, a presser-plate adapted to be reciprocated in the casing, and means for positively holding the frame against displacement, substantially as described.

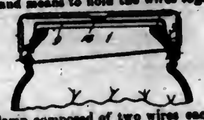


7. In a press, the combination of a bottom plate adapted to support a filter-plate frame, a receiver surrounding and normally extending above the bottom plate, a casing separated from the receiver to permit a filter-plate frame to be inserted between the two, a presser-plate within the casing, and means for moving said presser-plate vertically therein, substantially as described.

605,707. RUBBER PUMP-BUCKET. HENRY C. FREMOUR, Bridgeport, Conn. Filed Nov. 11, 1897. Serial No. 658,149. (No model.)

Claim.—A chain-pump bucket comprising a table, a hub, and a series of radial ribs or brackets integral with the said hub and table, said ribs or brackets being disposed edgewise vertically or at right angles to said table, and being highest or deepest at their inner ends and sloping thence outwardly.

605,708. DETACHABLE HANDLE FOR UMBRELLAS OR PARASOLS. SAMUEL S. FRETZ, Philadelphia, Pa. Filed Jan. 5, 1898. Serial No. 665,690. (No model.)



Claim.—1. In an umbrella or a parasol, the combination with the tubular umbrella-rod and the handle provided with a socket to receive the same, of a catch placed in the said socket, and a spring fitted within said tubular rod and provided with two projections one of which projections being intended to receive the pressure of the finger, and the other of the said projections engaging with the catch in said socket and a slot in said tubular rod through which said spring moves, substantially as described.

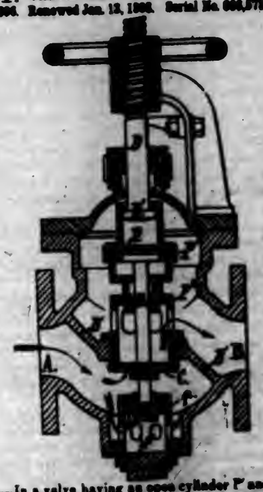
2. In an umbrella or parasol, the combination with the tubular umbrella-rod and the handle provided with a socket to receive the same, of a tube placed within the said socket, and forming a lining, a catch placed in said socket, and a spring fitted within said tubular rod and provided with two projections, one of which projections being intended to receive the finger and the other of said projections engaging with the catch in said socket and a slot in said tubular rod through which said spring moves substantially as described.

605,709. SEALING DEVICE. GEORGE W. GOMBER, Conyngham, Pa., assignor to Harry Gomber, same place. Filed Feb. 11, 1898. Serial No. 669,969. (No model.)

Claim.—1. A wire clamp for jars and the like composed of a substantially horizontal top, depending sides separating and each forming a half-circle, and means to hold the wires together, as set forth.

2. A wire clamp composed of two wires each forming one-half the clamp fitting the spiral threads of a jar and means to hold the threaded parts of the clamp together, as set forth.

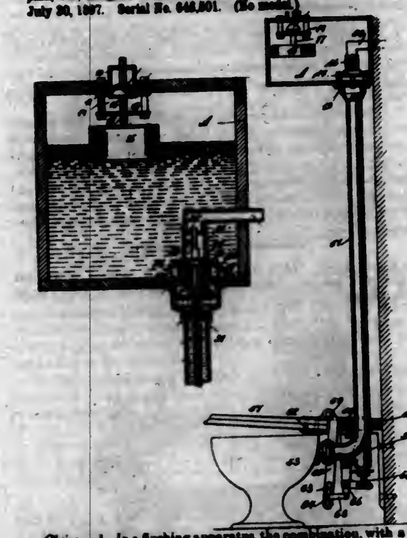
3. The combination of a jar having a screw-threaded top, a rib formed around the edge of said top, an inclined seat disposed immediately below said rib and directed outward, of a gasket resting in said seat, a top having a flange contacting with said gasket and a clamp composed of two wires bent to have a horizontal section and a curved section adapted to encircle one-half of the jar and fit said threaded top, and means for holding the two wires forming said clamp into operative relationship with each other, substantially as and for the purpose set forth.



4. As an article of manufacture, a clamp composed of two wires so bent that the middle portions thereof will provide a collar for encircling the mouth of the jar and following the threaded grooves provided in the outer surface thereof, said clamp being further provided with upwardly-extending sections and overlapping horizontally-disposed sections, and suitable means for holding said wires into operative relationship with each other, substantially as specified and for the purpose set forth.

605,710. PLUSH FABRIC. GEORGE B. GOODALL, Sanford, Me. Filed Oct. 15, 1897. Serial No. 655,271. (No specimens.)

Claim.—1. The herein-described method of producing plush fabric showing at its face a figure or design, which consists in sizing the uncut pile-loops, drying said sized fabric, depressing or crushing down below the level of adjacent pile-loops, a portion of said dried, sized, uncut loops, thus leaving some of the sized and dried loops standing and stiff and others depressed; cutting the standing loops to form the plush face; and removing the size from the fabric which softens the same and permits the previously-depressed uncut loops of pile to rise and show uncut loops in a field of cut loops in design, substantially as described.



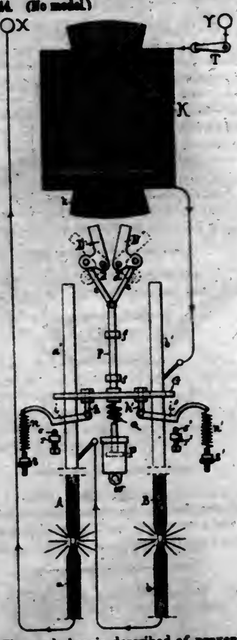
2. The herein-described method of producing plush fabric, which consists in heavily sizing the uncut pile-loops forming the face of the fabric; drying said heavily-sized pile-loops, rendering them stiff for standing against the cutting operation; cutting the loops to form the plush face; and removing the size, leaving the cut loops soft and pliable, substantially as described.

605,711. VALVE. MARIUS GROSSMARD, Marseilles, France. Filed Apr. 17, 1896. Renewed Jan. 13, 1898. Serial No. 666,578. (No model.)

Claim.—In a valve having an open cylinder P' and a body P'' integral therewith, a hollow piston P working in said cylinder, a rod Q secured to said hollow piston, a piston *p* secured to opposite end of said rod, a cylinder *p'* having openings *p''* and adapted to inclose said piston *p* and a valve-plate suitably mounted on said rod, all of said parts being combined and for the purposes substantially as described and set forth.

605,712. FLUSHING APPARATUS. HENRY HAYNES, Philadelphia, Pa., assignor of one-half to Thomas Frost, same place. Filed July 30, 1897. Serial No. 646,801. (No model.)

Claim.—1. In a flushing apparatus, the combination, with a tank, a water-supply pipe leading into the tank, the said tank being provided with an opening in its bottom, and a plate having a valve-seat supported within the tank above the opening, forming a cap for the outlet end of the supply-pipe, of a discharge-pipe fitted in the opening in the tank and provided at its top with an apertured cap having a valve-seat formed therein, connected valves, one valve being arranged to close the outlet for the water-supply pipe and the other valve being arranged to close the inlet of the discharge-pipe, one valve seating when the other is unseated, and a pull-rod connected with the valve, whereby the valves are operated, for the purpose specified.



2. In a flushing apparatus, the combination, with a tank, a water-supply pipe leading into the tank, the said tank being provided with an opening in its bottom and a plate having a valve-seat supported within the tank above the opening, forming a cap for the outlet end of the supply-pipe, of a discharge-pipe fitted in the opening in the tank and provided at its top with an apertured cap having a valve-seat formed therein, connected valves, one valve being arranged to close the outlet for the water-supply pipe and the other valve being arranged to close the inlet of the discharge pipe, one valve seating when the other is unseated, a pull-rod connected with the valve whereby the valves are operated, a tension device normally holding the pull-rod in a downward direction, causing the supply-valve to be normally seated, a lever, and a connection between the said lever and pull-rod, whereby the said rod may be forced upward against the resistance of the said tension device, as and for the purpose specified.

605,718. FIREPLACE-HEATER. JOHN H. HEITLAND, Quincy, Ill. Filed Oct. 20, 1897. Serial No. 656,514. (No model.)

Claim.—In a fireplace-heater, the combination with the heating-box, of the deflector-plate located below said box extending from a short distance from the front to the chimney-back, whereby the products of combustion may be caused to pass from front to rear beneath the box, the damper in said deflector-plate and the check having the curved toothed arm adapted to engage with the damper to adjust said check; substantially as described.

605,714. ELECTRIC-ARC LAMP. DANIEL HIGHAM, Boston, Mass., assignor to Howard H. Higham, Philadelphia, Pa. Filed Oct. 26, 1897. Serial No. 656,444. (No model.)

Claim.—1. The mode herein described of preventing excessive variations in consumption of two or more sets of electrodes connected in series and supplied from a direct-current constant-potential source, said mode consisting of extinguishing the current by opening the circuit, then bringing the points of the two or more sets of electrodes to contact, to reëstablish the current, and then separating the points of the said two or more sets of electrodes an approximately equal distance apart, substantially as described.

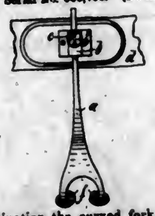
2. An electric-arc lamp for direct-current constant-potential circuits, having two or more sets of electrodes connected in series and magnetic means for controlling the current passing, in combination with means for momentarily extinguishing the current by opening the circuit at suitably frequent intervals, for the purpose described.

3. An electric-arc lamp for direct-current constant-potential circuits, having two or more sets of electrodes connected in series and magnetic means for controlling the current passing, in combination with means for momentarily extinguishing the current at suitably frequent intervals by preventing advance of the movable electrodes, substantially as and for the purpose described.

4. An electric-arc lamp for direct-current constant-potential circuits, having two or more sets of electrodes connected in series and magnetic means for controlling the movable electrodes through suitable intervening clutch mechanism, in combination with means for preventing disengagement of said clutch mechanism while current is passing, substantially as and for the purpose described.

5. An electric-arc lamp for direct-current constant-potential circuits, having two or more sets of electrodes connected in series and magnetic means for controlling the movable electrodes through suitable intervening clutch mechanism, in combination with means for momentarily extinguishing the current at suitably frequent intervals, by opening the circuit before the movable clutch mechanism reaches the position necessary to disengage the same, substantially as and for the purpose described.

6. In an electric arc lamp for direct-current constant-potential circuits, having two or more sets of electrodes connected in series,



the combination of magnetic means possessing high self-induction, for the purpose described, and acting to regulate the amount of current passing, with means for momentarily extinguishing the current by opening the circuit at suitably frequent intervals, for the purpose described.

7. In an electric-arc lamp for direct-current constant-potential circuits, having two or more sets of electrodes connected in series, the combination of series magnet-windings possessing high self-induction, for the purpose described, and acting to regulate the amount of current passing, with means for momentarily extinguishing the current by opening the circuit at suitably frequent intervals, for the purpose described.

8. In an electric-arc lamp for direct-current constant-potential circuits, having two or more sets of electrodes connected in series, the combination of series magnet-windings possessing high self-induction, for the purpose described, and acting to regulate the amount of current passing, with means for momentarily extinguishing the current at suitably frequent intervals, by preventing advance of the movable electrodes, for the purpose described.

9. In an electric-arc lamp for direct-current constant-potential circuits, the combination of three sets of electrodes connected in series and inclosed at the arcs, magnetic windings possessing high self-induction, for the purpose described, and acting to regulate the current passing, with means for extinguishing the current momentarily at suitably frequent intervals, for the purpose described.

605,715. SPECULUM. KARL HOHMANN, Neukirchen, Germany. Filed Dec. 4, 1897. Serial No. 660,795. (No model.)

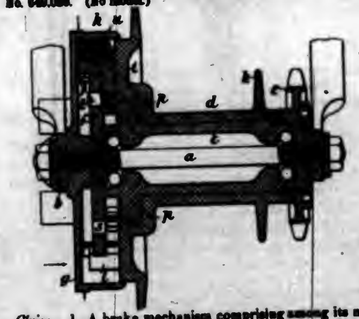
Claim.—In combination the curved fork *a*, having two hook-shaped ends *i* and a narrowed upper part *f*, the guide-piece *b*, with the thumb-screw *c* and the head-band *d*, all substantially as set forth.

605,716. TROLLEY-WHEEL. ALEXANDER F. HUMPHREY, Allegheny, Pa. Filed Dec. 9, 1897. Serial No. 661,262. (No model.)

Claim.—A trolley comprising a fork with a shaft mounted therein, a trolley-wheel mounted on said shaft, springs arranged on said shaft and adapted to retain said trolley-wheel in a central position thereon, arms pivotally secured in the upper ends of said fork and having coiled springs attached to their rear faces thereby preventing the wheel from leaving the wire, rollers mounted on the upper ends of said fork and extending above the same, said rollers assisting the trolley in passing switches arranged on the wire, and means whereby said arms can be operated to pass the trolley-wheel into or out of engagement with the wire, substantially as herein shown and described.

605,717. FILE AND BINDER. ADOLPH A. HUEBLER, St. Louis, Mo. Filed Nov. 20, 1897. Serial No. 660,112. (No model.)

Claim.—1. A file and binder, comprising covers connected by a back, and fasteners for the leaves arranged on one of the covers adjacent to the back, said fasteners consisting of bent or curved members pivoted together in a recess in the cover and having an interlocking engagement at their free ends.



2. The file and binder comprising suitable covers, a plate fastened to one cover, and fasteners for the leaves, composed of members of approximately U shape pivoted together beneath the plate and held to the latter, the free ends of the fastener members being formed to engage each other.

3. The file and binder comprising suitable covers, a plate fastened to one cover, and fasteners for the leaves, composed of members of approximately U shape pivoted together beneath the plate and held to the latter, the free ends of the fastener members being formed to engage each other, the plate being recessed at opposite sides and bent upward between the recesses to accommodate the fastener members, and the free ends of the fastener members being formed to engage each other

---

605,718. BACK-PEDALING BRAKE. JOHN R. HUBBEY and ARTHUR I. SUMMERS, Bristol, England. Filed Aug. 21, 1897. Serial No. 649,089. (No model.)

Claim.—1. A brake mechanism comprising among its members, a fixed disk provided with a friction-flange, a wheel-hub, a disk secured to said hub and provided with movable brake-blocks, a cam provided with grades for forcing said blocks into engagement with said flange and with cam-slots engaging studs on said blocks for positively withdrawing the same, a sleeve within said hub, having a limited rotary movement with respect thereto, a driving device on said sleeve, and connections between said sleeve and said cam, substantially as described.

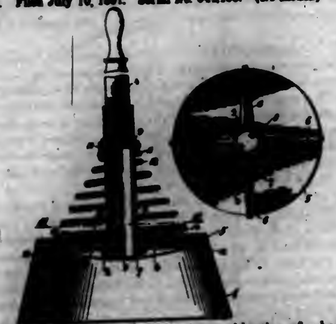
2. A brake mechanism comprising among its members, a fixed disk provided with a friction-flange, a wheel-hub, a disk connected with said hub provided with a series of guides, radially-movable brake-blocks engaging said guides and provided with studs, a cam-disk having cam-slots engaging said studs and cam-grades for engaging said blocks to force them against the friction-flange, a sleeve extending through said hub, limited rotary movement in respect thereto, a driving device on said sleeve, said sleeve being secured to said cam-disk, substantially as described.

605,719. SUSPENDER-CLASP. JOHN V. JAMES, Goldbasin, Wash., assignor to himself and John Gleave, same place. Filed Sept. 2, 1897. Serial No. 650,331. (No model.)

Claim.—1. A suspender-clasp, comprising two clamping members slotted at like ends, and hinged together near their opposite ends, a coiled spring the limbs of which engage the said members near their hinge to normally spread them apart, and a detent-hook on one member adapted to be brought into engagement with an edge of the other member, and hold the two members in clamped condition against the stress of the spring, as specified.

---

2. A clasp for suspenders, comprising clamping-sections slotted near one end to receive a hook on a suspender-band, each section having two spaced limbs which limbs are indented at opposite points, the limbs of one section being cross-slotted to loosely receive the limbs of the other section and thus provide a hinged joint between said sections, a wire spring located in the indents of opposed limbs and engaging its ends therewith to normally spread said limbs apart and a detent-hook on one section adapted for interlocking engagement with an edge of the other section to hold the limbs thereon in clamped condition and the spring-limbs compressed, as specified.



605,720. LOCK ATTACHMENT. WILLIAM S. JENKINS, Licking, Mo. Filed Oct. 6, 1897. Serial No. 654,306. (No model.)

Claim.—1. The combination of a face-plate having a slideway, a lock-plate mounted in the slideway and having two slots, one of which is L-shaped and adapted for coaction with a key, and the other of which is V-shaped, a shank mounted to rock in the face-plate, and an arm fixed to the shank and having a portion engaged in the V-shaped slot of the lock-plate,

2. The combination with a latch and keeper, of a face-plate adjacent to the latch, a lock-plate sliding on the face-plate and capable of engagement with the keeper, the lock-plate having two slots one of which is L-shaped and juxtaposed to the keyhole of the latch and the other of which is V-shaped, a shank mounted in the face-plate, and an arm fixed to the shank and engaged in the V-shaped slot of the lock-plate.

605,721. WASHING-MACHINE. HANS C. JOHNSON, Wanton, Iowa. Filed July 10, 1897. Serial No. 644,153. (No model.)

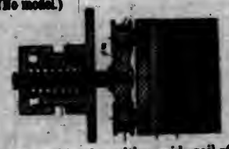
Claim.—In a washing-machine, the combination of a body having an aperture in its top, a tube loosely fitting said aperture and having a collar on its upper end and an agitating-disk on its lower end, a coiled spring disposed around the tube and located between said collar and body, a yielding gasket encircling the tube and resting on the upper surface of the body and a plate having an enlarged central aperture and an upturned flange resting on said gasket, all arranged as set forth.

605,722. GEARING. HENRY B. KEPNER, Lancaster, Pa. Filed Mar. 7, 1898. Serial No. 672,998. (No model.)

Claim.—1. A gear comprising a body portion having a groove, balls in said groove, and screws entering the latter and capped for engagement with the balls to confine the same in place, substantially as described.

2. A gear comprising a body portion having a groove, balls in said groove, and screws entered through opposite sides of the groove and capped in their confronting ends for engagement with the balls to confine the same in place, substantially as described.

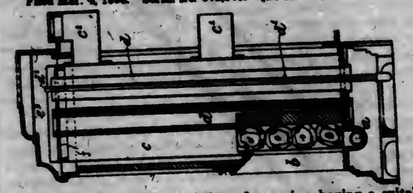
3. A gear comprising a body portion having a groove with sockets in the base thereof, balls seating in said sockets, and screws entering the groove and capped for engagement with the balls to confine the same in place, substantially as described.



4. A gear-wheel comprising a body portion having a peripheral groove, balls therein, and screws arranged in pairs entered through opposite sides of the groove and capped in their confronting ends for engagement with the balls to confine the latter in place, substantially as described.

605,723. GAME APPARATUS. CLARA L. KLAUDER, Philadelphia, Pa. Filed Sept. 1, 1897. Serial No. 650,278. (No model.)

Claim.—A game apparatus consisting of a board, sides secured around the edges of the board, ledges of greater width than the sides secured to the tops thereof, said ledges having their upper faces beveled whereby they slant upward toward the center, pins set in the central part of the board, and rings adapted to be projected from the ledges, as and for the purpose described.



605,724. BRUSH. JULES LAFAURIE, Castelmoron, and GUILLAUME GIROD-LANAURE, Monflanquin, France. Filed Dec. 13, 1893. Serial No. 616,362. (No model.)

Claim.—1. In combination with a guide-rail of any desired curvature, a flexible brush provided with rollers adapted to clamp the edges of the guide-rail and be guided thereon substantially as described.

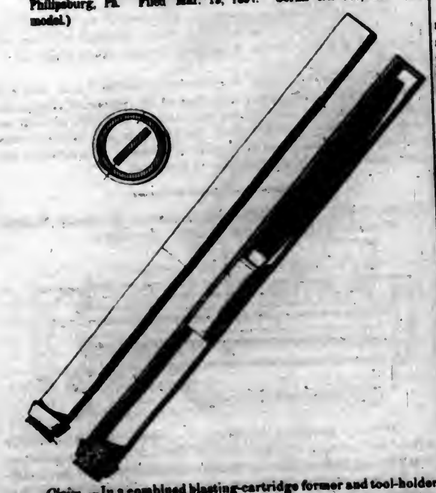
2. In combination with a guide-rail, a flexible brush provided with rollers adapted to clamp the edges of the guide-rail, said guide-rail being provided with headed pins, a frame provided with adjustable caps or sleeves within which the pins pass, and springs within the caps or sleeves pressing against the headed pins, whereby the guide-rail may yield, substantially as described.

605,725. GAS-STOVE. JOHN LANGSTAFF, Manchester, England. Filed Mar. 4, 1898. Serial No. 672,575. (No model.)

Claim.—A gas-stove consisting of a casing having a suitable burner and a fireplace located directly above the burner, a partition near the top dividing the casing into a heating-chamber and a hot-air chamber, vertical air-heating pipes passing through the heating-chamber behind the fireplace and communicating with the hot-air chamber above the partition, a perforated top to which said air-heating pipes lead, a fine screen interposed between the perforated top and the upper ends of the air-heating pipes in the hot-air chamber,

an outlet for the products of combustion at such height in the air-heating chamber as to form a column of heat around a considerable portion of the air-heating pipes, and a safety-outlet communicating with the heating chamber slightly below the partition and leading to the outside of the casing, and there provided with a valve, whereby force of explosion within the heating-chamber will be prevented from disrupting the parts, substantially as described.

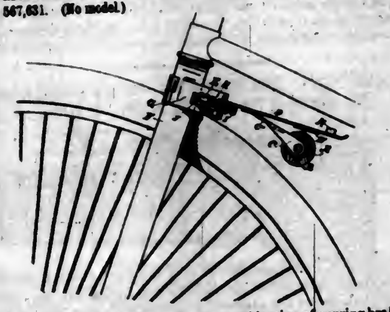
605,726. CAR-COUPLING. EDWARD B. LAUGHTER, Langhlin, Ark. Filed Dec. 30, 1897. Serial No. 664,537. (No model.)



Claim.—1. In a car-coupler the combination with the draw-head having spring-jaws pivoted therein, of means for opening said jaws comprising a rod carrying a cam adapted to operate one jaw, and means, such as a chain for connecting said cam with the rear end of the opposite jaw whereby to operate it, substantially as described.

2. In a car-coupler the combination with the draw-head of spring-jaws pivoted therein having lateral slots, a stop-block within the draw-head having tongues adapted to fit in said slots, a rod journaled in bearings on the side of the draw-head and carrying a cam, contacting with one of the jaws and means, such as a chain, for connecting the cam with the rear end of the opposite jaw, substantially as described.

3. In a car-coupler the combination with the draw-head of jaws pivoted therein having slots, a stop-block having in its forward portion outwardly-extending tongues adapted to fit in said slots, and in its rear a cut-away portion to permit lateral movement of the jaws, springs located in such cut-away portion and normally pressing the rear ends of the jaws outward, and means for forcing said rear ends inward to open the coupler, substantially as described.

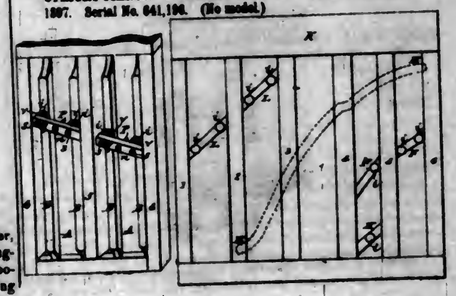


4. In a car-coupler, the combination with the draw-head having spring-jaws pivoted therein of means for opening said jaws comprising a vertically-extending rod journaled in bearings in the draw-head, a cam carried by said rod and normally contacting with one jaw, means such as a chain, connecting the cam with the rear end of the opposite jaw, a supplemental rod journaled in the draw-head, and extending horizontally outward to the side of the car, and a chain connecting said rod with the cam, whereby, in the operation of the device the jaws may be opened from the top or side of the car, substantially as described.

605,727. COMBINATION BLASTING-TOOL. GEORGE LAWS, Philipsburg, Pa. Filed Mar. 19, 1897. Serial No. 628,249. (No model.)

Claim.—In a combined blasting-cartridge former and tool-holder, the combination of the hollow squib-container handle, a retaining-shoulder thereon, a stopper therefor, a tool-holder closing the opposite end of said handle and the tool-covering cap closely engaging said tool-holder and abutting against said handle forming therewith a continuous even-surface former for the purpose set forth.

605,728. BICYCLE-BRAKE. DAVID H. LE BALLISTER, Fort Bragg, Cal., assignor, by mesne assignments, to Daniel H. Haynes and Arthur D. Stebbins, Baltimore, Md. Filed Nov. 1, 1895. Serial No. 567,631. (No model.)



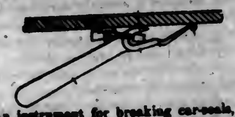
Claim.—1. In a bicycle-brake, the combination of a spring brake-lever, an arm fixed to the brake-lever, a roller carried by the arm, the brake-lever having a part engaging the roller, to retard the rotation thereof, and an operating device connected with that part of the brake-lever which engages the roller.

2. In a bicycle-brake, a flat spring-plate fixedly suspended at one end from the frame of the machine and having its opposite end free and adapted to be depressed, a second flat spring-plate secured at one end to the first-named plate and having its outer portion turned to form side lugs, a roller mounted to turn between said lugs and suspended between the tire and the under side of the first-named plate, and normally out of contact with both, and means whereby the free end of the first named plate may be depressed to force one side of the roller into contact with the tire and simultaneously bring its own wearing-surface into contact with the opposite side of the roller.

3. In a bicycle-brake, a roller turnable upon a shaft which is fixed to an elastic plate, a main plate extending substantially parallel with and fixed to and overhanging the first-named plate, having a wearing-surface upon the lower side, said roller being normally out of contact with the wearing-surface of the main plate, a transverse bar, to the central portion of which the main plate is secured, while the ends project so as to form foot-rests, and a clamp in which the transverse bar is movable horizontally and by which the bar and plate are secured to the forks of the machine.

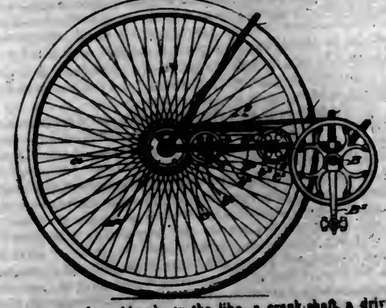
4. In a bicycle-brake, an elastic plate fixed to a transverse foot-rest and having a wearing-surface upon the lower side, a roller turnable upon a shaft which is fixed to a supplemental spring-plate, said plate being fixed to the main plate so that the roller is suspended between the main plate and the wheel of the machine, a mechanism for adjustably securing the device to the forks of the bicycle consisting of inclosing plates adapted to fit and clasp each of the forks, slots made in said plates through which the foot-rest bar extends and in which it is movable horizontally, screws turnable in nuts at the rear of the clamping-plate, the points of said screws pressing against the bar and adapted to force it against the forks so to clamp it securely thereon.

605,729. DEVICE FOR CORRECTING SOUNDING-BOARDS IN UPRIGHT PIANOS. RAPHAEL B. LETTON, Quincy, Ill. Filed June 17, 1897. Serial No. 641,196. (No model.)



Claim.—1. In a device for correcting the sounding-boards of upright pianos, the combination of the frame-standards, sounding-board, ribs, braces secured between said standards, bolts connecting said sounding-board to said braces, pressure-blocks seated between said braces and said ribs, and set-screws in said braces adapted to bear against said blocks, substantially as described.

2. In a device for correcting the sounding-boards of upright pianos, the combination of the frame-standards, sounding-board, ribs, pliable pressure-blocks arranged to bear against said ribs, and caps adapted to protect said pliable pressure-blocks, substantially as described.



3. In a device for correcting the sounding-boards of upright pianos, the combination of the frame-standards, sounding-board, ribs, pressure-blocks arranged to bear against said ribs, protecting-caps against which said pressure-blocks are seated, a brace seated against said caps, and a bolt forming a connection between said brace and said sounding-board; substantially as described.

605,730. INSTRUMENT FOR BREAKING CAR-SEALS. THOMAS A. LEATHERMAN, Laredo, Tex. Filed Jan. 26, 1898. Serial No. 667,909. (No model.)

Claim.—An instrument for breaking car-seals, the instrument having a handle provided with two legs extending in approximate parallelism with each other and disposed at an obtuse angle to the handle, one of said legs being flat and being longer than the other leg, and having its outer end provided with a roll forming a fulcrum whereon the tool may rock, the said flat leg being disposed so that the roll will engage with the surface of the car at all points along the length of the roll.

605,731. VEHICLE-PROPELLING MECHANISM. JOSEPH A. LITTLE, Lawrence, Mass., assignor of one-half to Hugh P. Simpson, same place. Filed Oct. 19, 1894. Serial No. 526,261. (No model.)

Claim.—1. In a bicycle or the like, a crank-shaft, a driving-wheel, a sheave on each, a belt connecting said sheaves, a clutch intermediate said driving-wheel and its sheave whereby rotation of the belt in one direction positively rotates the driving-wheel, free rotation of the belt in the reverse direction being permitted, a guide-roll for and to be rotated by the belt, a brake on the drive-wheel, and connections between said roll and brake, whereby rotation of the belt in the reverse direction and consequent rotation of the roll sets the brake, substantially as described.

2. In a bicycle or the like, a driving-wheel, normally operative clutch mechanism to rotate it in one direction, a crank-shaft, a driving-belt between said shaft and clutch mechanism, combined with a hand-brake for the driving-wheel, and an actuator therefor, mounted independently of the driving-wheel and crank-shaft, connections between said actuator and said belt, to positively operate the former by said belt and controlled by the direction of movement thereof, retrograde movement of the belt simultaneously releasing the propelling clutch mechanism and throwing into continuous operation the actuator of the hand-brake, substantially as described.

3. In a bicycle or the like, a driving-wheel and a driving-shaft, a sheave on each, a slack belt connecting said sheaves, and a guide-roll adjacent to and to hold the belt against each sheave, with the slack of the belt between the rolls, combined with a peripherally-grooved friction-surface rotatable with the driving-wheel, a V-shaped flexible band cooperating therewith, and connections between said band and one of the guide-rolls, to tighten the V-shaped band, when the direction of rotation of the roll is reversed, substantially as described.

4. In a bicycle or the like, a driving-wheel, a brake member secured thereto, a clutch-sheave loosely mounted upon the wheel-hub, dogs carried by said sheaves to engage the hub and rotate the wheel in one direction, a crank-shaft, a sheave fast thereon, and a slack driving-belt connecting said sheaves, combined with a compressible brake member, a guide-roll adjacent to and to hold the belt against the clutch-sheave and forming one member of a normally inoperative clutch, and a second member of said clutch connected to the compressible brake member, retrograde movement of the driving-belt reversing the direction of rotation of said guide-roll and simultaneously releasing the clutch-sheave on the driving-wheel and actuating the normally inoperative clutch to set the brake, and maintain it set, substantially as described.

5. In a bicycle or the like, a driving-wheel, normally operative clutch mechanism to rotate it in one direction, a crank-shaft, and connections between said shaft and clutch mechanism, combined with a brake for the driving-wheel, and an actuator therefor comprising a normally inoperative clutch controlled by the direction of rotation of the crank-shaft, retrograde movement of the crank-shaft simultaneously releasing the propelling clutch mechanism and throwing into operation the brake-actuator clutch, substantially as described.

6. In a coasting and braking device for cycles, the combination with a driving-belt, a clutch, and a brake, of means engaging the driving-belt and connected with the brake, for operating the same when the driving movement of the belt is reversed.

7. In a cycle, a driving-wheel and its shaft, an independent pedal-shaft, and a connection between said pedal-shaft and the driving-wheel, including a clutch and a power-transmitting member, combined with a brake, and means controlled by the pedal-shaft to operate the brake.

8. In a cycle, a driving-wheel and its shaft, an independent pedal-shaft, and a connection between said pedal-shaft and the driving-wheel, including a clutch and an endless flexible power-transmitting member, combined with a brake, and means controlled by the pedal-shaft to operate the brake.

605,732. TREAD FOR STAIRS, &c. CHARLES W. LOUER, Lowell, Mass., assignor to the American Mason Safety Tread Company, Saco, Me. Filed June 1, 1897. Serial No. 638,857. (No model.)

Claim.—1. A tread for stairs and other purposes consisting of a plate of hard metal provided with holes extending through said metal and tapering upwardly in combination with a soft material placed in said holes to produce a non-slippable surface, and grooves around each hole.

2. A tread for stairs and other purposes, consisting of a plate of hard metal provided with holes in combination with a soft material placed in said holes to produce a non-slippable surface, and means for holding a body of lead on the under side of said plate.

3. A tread for stairs and other purposes consisting of a plate of hard metal provided with holes extending through said metal and tapering upwardly in combination with a soft material placed in said holes to produce a non-slippable surface, means for holding said soft material in place, and longitudinal and transverse grooves between said holes.

4. A tread for stairs and other purposes consisting of a plate of hard metal provided with holes extending through said metal and tapering upwardly in combination with a soft material placed in said holes to produce a non-slippable surface, means for holding said soft material in place, longitudinal and transverse grooves between said holes, and means for holding a body of lead on the under side of said plate.

605,733. CUTTER. LOUIS MAUK, Canyon City, Tex. Filed Sept. 3, 1897. Serial No. 650,522. (No model.)

Claim.—1. The combination in a cutter of the upper and lower hinged sections, each section carrying two halves of the journal-bear-

ings, supports for said lower section, the support on one side forming clamps to clamp it to the edge of a table, and the supports on the opposite sides having flanges and adapted to be screwed to the surface of the table, one of said supports on each side extending above the upper section to receive a clamping-bolt to retain the said sections in position, and the other two supports extending above the lower section forming guides and stops for the upper section, against lateral pressure from the disk said disk being mounted upon a shaft in said bearings, all arranged for joint operation as set forth.

2. The combination in a cutter such as described having the upper and lower sections supports for the lower sections, the cutter-disks carried in the journals of said sections, the spindle of each disk having a removable sleeve, said sleeve being screw-threaded on the end for the interchange of cutter-disks, said disks having corresponding female screw-threads in their hubs, and adjustable on the spindle, and provided with adjustable cutter-knives the knives resting in slanting grooves, the backs of said grooves forming supports for the knives whereby the strain is taken from the holding-screws, the upper sections being secured from lateral strain by the said support, substantially as set forth.

605,784. TAKE-DOWN GUN. WILLIAM MARSH, New Haven, Conn., assignor to the Winchester Repeating Arms Company, same place. Filed Nov. 22, 1897. Serial No. 659,269. (No model.)

Claim.—1. In a take-down gun, the combination with a gun-frame having an internally-threaded barrel-receiving opening, of a gun-barrel having its butt-end threaded, and an internally and externally threaded normally-fixed take-up sleeve mounted upon the threaded butt-end of the gun-barrel, taking into the threads of the said barrel-receiving opening and normally fixed upon the barrel but adjustable thereupon for taking up wear.

2. In a take down gun, the combination with a gun-frame having an internally-threaded barrel-receiving opening, of a gun-barrel having its butt-end threaded, and an internally and externally threaded normally-fixed take-up sleeve mounted upon the threaded butt-end of the gun-barrel, taking into the threads of the said barrel-receiving opening, and means for normally holding the said sleeve against rotation upon the said barrel upon which it is turned only for taking up wear.

3. In a take-down gun, the combination with a gun-frame, having an internally-threaded barrel-receiving opening, of a gun-barrel having its butt-end threaded; and a normally-fixed take-up sleeve internally threaded for mounting upon the gun-barrel, and externally threaded for taking into the threads of the said opening, the external threads of the sleeve being coarser in pitch than the internal threads thereof.

4. In a take-down gun, the combination with a gun-frame having an internally-threaded barrel-receiving opening, of a gun-barrel having its butt-end threaded, and a normally-fixed take-up sleeve internally threaded for mounting upon the gun-barrel, externally threaded for taking into the threads of the said opening, and having an annular locking-shoulder formed at its forward end and engaged for normally locking the sleeve against rotation.

5. In a take-down gun, the combination with a gun-frame having an internally-threaded barrel-receiving opening, of a gun-barrel having its butt-end threaded, a normally-fixed take-up sleeve internally threaded for mounting upon the butt-end of the barrel and externally threaded for taking into the threads of the said opening, and formed at its forward end with an annular shoulder, and a dog engaging with the said shoulder for locking the sleeve against rotation and in any desired position of adjustment.

6. In a take-down gun, the combination with a gun-frame having an internally-threaded barrel-receiving opening, of a gun-barrel having its butt-end threaded, a tubular magazine, a yoke uniting the butt-end of the barrel and the rear end of the magazine, a take-up sleeve internally threaded for being mounted upon the butt-end of the barrel, and externally threaded for taking into the threads of the said opening, and a dog adapted to engage with the sleeve for locking the same in any desired position of adjustment, and located in a slot formed in the rear face of the said yoke.

7. In a take-down gun, the combination with a gun-frame having an internally-threaded barrel-receiving opening, and shaped at its forward end to form a recoil-face, of a gun-barrel and a tubular magazine, a yoke for uniting the butt-end of the barrel and the rear end of the magazine, and having a recoil-face conforming to that of the gun-frame, a normally-fixed take-up sleeve internally-threaded for being mounted upon the butt-end of the barrel and externally threaded for taking into the threads of the said opening and a stop projecting forward from the recoil-face of the gun-frame for limiting the rotation of the gun barrel with respect to the gun-frame in assembling the gun.

8. In a take-down gun, the combination with a gun-frame having an internally-threaded barrel-receiving opening, of a gun-barrel having an externally-threaded butt-end, a tubular magazine, a yoke uniting the butt-end of the barrel with the rear end of the magazine, and having its rear face conformed to the front face of the frame, a normally-fixed take-up sleeve internally threaded for mounting upon the gun-barrel and externally threaded for taking into the threads of the said barrel-receiving opening, a dog mounted in a slot formed in the rear face of the yoke, engaging with the sleeve for locking it against rotation, and formed with a stop-recess, and a stop projecting from the forward face of the gun-frame and entering the said stop-recess to limit the movement of the yoke, barrel and magazine in assembling the gun.

9. A gun provided with a cartridge-chamber the rear portion of which is located in the frame of the gun and formed with one or more extractor-receiving slots, the remaining or forward portion of the cartridge-chamber being located in the butt-end of the gun-barrel which may be removed from the gun-frame without disturbing the said rear portion of the said cartridge-chamber.

10. In a gun, the combination with the frame thereof, of a ring located within the said frame, forming the rear portion of the cartridge-chamber and furnished with one or more extractor-receiving slots, and a removable gun-barrel containing the remaining portion of the cartridge-chamber, and abutting against the forward face of the said ring when in its home position.

11. In a take-down gun, the combination with a gun-frame having a threaded barrel receiving opening and a threaded tubular magazine-opening, of a gun-barrel adapted to be entered into and secured within the said barrel-opening, a magazine threaded for entrance into the said magazine-opening and formed with an annular drawing-shoulder located at a right angle to the longitudinal axis of the magazine, a yoke rigidly secured to the barrel and having a magazine-passage for the passage through it of the magazine, and engaged by the said drawing-shoulder of the magazine for being drawn solidly against the gun-frame when the magazine is turned into its home position.

12. In a take-down gun, the combination with a gun-frame having a threaded barrel-receiving opening, and a tubular-magazine opening formed with interrupted threads, of a gun-barrel adapted to be inserted into and secured within the said barrel-opening and a normally-fixed take-up sleeve internally threaded for being mounted upon the butt-end of the barrel and externally threaded for taking into the threads of the barrel-receiving opening, a tubular magazine having its rear end formed with interrupted threads for coaction with the interrupted threads of the said magazine-opening, and a yoke uniting the butt-end of the barrel with the rear end of the magazine.

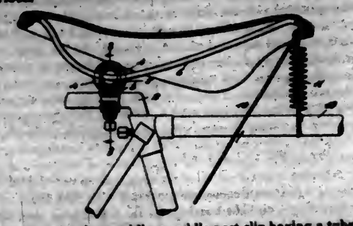
13. In a take-down gun, the combination with a gun-frame having a threaded barrel-receiving opening, and a tubular-magazine opening formed with interrupted threads, of a gun-barrel adapted to be inserted into and secured within the said barrel-opening, and a tubular magazine having its rear end formed with interrupted threads, and also with an annular drawing-shoulder located in a plane intersecting the longitudinal axis of the magazine at a right angle, a yoke firmly connected with the barrel and having a magazine-passage through which the magazine passes and which is formed with segmental drawing-shoulders separated by clearance-spaces, the said annular shoulder of the magazine and the said segmental shoulders of the yoke coacting to draw the lower end of the yoke solidly against the lower portion of the gun-frame when the magazine is turned into its home position.

14. In a tubular-magazine gun, the combination with the barrel and tubular magazine thereof, of a band embracing the said magazine and barrel a tie interposed between the barrel and magazine between the arms of the band, and having its upper face recessed for the clearance of the barrel and its lower face recessed for the clearance of the magazine, two screws respectively entering the opposite ends of the said tie and engaging with the arms of the band for drawing the same together, and at their inner ends emerging into the said upper recess and entering notches formed in the barrel for preventing the band from moving.

15. In a tubular-magazine gun, the combination with the barrel thereof, of a tubular magazine, a magazine-plug located in the forward end of the magazine, and a pin-lever mounted in the plug in which it is longitudinally movable and provided for turning the magazine into its home and take-down positions.

16. In a tubular-magazine gun, the combination with the barrel thereof, of a tubular magazine, a magazine-plug located in the forward end of the magazine, a pin passing diametrically through the plug in which it is longitudinally movable and provided for turning the magazine into its home and take-down positions and a spring for controlling the position of the said pin-lever.

17. In a tubular-magazine gun, the combination with the barrel thereof, of a tubular magazine, a magazine plug located in the forward end of the magazine, and formed with a diametric pin-lever hole, the ends of which are counterbored, a longitudinally-movable pin-lever located in the said hole in which it is movable, and a spring mounted in the said lever, and adapted at one end to spring into the counterbored ends of the hole for holding it in its operating and retired positions.

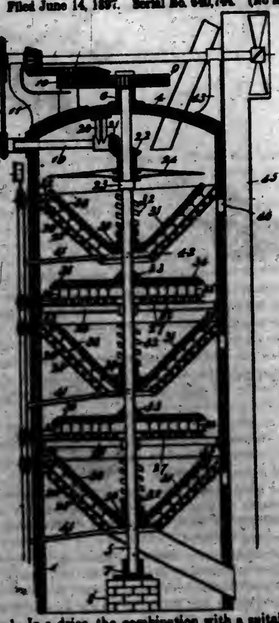


18. In a tubular-magazine gun, the combination with the barrel thereof, of a tubular magazine, a magazine-plug located in the forward end of the magazine, a lever mounted in the said plug for rotating the magazine, and a stop-ring mounted upon the plug and engaging with the barrel which prevents it from rotating upon its own axis and coacting with the plug to limit the rotation of the magazine in one direction or the other.

19. In a take down gun, the combination with a gun-frame having an internally-threaded barrel-receiving opening, and shaped at its forward end to form a recoil-face, of a gun-barrel and a magazine, a yoke for uniting the butt-end of the barrel and the rear end of the magazine, and having a recoil-face conforming to that of the gun-frame, and an internally and externally threaded normally-fixed take-up sleeve mounted upon the threaded butt end of the gun-barrel, and taking into the threads of the said barrel-receiving opening, and made adjustable for performing the twofold function of compensating for wear falling upon the internal threads of the opening, and upon the external threads of the sleeve, and upon the two recoil-faces.

605,785. VEHICLE-BRAKE. FRANK H. MATHS, Denver, Colo. Filed Jan. 26, 1897. Serial No. 619,993. (No model.)

Claim.—1. In a bicycle, a saddle-support, comprising a clip provided with a tubular portion having opposite openings, and a rocking shaft mounted in the tubular portion of the clip, the seat-spring being adapted to be secured in the rock-shaft and project out through the openings of the tubular portion of the clip, substantially as and for the purpose set forth.



2. In a bicycle, a seat-support, comprising a clip provided with a tubular portion having opposite openings, and a tubular rocking shaft mounted in the tubular portion of the clip and provided with opposite openings, said openings being smaller than the openings of the tubular portion of the clip, the said shaft being slitted longitudinally and having one end threaded to receive a nut, substantially as described.

3. In a bicycle, a saddle, a saddle-post clip having a tubular portion provided with opposite slot-openings, a rocking and clamping clip in said tubular portion and having openings through which the saddle-spring extends, the said openings being smaller than those of the tubular portion of the clip, a brake designed to be engaged with a portion of a wheel of a bicycle, and a connection between said brake and one end of the saddle, substantially as specified.

4. In a bicycle, the combination with the rear axle having a bearing between the hub of the wheel and a member of the fork, of a saddle, a clip having a rocking shaft in which the spring of the saddle is secured, a strap engaging the bearing of the axle, and a connection between the forward end of the saddle and the strap, substantially as described.

605,736. DRYING APPARATUS. ANDREW J. MILLER, Metamora, Ind. Filed June 14, 1897. Serial No. 640,744. (No model.)

Claim.—1. In a drier, the combination with a suitable housing of a rotatable shaft mounted therein, a spreader and radial vertically-inclined arms keyed on said shaft, said arms carrying blades or agitators, an inwardly-inclined hollow floor having heating-coils therein, said floor being open at its center, and means for operating the foregoing devices, as set forth.

2. In a drier, the combination with a suitable housing of a rotatable shaft vertically mounted in the housing, a spreader and radial arms vertically inclined carrying blades or agitators keyed to said shaft, an inwardly-inclined hollow floor having heating-coils therein, said floor being open at its center, horizontal arms carrying spreaders or agitators, a horizontal floor having heating-coils therein, and means to operate the foregoing devices, all arranged as set forth.

3. In a drier, the combination with a suitable housing of a rotatable shaft therein, a hopper for the admission of the grain, a horizontal spreader and arms radially and vertically disposed, said arms

carrying agitators and keyed to said shaft, floors cooperating with said agitators and separate and independent means to rotate respectively the spreader and the radial arms, all arranged as set forth.

4. In a drier, the combination with a suitable housing of a rotatable shaft vertically mounted therein, a hopper for the grain, radial arms vertically disposed carrying agitators and keyed to said shaft, floors cooperating with said agitators, and means to actuate the foregoing devices consisting of a crank-shaft carrying beveled gearing operating said rotatable shaft and a sprocket and chain acting on bevel-gearing operating the spreader, all arranged as set forth.

5. In a drier, the combination with a suitable housing of a rotatable shaft vertically mounted therein, a series of inclined and horizontally-disposed floors, a series of rotating arms keyed to said shaft and carrying agitators designed to cooperate with said floors, an air-shaft cooperating with said housing and an exhaust-fan mounted in said shaft and adapted to withdraw the moisture-laden atmosphere from said housing, all operatively arranged as set forth.

6. In a drier, the combination with a suitable housing of a rotatable shaft journaled therein, a horizontal spreader loosely mounted on said shaft, and means to lock the spreader in operative condition, radial arms keyed to said shaft carrying agitators, floors designed to cooperate with said agitators, and means to operate the foregoing devices, all arranged as set forth.

7. In a drier, the combination with a suitable housing of a horizontal spreader-disk, a series of radial arms carrying agitators, means to simultaneously adjust and secure in position all of said blades at any desired angle, and means for imparting greater speed to the disk than that imparted to the agitators, all arranged as set forth.

605,737. CAR-COUPLING. CHARLES R. MOORE and JOHN DOYLE, Chicago, Ill. Filed Aug. 12, 1897. Serial No. 647,967. (No model.)

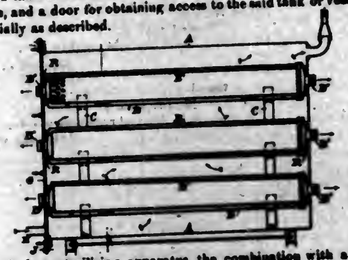
Claim.—1. A coupler, having a jaw, a jaw-recess, a ledge at the bottom of the jaw-recess, and a fork arranged to straddle the jaw-recess and confine the jaw of a counterpart coupler; substantially as and for the purposes specified.

2. A coupler having a jaw, a jaw recess, and a tapering fork arranged to straddle the jaw-recess and pinch the jaw of a counterpart coupler whereby the jaws are forced together laterally; substantially as and for the purposes specified.

3. A coupler having a jaw, a jaw-recess, a ledge at the bottom of the jaw-recess, and a tapering fork arranged to straddle the jaw-recess and confine the jaw of a counterpart coupler, substantially as and for the purposes specified.

4. The combination with a coupler stem comprised of longitudinally-adjustable sections, of a resilient ball, and a ball socket or bracket whereby the stem is attached to the car, substantially as and for the purposes specified.

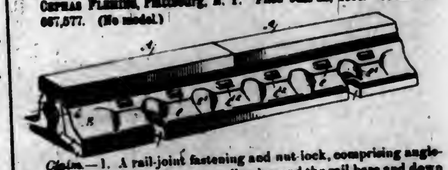
5. The combination, with a coupler-stem, of a resilient ball, and a ball-socket: substantially as and for the purposes specified.



6. The combination with a coupler-stem, of convex follower-disks, an interposed spring, and a suitable pocket for said disks and spring: substantially as and for the purposes specified.

7. The combination with a coupler-stem of a resilient ball, and a bracket having a ball-socket and provided with a horizontally-projecting ledge in advance of the ball-socket, substantially as and for the purposes specified

8. The combination with a coupler having a jaw and a jaw-recess provided at its bottom with a ledge to support the jaw of a counterpart coupler, of a drop-fork arranged to straddle the jaw-recess and confine the jaw of the counterpart coupler, and a horizontally-projecting ledge arranged to support the stem of the coupler adjacent to its point of attachment to the car: substantially as and for the purposes specified.



605,738. STERILIZING APPARATUS. ALFRED MOLET, Lyons, France. Filed Dec. 20, 1897. Serial No. 662,667. (No model.)

Claim.—1. In a sterilizing apparatus, the combination with a suitable tank or vessel having a steam-inlet and a steam-outlet, of a plurality of perforated and jacketed cylinders suitably supported within said tank or vessel and having their ends open to the outer atmosphere, and a door for obtaining access to the said tank or vessel, substantially as described.

2. In a sterilizing apparatus, the combination with a suitable tank or vessel having a steam-inlet and a steam-outlet, of a plurality of perforated and jacketed cylinders removably supported within the tank or vessel and each cylinders provided with hollow end extensions which extend through the side walls of the tank or vessel, and a door for obtaining access to the interior of the said tank or vessel.

605,739. RAIL-JOINT AND NUT-LOCK. MICHAEL MULLINS and CEPHAS FLEMING, Plattsburg, N. Y. Filed Jan. 22, 1898. Serial No. 667,577. (No model.)

Claim.—1. A rail-joint fastening and nut-lock, comprising angle-iron fish-plates having a foot extending beyond the rail-base and down toward the tie, and having spike-receiving notches in the outer edge, one of said plates having squared bolt-head recesses about its bolt-holes, and the other plate having an outwardly-projecting rib or lip at its upper edge, and a nut locking plate fitting the angle of the latter fish-plate with its upper edge beneath the rib or lip and having squared recesses adapted to receive the nuts on the bolts, and with the walls thereof removed to expose the upper outer corner of the nuts, the lower flange of the nut-locking plate having notches corresponding with those in the fish-plates to receive the spikes, and also having an under concave groove extending longitudinally, substantially as described.

2. A rail-joint, having a nut-lock comprising angle-iron fish-plates having a foot extending beyond the rail base and down toward the tie, and having spike-receiving notches in their outer edges, one of said plates having squared bolt head recesses about its bolt-holes, and the other plate having an outwardly-projecting rib or lip at its upper edge, and a nut-locking plate fitting the angle of the latter fish-plate with its upper edge beneath the rib or lip, and having squared recesses adapted to receive the nuts on the bolts, the lower flange of the nut-locking plate having notches corresponding with those in the fish-plates, to receive the spikes, substantially as described.

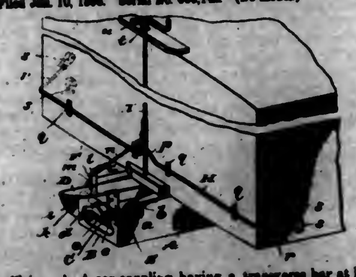
605,740. PADLOCK. JAMES MURPHY, Terryville, Conn., assignor to the Eagle Lock Company, same place. Filed Dec. 28, 1897. Serial No. 663,139. (No model.)

Claim.—1. In a padlock, the combination with the case, of a shackle pivoted therein, said shackle provided at its pivot end with a locking-lug and at its nose with a locking-notch, a tumbler also pivoted in the said case and adapted to engage with the nose of the shackle, and a locking-guard pivotally mounted in the case and adapted to be turned by the key and formed with two oppositely-extending arms, one of which is engaged by the locking-lug of the shackle and the other coupled with said tumbler for moving it, substantially as described.

2. In a padlock, the combination with the case, of a shackle pivoted therein, said shackle provided at its pivot end with a locking-lug and at its nose with a locking-notch, a tumbler also pivoted in said case and adapted to engage with the nose of the shackle, and a locking-guard pivotally mounted on the key-hub and so as to be turned by the key and formed with two oppositely-extending arms, one of which is engaged by the locking-lug of the shackle and the other end projecting over said tumbler with which it is coupled, substantially as described.

3. In a padlock the combination with the case thereof, of a shackle pivoted in the case and provided at its pivot end with a locking-lug and at its nose with a locking-notch, of a tumbler also pivoted in said case, and formed with a flange at its upper end for engagement with the locking-notch in the shackle, and with an inclined slot, a locking-guard also mounted in the case for movement by the key, said guard formed at opposite sides with arms one of which is adapted to engage with the locking-lug and the other provided with a stud to engage the inclined slot in the tumbler, and a spring, the tendency of which is to hold the locking-guard in its normal position, substantially as described.

605,741. STRAIN-INSULATOR. LOUIS MCCARTHY, Boston, Mass. Filed Jan. 18, 1898. Serial No. 667,041. (No model.)

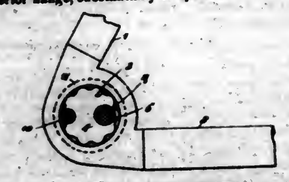


Claim.—1. An insulator comprising metallic portions separated from each other by interposed insulating material, a case, as 7, secured to the projecting end of one of said connections outside said insulating material, a sleeve secured at one end within said case and provided with a screw-threaded bolt whereby as the sleeve is turned the bolt may be screwed into or out of the sleeve to tighten or loosen the supporting-wire, substantially as described.

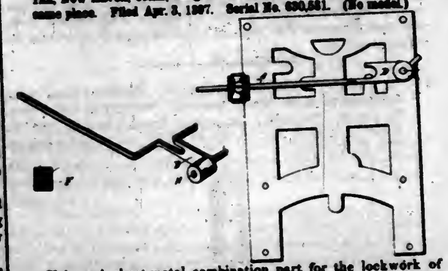
2. In an insulator the combination of metallic portions separated from each other by interposed insulating material, the case 7 having the inwardly-projecting flange 8, the sleeve 6 and bolt 9, substantially as described.

3. A strain-insulator comprising metallic portions separated from each other by interposed insulating material, a coupling member connected with a projecting part of one of said metallic portions outside of the insulating material by a swivel-joint, and a connector having an adjustable screw-threaded union with the said coupling member, substantially as described.

605,742. CAR-COUPLING. FRANCIS MCFARLANE, Iroquois, S. D. Filed Jan. 10, 1898. Serial No. 666,142. (No model.)



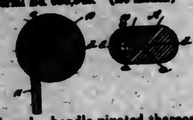
Claim.—1. A car-coupling having a transverse bar at its front end and vertical sides extending above said end, the transverse bar rounded at *c* and the side cut away at *b*, and a wearing-plate detachably applied to the front end on the inside thereof, in combination with a hook provided with a rounded inner and a rounded under side and a right-angled plate attached to the inner side of the hook.



2. A car-coupling provided with a vertically-movable hook, a shaft having a crank thereon and a chain attached to said crank, in combination with a hook connected to said chain and having an eye *w* and an eye *w'* in the body thereof, a tongue connected to the eye *w'* of the hook and engaging the eye *w* at its free end and a guard surrounding the body of the hook and the tongue.

605,743. CHAIN-ADJUSTING DEVICE. ALEXANDER PERVIER, New York, N. Y. Filed Sept. 21, 1896. Serial No. 606,503. (No model.)

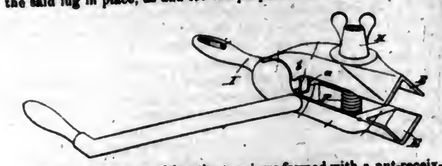
Claim.—In a bicycle, a connection between the lower bar of the frame and a member of the rear fork, said connection having a circular opening, an annular flange on the wall of said opening intermediate of the sides of the connection, the said flange being provided with transverse notches, a pair of disks inserted in the opening, one at one side and the other at the other side of the connection, each disk having an annular flange bearing on the outer surface of its side of the connection and each disk having a hole eccentrically through it, and a screw passing through an opening in the periphery of one disk and engaging with a tapped opening near the periphery of the other disk, the said screw also engaging in one of the notches of the interior flange, substantially as specified.



605,744. HAMMER FOR STRIKING-CLOCKS. WILSON R. POTTER, New Haven, Conn., assignor to the New Haven Clock Company, same place. Filed Apr. 3, 1897. Serial No. 630,581. (No model.)

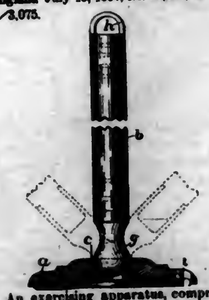
Claim.—A sheet-metal combination part for the lockwork of striking-clocks, the said part comprising a body portion, a long hammer-arm formed integral with the said body portion with which it is parallel, a lifting-finger formed integral with the said body portion and bent inward at a right angle thereto, a stop also formed integral with the said body portion and bent inward at a right angle thereto in the same direction as the said lifting-finger, an independently-formed hammer mounted upon the said hammer-arm, and an independently-formed hub rigidly secured by upsetting its reduced inner end, to the outer face of the said body portion, and providing a long bearing for the stud on which the combination part is hung, and on which it oscillates.

605,745. HANDLE. FREDERICK READ, Brooklyn, N. Y. Filed Oct. 27, 1897. Serial No. 656,548. (No model.)



Claim.—A ball, and a handle pivoted thereon eccentrically and having a preponderance of material on the same side of the pivot as the center, the material being so disposed that the diameter through the pivot shall be longer than a line drawn through the handle at the pivot perpendicular to the said diameter, whereby the fingers of the user have a purchase to press inward on said diameter to hold the ball adjacent to the palm.

605,746. WRENCH. WALTER H. ROBBINS, New York, N. Y., and EDWARD J. LAWLESS, Orange, N. J. Filed Dec. 9, 1897. Serial No. 661,205. (No model.)



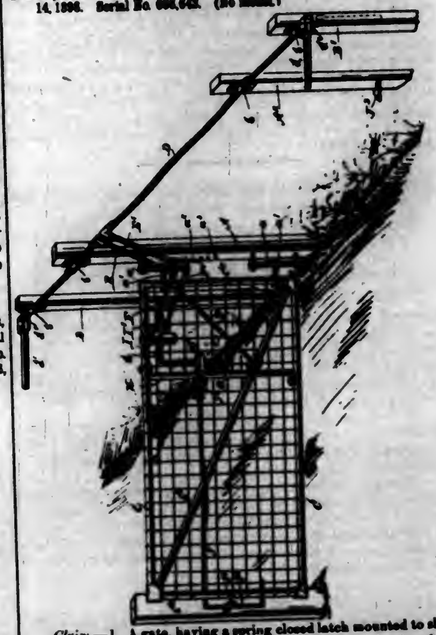
Claim.—1. A wrench provided with two jaws, one of said jaws being cast in one piece with converging sides forming one half of a nut-receiving socket, a partition flush with the opposite edges of said sides and forming a vise-surface and a rear wall for the nut-receiving socket, flanges at its rear end and separated from each other and an undercut curved socket between said flanges, and the other jaw being cast also in one piece with correspondingly-shaped sides and partition, whereby the other half of the nut-socket and the other vise-surface are provided, and at its rear end with a central curved lug fitting in the socket between said flanges, there being provided ad-

justing means for said jaws, which means prevents longitudinal movement of one jaw with respect to the other, whereby to securely hold the said lug in place, as and for the purpose set forth.

2. A wrench comprising the two jaws formed with a nut-receiving socket and a partition extending across each jaw and flush with the edges of the same, one of said jaws having side flanges separated from each other and having formed between them a curved undercut socket, a steadying-handle integral with said jaw and extending rearwardly from the point where the said socket is located, a crank-handle integral with said jaw and extending laterally therefrom at a point in advance of said socket, and the other jaw being formed with a curved lug extending from its rear end and removably received in said socket and with a curved surface on each side of said lug, said curved surfaces having bearing upon the said flanges, and a spring-encircled adjusting-bolt inserted through said jaws and preventing longitudinal movement of either jaw with respect to the other and the removal of the said lug from its place, as and for the purpose set forth.

605,747. EXERCISING APPARATUS. STANISLAW SACHS, Berlin, and HERMANN JAFFÉ, Parchim, Germany. Filed Oct. 16, 1897. Serial No. 655,469. (No model.) Patented in Germany Dec. 12, 1896, No. 94,583; in England July 13, 1897, No. 16,057, and in Austria Aug. 26, 1897, No. 47/3,075.

Claim.—1. An exercising apparatus, comprising a heavy base-plate having a flat under side, and provided with a central circular opening therethrough, having a thickened rounded mouth upon its upper side; of a pole or stock having a spherical knob at one end adapted to rest in the mouth of said opening, and have a universal movement therein, the weight of said pole or stock or the pressure imparted thereto by the operator, serving to hold said knob in said opening, substantially as and for the purposes described.



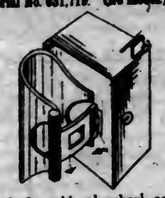
2. An exercising apparatus comprising a heavy base-plate, having a flat under side, and a soft annular ring partially embedded in said flat under side; and provided with a central circular opening therethrough having a thickened rounded mouth upon its upper side; of a pole or stock having a spherical knob at one end adapted to rest in the mouth of said opening, and have a universal movement therein, the weight of said pole or stock or the pressure imparted thereto by the operator, serving to hold said knob in said opening, substantially as and for the purposes described.

3. An exercising apparatus comprising a heavy base-plate having a flat side, and an opening therethrough near its periphery for suspending said plate from a hook or the like in some upright; and provided with a central circular opening having a thickened rounded mouth upon its other side; of a pole or stock having a spherical knob at one end adapted to rest in the mouth of said opening and have a universal movement therein while being used by the operator, substantially as described.

4. An exercising apparatus comprising a heavy base-plate having a flat under side, and provided with a central circular opening therethrough having a thickened rounded mouth, upon its upper side; of a pole or stock having a spherical knob at one end adapted to rest in the mouth of said opening, and have a universal movement therein, the weight of said pole or stock or the pressure imparted thereto by the operator, serving to hold said knob in said opening, and a jointed hand-grip upon the other end of said pole or stock, substantially as and for the purposes described.

5. An exercising apparatus comprising a heavy base-plate having a flat under side, and provided with a central circular opening therethrough having a thickened rounded mouth upon its upper side; of a pole or stock having a jointed hand-grip at one end and a spherical knob at the other end adapted to rest in the mouth of said opening, and have a universal movement therein, and an adjustable weight mounted upon said pole or stock, substantially as and for the purposes described.

605,748. GATE. THEODORE SAWYER, Towanda, Ill. Filed Jan. 14, 1898. Serial No. 666,642. (No model.)



Claim.—1. A gate, having a spring closed latch mounted to slide longitudinally upon the gate, an eye attached to said latch, a bent lever composed of a vertical and a horizontal member pivoted by the lower end of the vertical member below said latch, the vertical member of said lever passing through the eye, a yoke fixed to the frame and embracing the upper horizontal member to form a guide therefor, a shaft mounted horizontally above the gate and extending at right angles to the gate when in its closed position, a crank-arm upon the shaft near the gate-pivot, and a link connecting the said crank-arm with the upper end of the latch-operating lever on the gate, substantially as described.

2. A gate, having a spring-closed latch mounted to slide longitudinally upon the gate, an eye attached to said latch, a bent lever pivoted by its lower end below said latch, the vertical member of said lever passing through the eye, a yoke fixed to the frame and embracing the upper horizontal member to form a guide therefor, a shaft mounted horizontally above the gate and extending at right angles to the gate when in its closed position, a crank-arm upon the shaft near the gate pivot, a link connecting the said crank-arm with the upper end of the latch-operating lever on the gate, a crank-arm mounted loosely on the shaft outside the fixed crank-arm, and a link connecting the end of said crank-arm with the gate outside the connection of the other link thereto, the same acting as a guard for the first crank-arm and link, substantially as described.

3. A gate having a spring-closed latch mounted to slide longitudinally upon the gate, an eye attached to said latch, a bent lever composed of a vertical and a horizontal member pivoted by the lower end of the vertical member below said latch, the vertical member of said lever passing through the eye, a yoke fixed to the frame and embracing the upper horizontal member to form a guide therefor, a shaft mounted horizontally above the gate and extending at right angles to the gate when in its closed position, operating-arms pivoted to the ends of said shaft so as to swing in a plane which includes the shaft, a crank-arm upon the shaft near the gate-pivot, and a link connecting said crank-arm with the upper end of the bent latch-operating lever on the gate, substantially as described

605,749. COIN-OPERATED LOCK FOR VEHICLE-WHEELS. REICH SCHNIPP and ADOLPH F. SCHNEIDER, New York, N. Y. Filed Apr. 12, 1897. Serial No. 631,719. (No model.)

Claim.—1. A lock for a bicycle-wheel, comprising a socket, a gate therefor, a bolt for engagement with said gate, and a coin-controlled means for locking the key of the lock, substantially as described.

2. A casing, a keeper adapted to receive a vehicle-wheel, a bolt adapted for engagement with the keeper and carried by the casing, and a coin-controlled lock-lever adapted to engage the key and prevent its turning or withdrawal, substantially as described.

3. A casing, a keeper for a vehicle-wheel, provided with a gate, a lock carried by the casing, the bolt of which is adapted for engagement with the gate of the wheel-keeper, a coin-receptacle, a lock-lever preventing the withdrawal of the key from the lock, said lever being adapted to receive the coin from the said receptacle, and a plunger arranged to move the coin in a direction to raise the lock-lever from the key, as and for the purpose set forth.

4. The combination, with a casing, a keeper for a vehicle-wheel, and a gate for the said keeper, of a lock contained in the casing, the bolt whereof is adapted for engagement with the said gate, a lock-lever normally engaging with the key of the lock and preventing its movement, and a plunger operating upon the said lock-lever through the medium of a coin, to raise the lever from the path of the key, as and for the purpose set forth.

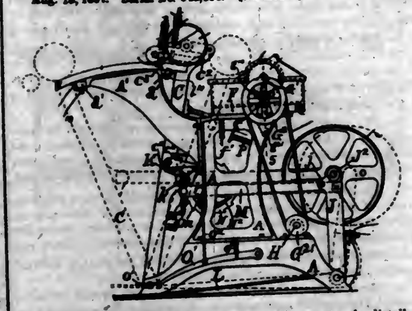
5. The combination, with a casing, a keeper adapted to receive the tire and rim of a bicycle-wheel, a gate for the said keeper, and a key-operated lock located in the casing, the bolt whereof is adapted for engagement with the gate of said keeper, of a coin-chute, a lock-lever pivoted below the coin-chute, having a recess to receive a coin and a head which is normally in the path of the key of the lock, a weighted arm arranged for engagement with one face of the said coin, and a plunger adapted to act upon a coin when seated upon the lock-lever, as and for the purpose set forth.

6. The combination, with a casing, a keeper adapted to receive the rim and tire of a bicycle or other wheel, a gate provided for the keeper, and a key-operated lock located in the casing, the bolt whereof is adapted for engagement with said gate, of a lock-lever having a portion thereof normally held in the path of the key, preventing its withdrawal and preventing its turning, said lock-lever being provided with a recess adapted to receive the coin, and a vertical wall at one side of the recess, a gravity-arm, the foot portion whereof is arranged for engagement with the coin carried by the lock-lever, engaging said coin at the face opposite that in contact with the said wall, and a plunger arranged to carry the coin in a direction for lifting the lock-lever out of the path of the key, substantially as shown and described.

7. A lock for bicycle-wheels a lock lever for the key, which lever in its normal position prevents the key from being withdrawn or turned, said lever being operated by a coin acting directly upon it for carrying it out of the path of the key, and a plunger operating on the coin, as and for the purpose specified.

8. The combination with a casing, and a lock therein, of a lever arranged in the casing and adapted to engage the key to prevent its movement or withdrawal, said lever being operated by a coin acting directly upon it for carrying it out of the path of the key, substantially as described.

9. The combination with a casing, and a lock therein, of a pivoted and spring-pressed lever adapted to engage the key of the lock and to be engaged by a coin, a coin-chute above the said lever, and a plunger in said coin-chute, substantially as described.



10. The combination with a casing and a lock therein, of a coin-chute having one wall slotted, a weighted arm pivoted in the slot of the coin chute, a plunger in the said chute and a pivoted and spring-pressed lever below the coin-chute and adapted to receive a coin therefrom, said lever being adapted to engage the key of the lock and prevent its movement or withdrawal, substantially as herein shown and described.

605,750. TILED ROOF. CHRISTIAN W. SIMON, Aalborg, Denmark. Filed Dec. 10, 1896. Serial No. 615,289. (No model.) Patented in Germany Apr. 25, 1895, No. 90,730.

Claim.—Tiles for roofing, made of baked and hardened plastic material and with recesses inclined downward toward their sides and adapted to receive tightly the bent-over flanges of metal strips, combined with metal strips whose bent edges or flanges are secured in such slits, and which strips tend to draw the tiles together, and also cover the joints.

605,751. STARCHING-MACHINE. ARTHUR B. SELDEN, Rochester, N. Y., assignor to Francis S. Macomber, trustee, same place. Filed Aug. 13, 1897. Serial No. 648,150. (No model.)

Claim.—1. The combination of a table, a starch-distributer, means for supplying starch to said distributer, devices for moving said distributer to and fro over said table, and mechanism for moving said distributer from said table and to and from said means for supplying starch.

2. The combination of a table, a starch-distributer, means for supplying starch to said distributer, devices for moving said distributer to and fro over said table, mechanism for moving said distributer to and from said means for supplying starch, and locking mechanism for retaining said devices for moving said distributer to and fro over said table in operating position.

3. The combination of a table, a starch-distributer, means for supplying starch to said distributer, devices for moving said distributer to and fro over said table, mechanism for moving said distributer to and from said means for supplying starch, locking mechanism for retaining said devices for moving said distributer to and fro over said table in operating position, and automatic releasing mechanism for releasing said locking mechanism.

4. The combination of a table, a starch-distributer, means for supplying starch to said distributer, devices for moving said distributer to and fro over said table, mechanism for moving said distributer to and from said means for supplying starch, locking mechanism for retaining said devices for moving said distributer to and fro over said table in operating position, and automatic releasing mechanism comprising a counting apparatus for releasing said locking mechanism after a predetermined number of movements of said devices.

5. The combination of a table, a starch-distributer, means for moving said distributer to and fro over said table, mechanism for producing an extra movement of said distributer in one direction for moving the same off said table, and means for supplying starch to said distributer at the end of said extra movement.

6. The combination of a table, a starch-distributer, means for moving said distributer to and fro over said table, mechanism for producing an extra movement of said distributer in one direction for moving the same off said table, means for supplying starch to said distributer at the end of said extra movement, and locking mechanism for retaining said means for moving said distributer to and fro over said table in operating position.

7. The combination of a table, a starch-distributer, means for moving said distributer to and fro over said table, mechanism for producing an extra movement of said distributer in one direction for moving the same off said table, means for supplying starch to said distributer at the end of said extra movement, locking mechanism for retaining said means for moving said distributer to and fro over said table in operating position, and automatic releasing mechanism for releasing said locking mechanism.

8. The combination of a table, a starch-distributer, means for moving said distributer to and fro over said table, mechanism for producing an extra movement of said distributer in one direction for moving the same off said table, means for supplying starch to said distributer at the end of said extra movement, locking mechanism for retaining said means for moving said distributer to and fro over

said table in operating position, and automatic releasing mechanism involving a counting device for releasing said locking mechanism after a predetermined number of operations of said means for moving said distributer.

9. The combination of a table, a starch-distributer, means for moving said distributer to and fro over said table, a starch-box, a starch-feeding mechanism for delivering starch from said box to said distributer, and mechanism for moving said distributer to and from said table and to and from said starch-feeding mechanism.

10. The combination of a table, a starch-distributer, means for moving said distributer to and fro over said table, a starch-box, a starch-feeding mechanism for delivering starch from said box to said distributer, mechanism for moving said distributer to and from said table and to and from said starch-feeding mechanism, and locking mechanism for retaining said devices for moving said distributer to and fro over said table in operating position.

11. The combination of a table, a starcher-roll, devices for moving said roll to and fro over said table, means for supplying starch to said roll, and mechanism for moving said roll from said table and to and from said means for supplying starch.

12. The combination of a table, a starcher-roll, devices for moving said roll to and fro over said table, mechanism for producing an extra movement of said roll in one direction off said table, and means for supplying starch to said roll at the end of said extra movement.

13. The combination of a table, a starcher-roll, devices for moving said roll to and fro over said table, mechanism for producing an extra movement of said roll in one direction off said table, means for supplying starch to said roll at the end of said extra movement, and locking mechanism for retaining the said devices for moving said roll to and fro over said table in operating position.

14. The combination of a table, a starcher-roll, devices for moving said roll to and fro over said table, mechanism for producing an extra movement of said roll in one direction off said table, and means for supplying starch to said roll at the end of said extra movement, locking mechanism for retaining said devices for moving said roll to and fro over said table in operating position, and automatic releasing mechanism for releasing said locking mechanism.

15. The combination of a table, a starch-distributer, a movable frame for carrying said starch-distributer to and fro over said table, a driving mechanism, connections between said driving mechanism and said movable frame, a locking mechanism for retaining said connections in operating position, and a releasing mechanism actuated by said movable frame.

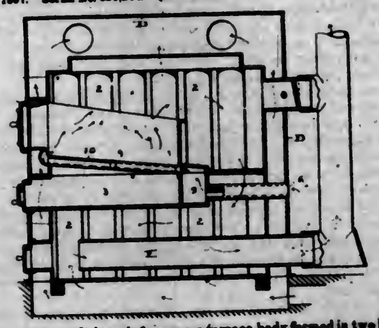
16. The combination of a table, a starch-distributer, a movable frame for moving said distributer to and fro over said table, a driving mechanism, connections between said driving mechanism and said frame, locking mechanism for retaining said connections in operating position, and a cam device actuated by said connections for releasing said locking mechanism.

17. The combination of a table, a starch-distributer, a movable frame for moving said distributer to and fro over said table, a driving mechanism, connections between said driving mechanism and said frame, locking mechanism for retaining said connections in operating position, and a wheel actuated by movement of said connections and provided with a cam device for releasing said locking mechanism.

18. The combination of a table, a starch-distributer, a movable frame for moving said distributer to and fro over said table, a driving mechanism, connections between said driving mechanism and said frame, locking mechanism for retaining said connections in operating position, a ratchet-wheel having a cam for releasing said locking mechanism, a dog carried by said frame for moving said wheel step by step to release said locking mechanism after a predetermined number of movements of said frame.

19. The combination of a table, a starch distributer, a movable frame for moving said distributer to and fro over said table, a driving mechanism, connections between said driving mechanism and said frame, locking mechanism for retaining said connections in operating position, a ratchet-wheel provided with adjustable stop mechanism for determining the point whereat said wheel may commence to turn, a stationary cam device upon said wheel for releasing said locking mechanism, and a dog carried by said frame for moving said ratchet-wheel step by step to release said locking mechanism after a predetermined number of movements of said frame.

20. The combination of a table, a starch-distributer, a movable frame for moving said distributer to and fro over said table, a driving mechanism, connections between said driving mechanism and said frame, locking mechanism for retaining said connections in operating position, a wheel provided with adjustable stop mechanism for determining the point whereat said wheel may commence to turn, a stationary cam device upon said wheel for releasing said locking mechanism, means normally tending to move said wheel in one direction, and mechanism actuated by said connections for turning said wheel step by step in the other direction.



21. The combination of a bed, a starcher-roll frame oscillating along one side of said bed, a starcher-roll carried by said frame and projecting over said bed, and pivoted means for said bed adapted to permit said bed to oscillate transversely with reference to the oscillations of the said frame, and spring for retaining said bed in normal position.

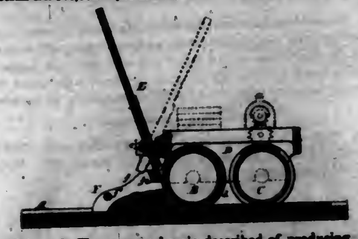
605,752. HANDLE-BAR FOR CYCLES. HARVEY G. SHEPARD, New Haven, Conn., assignor to H. G. Shepard & Sons, same place. Filed Jan. 18, 1898. Serial No. 673,955. (No model.)

Claim.—The combination in a handle-bar bearing, with a rigid lower member formed with a horizontally-arranged, semicircular or substantially semicircular groove, and with a long, upwardly-projecting integral knife-like rib or tooth arranged longitudinally in the center of the bottom of the said groove, of a removable upper member or cap having a semicircular or substantially semicircular groove formed in it, and provided with a long longitudinally-arranged, downwardly-projecting integral knife-like rib or tooth located in the center of its bottom and therefore opposite the rib or tooth aforesaid, and means for securing the said upper member to the said lower member, the ends of the said member and cap being beveled to avoid biting the bar at the points where the same emerges from the bearing, substantially as described.

605,758. FURNACE. ROBERT L. SHARP, Cleveland, Ohio, assignor to the Cartland Foundry Company, same place. Filed June 3, 1897. Serial No. 639,264. (No model.)

Claim.—1. In hot-air furnaces, a furnace-body formed in two horizontal sections, fresh-air tubes in each section extending the full depth of the sections and matching to make continuous passages, a horizontal diaphragm about said flues to cut off downdraft about them a downdraft-opening in the rear of the furnace and no exit for the products of combustion leading from the bottom section of the furnace near its front, whereby the outgoing heat reaches the fresh-air flues in the bottom of the furnace and is absorbed, substantially as set forth.

2. The furnace-casing consisting of two horizontal sections, fresh-air tubes extending through both sections in series along both sides thereof and a horizontal diaphragm between said sections closing the downdraft about said tubes and leaving a draft-opening for the products of combustion from the upper to the lower section, a fire-box in said upper section having side walls to protect the fresh-air flues, and an ash-pit in the lower section, and an exit for the products of combustion having its entrance in the end of the said lower section opposite said downdraft, whereby the fresh-air tubes in the lower section are heated and the heat is taken up, substantially as set forth.



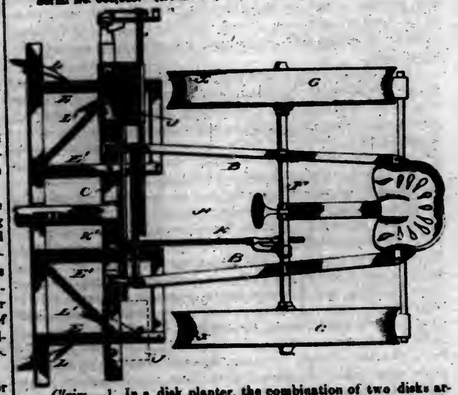
3. In air-heating furnaces, a furnace-body having fresh-air flues extending vertically through the same and open at both ends, a fire-chamber between said flues and apart therefrom and a downdraft at the rear of the furnace whereby the flame is kept from said tubes, and tubular grate-bars at the bottom of said chamber constructed to discharge into said heat-chamber at their front ends over the fuel, in combination with air-supply connections with the rear ends of said grate-bars traversing the said downdraft from the fire-chamber, whereby the air entering the grate-bars is heated and fed over the fuel, substantially as described.

4. In air-heating furnaces, the body of the furnace having fresh-air flues through from bottom to top and a horizontal division between said flues midway their elevation to cut off downdraft about said tubes and having a downdraft-passage centrally at its rear, and an exit-flue in its bottom having its mouth at the front of the furnace, in combination with air-supplying grate-bars constructed and arranged to discharge air over the fuel in the furnace, and air-supply connections for said grate-bars directly exposed to the outgoing heat from the furnace, substantially as described.

5. In air-heating furnaces, the body consisting of two separate sections placed one on top of the other and having air-flues passing vertically through them, said sections closed horizontally about said tubes midway their elevation, the exit-flue in the lower section having its mouth in the front of the furnace, the fire-chamber in the upper section and the hollow grate-bars at the bottom of said chamber constructed to carry finely-divided coal and to discharge air over the coal at their front ends, and a draft-passage for the products of combustion with the furnace and air-supply connections for said hollow grate-bars exposed to said draft-passage, whereby the air entering the grate-bars is heated, substantially as described.

6. In heating-furnaces, a furnace-body having upper and lower horizontal chambers and a down-passage at its rear from one chamber to the other, a fire-box in the upper chamber and an exit-flue in the lower chamber and fresh-air flues extending along its sides through both chambers, in combination with a grate for said fire-box consisting of hollow bars having their front ends turned upward and inward to discharge into the fire at their front and air-supply connections for said grate-bars at the rear ends, traversing the said down-passage, whereby the air entering the grate-bars is heated, substantially as described.

605,754. PROCESS OF AND MACHINE FOR EMBEDDING WIRE IN GLASS. FRANK SHUMAN, Philadelphia, Pa. Filed Jan. 20, 1898. Serial No. 678,128. (No model.)



Claim.—1. The process herein described of producing what is known as "wire-glass," said process consisting in simultaneously and coincidently forcing the wire into the glass until it reaches the position in which it is to remain therein and rolling the glass into a sheet, and then covering the embedded wire by rolling down that surface of the glass through which the wire was forced.

2. In a wire-glass-making machine, the combination of a table, a roller mounted to travel at such a fixed distance above the same that the wire to be forced into the glass will be forced to the place where it is to remain therein, said roller having spaced ribs on its periphery, and means for feeding a sheet of wire down in front of the roller and to be forced thereby into a mass of glass placed on the table in front of the same, whereby the wire will be pressed into the glass until it reaches the position in which it is to remain therein, and the glass will, at the same time and place, be rolled into a sheet of uniform thickness, substantially as described.

3. In a wire-glass-making machine, the combination of a table, a roller mounted to travel at such a fixed distance above the same that the wire to be forced into the glass will be forced to the place where it is to remain therein, said roller having spaced ribs on its periphery, means for feeding a sheet of wire down in front of the roller, and to be forced thereby into a mass of glass placed on the table in front of the same, and a roll following the ribbed roll, and having its surface closer to the table than the bases of the ribs on said ribbed roll, whereby the wire is pressed into the glass until it reaches the position in which it is to remain therein, the glass is at the same time and place rolled into a sheet of uniform thickness, and the projecting ribs in the upper surface of the glass are finally rolled down, so as to cover and inclose the embedded wire, substantially as described.

605,755. DISK PLANTER. MATTHEW P. SIMPSON, ELI P. WILLIAMS, and JAMES M. SIMPSON, McPherson, Kans. Filed Jan. 14, 1898. Serial No. 666,865. (No model.)

Claim.—1. In a disk planter, the combination of two disks arranged in different longitudinal planes one behind the other, said front disk being adjustable laterally toward and from the rear disk, and a seed-delivery device or spout arranged to discharge behind or on the convex side of said rear disk, substantially as described.

2. In a disk planter, the combination of two disks arranged in different longitudinal planes one behind the other, and adjustable laterally toward or from each other, a seed-delivery device or spout arranged to discharge behind or on the convex side of said rear disk, and a presser-wheel arranged to follow directly behind the disks, substantially as described.

3. In a disk planter, the combination, with the front and rear disks arranged in different longitudinal planes, of a seed-delivery device or spout arranged behind or on the convex side of said rear disk, whereby the furrow formed by the front disk will be covered by the earth thrown back by the rear disk and the seed deposited in the furrow formed in a loose ridge of earth by said rear disk, substantially as described.

605,756. OIL WELL-TUBING ATTACHMENT. ANDY C. SMITH, Sigel, Pa. Filed Dec. 17, 1897. Serial No. 662,320. (No model.)

Claim.—1. The improvement in well-tubing herein described comprising the packer, having the left-hand thread at its upper end.

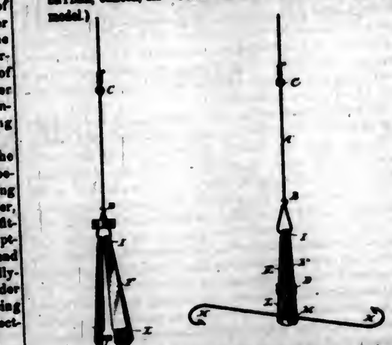
the tube fixed to and projected upward from said packer and provided at its upper end with a downwardly-facing shoulder, such tube being provided with an opening and the cover-sleeve sliding on said tube provided at its lower end with a left-hand thread to engage that of the packer and having at such end an internal upwardly-facing shoulder to engage that at the upper end of the tube, substantially as set forth.

2. In an apparatus substantially as described the combination of the packer having the left-hand thread at its upper end, the packer tube-section connected with and extended from the upper end of the packer and having an opening, the main tube-section and the cover-sleeve adapted at its lower end to engage the left-hand threads of the packer and also arranged to engage the upper end of the packer tube-section when the cover-sleeve is lifted, the cover-sleeve being independent of the packer whereby it may be moved without affecting the packing operation, substantially as described.

3. The improved apparatus herein described consisting of the packer having the left-hand thread at its upper end, the packer tube-section extended upward from the packer and having an opening and provided at its upper end with a downwardly-facing shoulder, the main tubing, and the cover-sleeve connected therewith and fitting down over the packer tube-section, such cover-sleeve being adapted at its lower end to engage the left-hand thread at the upper end of the packer and also having at its lower end an internal upwardly-facing shoulder whereby to engage the downwardly-facing shoulder at the upper end of the packer tube-section, the cover-sleeve being independent of the packer whereby it may be moved without affecting the packing operation, substantially as shown and described.

4. The combination of the packer, the tube projected up from the packer, and provided with longitudinal slots, and having the shoulder at its upper end, the left-hand thread at the upper end of the packer, and the cover-sleeve independent of the packer and movable over the tube above said packer, such cover-sleeve being arranged at its lower end to jar upon the packer, provided internally near such end with threads to fit those at the top of the packer and having near such end an internally upwardly-facing shoulder to bind beneath that at the top of the tube substantially as set forth.

605,757. JOURNAL-BOX. WALTER W. SMITH, Detroit, Mich. Filed Feb. 5, 1898. Serial No. 669,265. (No model.)

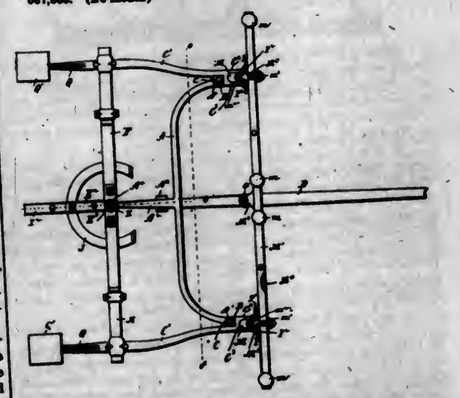


Claim.—1. In a journal-box, the combination with a box forming a portion of the bearing and provided in the bottom thereof with an opening, of a cellar fitted in said opening and secured to the box and forming the complemental bearing, said cellar being formed with imperforate bottom, side and end walls and an open top, perforated plates secured to the side walls of the cellar and forming therewith oil-reservoirs, one of which is adapted to be replenished with oil through an opening in the cellar, packing in the cellar, a follower-plate adapted to press the packing against the journal, and means independent of the bottom of the cellar and interposed between the same and follower-plate for conveying oil from one reservoir to the other, substantially as described.

2. In a journal-box, the combination of a cellar comprising imperforate bottom, side and end walls, and an open top, said end walls serving as a portion of the bearing for the journal and one of the walls being provided with an oil-inlet opening, detachable perforated plates secured to the side walls thereof and forming therewith two oil-reservoirs, one of which is in communication with said inlet-opening, a packing of absorbent material in the cellar, a spring-pressed follower-plate adapted to hold the same in engagement with the journal, and a pipe arranged below the follower-plate and communicating between the oil-reservoirs, substantially as described.

3. In a journal-box, the combination of the cellar, perforated plates secured therein to the side walls thereof and flaring outwardly therefrom to form oil-reservoirs, an inlet for one of said reservoirs, a pipe connecting said reservoirs, a packing of absorbent material positioned in the compartment formed between the oil-reservoirs, guide-posts in the cellar, a plate movable thereon, and springs engaging said plate and holding the packing pressed against the journal, substantially as described.

605,758. DEVICE FOR HOLDING FISH-HOOKS. JOHN H. SNYDER, Canton, Ill. Filed June 19, 1897. Serial No. 641,294. (No model.)



Claim.—1. A fish-hook holder comprising means for clamping a fish-hook rigidly at an angle thereto and having an engaging portion adapted to project through the eye of the hook to hold the same against separation from the holder, substantially as described.

2. A combination fish-hook holder and sinker comprising means for holding the shank of a hook rigidly at any angle with respect thereto, substantially as described.

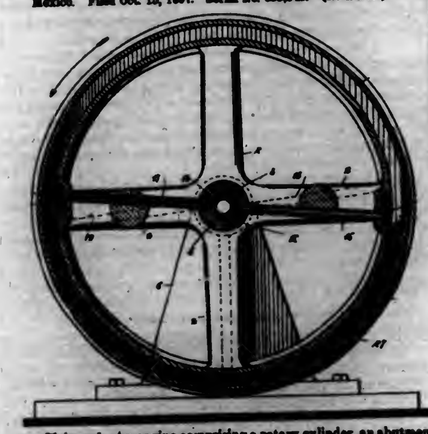
3. A fish-hook holder comprising two half-round sections one of said sections being provided with a pin and the other with a recess for reception of the hook and an opening for reception of said pin and means for securing the sections together, substantially as described.

4. The combination with a fish-hook, of a holder therefor capable of sustaining itself in a vertical position when submerged in water and adapted for attachment to the end of a line or snell, said holder also comprising means for securing the hook rigidly with the shank thereof at an angle to the axis of the holder, substantially as described.

605,759. CONVERTIBLE RUNNING-GEAR FOR VEHICLES. ANTHONY V. SPARS, New Haven, Conn. Filed Jan. 26, 1898. Serial No. 667,895. (No model.)

Claim.—1. In a convertible running-gear for vehicles, the combination with two fore hounds extending forward from the fore axle, and adapted to have a draw-bar or shafts interchangeably connected with their forward ends, of a yoke permanently connected with the hounds, and formed with a rearwardly-extending combined supporting and draft arm connected at its rear end with the running-gear at a point above the head-block thereof.

2. In a convertible running-gear for vehicles, the combination with two hounds extending forward from the fore axle and adapted at their forward ends to have shafts or a draw-bar interchangeably connected with them, and a yoke connected with the said hounds, and also connected with a stud located above and in line with the king-bolt of the gear.



3. In a convertible perch running-gear for vehicles, the combination with the head-block thereof, of a spring mounted thereupon, a spring-plate attached at its rear end to the perch, and at its forward end resting upon the said spring, and secured to the said head-block, and provided with an upwardly-extending stud and with a recess located below the same, a king-bolt extending upward through the said head-block and into the said recess which receives the nut applied to the upper end of the said king-bolt which is located below and in line with said stud, a yoke adapted at its rear end to be directly connected with the said stud, and fore hounds having the forward ends of the yoke connected with them, and being themselves adapted to interchangeably receive shafts or a draw-bar.

4. In a convertible running-gear for vehicles, the combination with the fore axle, the head-block and the king-bolt thereof, of fore hounds connected at their rear ends with the fore axle, and having their forward ends adapted for interchangeable connection with them, of shafts or a draw-bar, and a yoke having its members bent downwardly and forwardly, and connected at their ends with the said hounds, the said yoke being provided with a rearwardly-extending, centrally-arranged arm adapted to be connected with the gear at a point above the head-block and over the king-bolt.

5. In a convertible running-gear for vehicles, the combination with the head-block thereof, of a spring-plate connected with the said head-block, provided with an upwardly-projecting stud, and formed with a recess located below the same, a yoke having a rearwardly-extending arm adapted to be connected directly with the said head, and with two forwardly-extending members, and fore hounds having the forwardly-extending members of the yoke connected with them, and connected at their rear ends with the fore axle of the gear.

6. In a running-gear for vehicles, the combination with a plate adapted to be attached at its rear end to the perch and at its forward end to rest upon the head-block spring, and provided with an upwardly-extending stud or auxiliary king-bolt and formed with a recess located below the said stud and receiving the upper end of the king-bolt and the nut applied thereto, the said stud or auxiliary king-bolt being adapted to take a portion of the draft or strain imposed upon the running-gear.

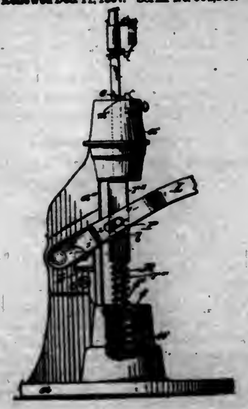
605,760. ROTARY ENGINE. ALEJANDRO STEPHENS, Guadalajara, Mexico. Filed Oct. 15, 1897. Serial No. 655,245. (No model.)

Claim.—1. An engine comprising a rotary cylinder, an abutment therein, a controlling-valve, a gear-wheel secured to the controlling-valve, a piston-valve mounted to swing in the cylinder and means for imparting movement to the said gear-wheel from the said piston-valve to actuate the controlling-valve, substantially as specified.

2. A rotary engine comprising a rotary cylinder, a segmental abutment loosely mounted in the cylinder, the said abutment being formed with independent sections at its steam-pressure end, the said sections having their ends oppositely inclined and the end of one section bearing upon the end of another section, substantially as specified.

3. An engine comprising a rotary cylinder, means for controlling the inlet and outlet of steam, and a segmental abutment in the cylinder having short bearing portions for engaging the opposite walls of the cylinder, the said abutment being formed with sections at its steam-pressure end, the said sections having their ends oppositely inclined and the end of one section bearing upon the end of another section, substantially as specified.

4. A rotary engine comprising a wheel-like cylinder, a segmental abutment in the cylinder having short bearing portions for engaging the opposite walls of the cylinder, the said abutments being formed with sections at its steam-pressure end, the said sections having their ends oppositely inclined and the end of one section bearing upon the end of another section, piston-valves mounted to swing in the cylinder, steam-inlet pipes extending through the inner wall of the cylinder in line with the piston-valves, a controlling-valve and means for giving a rocking motion to the said controlling-valve substantially as specified.



5. An engine comprising a rotary cylinder, a segmental abutment loosely mounted in the cylinder and formed with sections at its steam-pressure end, the said sections having their ends oppositely inclined and the end of one section bearing upon the end of another section, a tubular hub in which the cylinder is mounted, said tubular hub having steam-chambers formed in its inner walls, said chambers having communication with the interior of the cylinder, piston-valves in the cylinder adapted to engage over the inner ends of said communications, a tubular valve in the hub portion having steam inlet and exhaust ports, and means whereby the movement of the piston-valves imparts a rocking movement to the said tubular valve, substantially as specified.

6. An engine, comprising a rotary cylinder, a segmental abutment loosely mounted in the cylinder, oppositely-arranged piston-valves movable in the cylinder, steam-inlet pipes, a controlling-valve for the steam, a gear-wheel rigidly secured to the said controlling-valve, and gear-wheels meshing with the gear secured to the controlling-valve and actuated from the said piston-valves, substantially as specified.

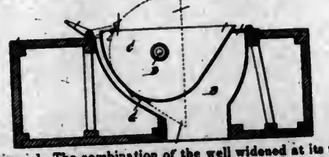
7. A rotary engine, comprising a rotating cylinder, an abutment therein, a controlling-valve engaged in the hollow hub of the cylinder, a gear-wheel attached to said valve, gear-wheels mounted on studs carried by the cylinder and engaging at opposite sides with the first-named gear-wheel, segmental racks on said outer gear-wheel, piston-valves mounted to swing in the cylinder, arms extended from the shafts of said piston-valves, fingers extended at substantially right angles to said arms, and teeth on said fingers for engaging the segment-racks on the wheels, substantially as specified.

8. An engine comprising a rotary cylinder, an abutment therein, piston-valves mounted to swing in the cylinder, a tubular hub on which the cylinder is mounted, a tubular valve engaging the opening in the hub, a partition intermediate of the ends of the tubular valve, the said valve being provided with a steam-inlet port at one side of the partition and an exhaust-port at the other side of the partition, pipes providing communication between said ports and the interior of the cylinder, a steam-pipe connecting with the said valve a spring for holding the valve yieldingly in its seat, a tension-adjusting device for the steam-pipe, and a connection between the said piston-valves and the said tubular valve, whereby the swinging of the piston-valves imparts a rocking motion to the said tubular valve, substantially as specified.

605,761. TOOL FOR CUTTING AND BINDING METALLIC STRIPS. THEODORE L. SEWARD, Brooklyn, N. Y., assignor, by mesne assignments, to the Venetian Iron Company, of New Jersey. Filed Jan. 14, 1896. Renewed Dec. 11, 1897. Serial No. 661,580. (No model.)

Claim.—1. In a binding-tool the combination with a bar, of two jaws provided with angular pockets adjoining said bar, and means for bringing the jaws toward each other.

2. The combination with a bar carrying a jaw having an angular pocket adjoining said bar, of another jaw also having an angular pocket adjoining said bar and mounted on a guide-head through which said bar passes.



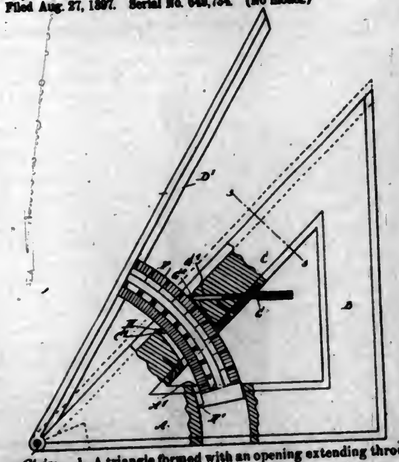
3. The combination with a bar and means for moving the same, of two jaws each provided with an angular pocket adjoining said bar, one detachably mounted on said bar and the other similarly mounted on the guide for said bar.

4. In a binding-tool the combination with a bar of a jaw provided with an angular pocket adjoining said bar and means for detachably securing the jaw to said bar.

5. In a binding-tool the combination with a bar of two jaws each provided with an angular pocket adjoining said bar, means for actuating said bar and means for normally keeping the jaws apart when not in use.

6. The combination with a standard of a bar, two jaws provided with pockets adjoining said bar, a lever provided with a knife-edge and adapted to actuate said bar, and a corresponding knife-edge mounted on the standard.

605,762. DUMPING-SCOW. MATT STICKNEY, Bradford, Mass. Filed Nov. 20, 1897. Serial No. 659,262. (No model.)



Claim.—1. The combination of the well widened at its top, and the dumping-receptacle mounted to turn in said widened portion and so arranged that in the discharging position the outlet of the receptacle is within the well and substantially at the lower end of the widened portion thereof.

2. A dumping-scow provided with a well, open at the bottom, a receptacle pivoted at its ends in the hold, and having its discharge side arranged to overbalance the opposite side, so that upon releasing the receptacle from a normal position, it will turn automatically on its pivots into a dumping position and discharge the load, and means, substantially as described, for locking the receptacle in a dumping position, as set forth.

3. The combination of the support, the dumping-receptacle movably mounted thereon and constructed with a tendency to assume the receiving position when empty and to rock into the discharging position when filled, and means for locking the receptacle in the discharging position.

605,763. TRIANGLE. BENJAMIN W. TRUNK, St. Joseph, Mo. Filed Aug. 27, 1897. Serial No. 649,734. (No model.)

Claim.—1. A triangle formed with an opening extending through its hypotenusal side from the outer to the inner edge of the same and into an adjacent side, an edge or section hinged to said triangle at one of the acute angles of the same, a pin in the opening of the hypotenusal side, a protractor carried by said hinged edge or section and fitted to slide in said openings, said protractor being formed at its free end with a lug which engages with said pin to limit its outward movement, a spring in the opening of the hypotenusal side and bearing against an edge of said protractor, and a thumb-screw in said latter side and by which the spring is brought to press upon said protractor to hold the same in adjusted position as and for the purpose set forth.

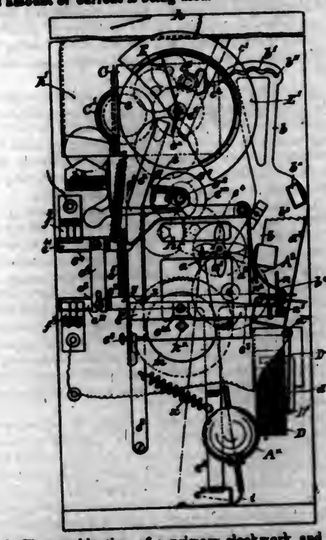
2. A triangle formed along the edge of one side with a longitudinal recess extending from end to end thereof and an opening extending through said recessed side and into an adjacent side, a section or edge hinged to said triangle and formed with a tongue by which it fits into the said recess, a pin in the opening of the recessed side, a protractor carried by said hinged edge or section and fitted to slide in the said openings, said protractor being formed at its free end with a lug adapted to engage said pin to limit its outward movement, a spring in the opening of the recessed side and bearing against the edge of said protractor, and a thumb-screw in said latter side and by which the spring is brought to press upon said protractor to hold the same in adjusted position, as and for the purpose described.

605,764. VIOLIN OR MANDOLIN CITHERN. ALEXANDER WASGINDT, Jersey City, N. J., assignor to Elizabeth Hahner, Carl Franck, and Jacob Veith, New York, N. Y. Filed Oct. 22, 1897. Serial No. 656,052. (No model.)

Claim.—1. A stringed musical instrument, provided with a bow-guide extending transversely of the strings on one side thereof, movable dampers normally engaging the strings on the other side, and means for removing the dampers from the strings, substantially as described.

2. A stringed musical instrument, provided with spaced bow-guides extending transversely of the strings on one side thereof, movable dampers arranged on the other side of the strings and having spaced damping-cushions normally engaging the strings at points substantially registering with the bow-guides, and means for removing the dampers from the strings, substantially as described.

3. A stringed musical instrument, provided with a bridge normally engaging the strings, another bridge normally out of engagement therewith, dampers normally engaging the strings, pressers arranged between the two bridges and each adapted to engage a string to force it against the last-named bridge, and an operative connection between the presser and the corresponding damper whereby the latter will be removed from the string before the presser engages the same, substantially as described.



4. A stringed musical instrument, provided with a bridge normally engaging the strings, another bridge normally out of engagement with the strings, dampers normally engaging the strings, spring-levers carrying said dampers, and pressers carried by said levers and each adapted to engage a string to force it against the last-named bridge, substantially as described.

5. A bow for musical instruments, consisting of a toothed strip of soft rubber and a back or body carrying said strip.

605,765. APPARATUS FOR SUPPLYING OR MEASURING CURRENTS OF ELECTRICITY. WILLIAM D WATSON and THOMAS HUMPHREYS, Rochdale, England; said Humphreys assignor to said Watson. Filed Dec. 23, 1897. Serial No. 663,972. (No model.)

Claim.—1. Mechanism for supplying and measuring electricity, consisting of primary clockwork, auxiliary clockwork, a governing-lever actuated by said primary clockwork and controlling the escapement of the auxiliary clockwork, in combination with a cut-out device actuated by the auxiliary clockwork and a device (controlled by the strength of the current used) whereby the governing-lever remains inactive when no current is being used and allows the aforesaid escapement to work quickly or slowly according as a greater or less amount of current is being used.

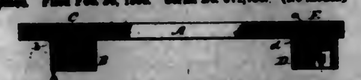
2. Mechanism for supplying and measuring electricity consisting of primary clockwork, auxiliary clockwork, a governing-lever actuated by said primary clockwork and controlling the escapement of the auxiliary clockwork, in combination with a cut-out device and an indicator actuated by the auxiliary clockwork and a device controlled by the strength of the current used, whereby the governing-lever remains inactive when no current is being used, and allows the aforesaid escapement to work quickly or slowly according as a greater or less amount of current is being used.

3. The combination of a primary clockwork and an ampere-meter, with a governing-lever controlled by the said ampere-meter, the said primary clockwork adapted to actuate the said lever subject to the control thereof by the ampere-meter, and a secondary clockwork controlled by the said lever.

4. The combination of a primary clockwork, a cam actuated thereby, and an ampere-meter, with an auxiliary clockwork, a lever governing the same, the said lever adapted to engage with more or less of the surface of said cam according to the control of the said ampere-meter, substantially as and for the purpose set forth.

5. The combination of the clockwork A and C and their adjuncts with the setting-disk c, arbor c', projection c^x, handle g', sector g and shaft g^2.

6. The combination of the clockwork A and C and their adjuncts with an electric switch, the setting-disk c projection c^x, arbor c' and lever c^3 for tripping the electric switch to shut off the current.

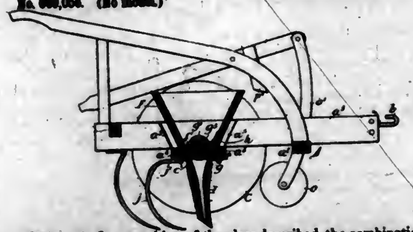


7. The combination of the clockwork A and C and their adjuncts, with the setting-lever c^3, plates f', f^2, and switch-levers c^4, c^5 linked together and connecting the plates f' f^2 to complete the electric circuit.

8. The combination of the clockwork A and C and their adjuncts, with mechanism for cutting off the current-supply and means actuated by the key of the clockwork A when applied thereto for working the cut-out, substantially as hereinbefore described.

9. The combination of the clockwork A and C and their adjuncts, with mechanism for cutting off the current-supply and means for simultaneously stopping the clockwork A, substantially as hereinbefore described.

10. The combination of a primary clockwork, an ampere-meter, and a governing-lever controlled by the ampere-meter and actuated by the primary clockwork subject to the control of the said ampere-meter, the said lever being provided with a cam, with an auxiliary clockwork, the escapement-lever of which is adapted to engage with and be operated by more or less of the said cam according to the control of the said ampere meter over the said lever, substantially as and for the purpose set forth.



605,766. HORSESHOE-CALK. RICHARD WHITAKER, New Brunswick, N. J., assignor to the Novelty Manufacturing Company, same place. Filed Feb. 26, 1898. Serial No. 671,788. (No model.)

Claim.—1. A removable horseshoe-calk consisting of a polygonal tubular shell having an inwardly-projecting collar on its upper end, in combination with a polygonal-headed screw having the flat projecting part of its head adjacent to its body bearing against said collar and its faces in engagement with the polygonal inner sides of the calk, substantially as described.

2. A horseshoe-calk consisting of a tubular shell having an inwardly-projecting collar on its upper end and a hollow polygonal head on top of said collar, substantially as described.

605,767. COMBINED PLOW, PLANTER, AND CULTIVATOR. CHARLES H. WHITNEY, Cookeville, Tenn. Filed Feb. 4, 1898. Serial No. 669,056. (No model.)

Claim.—1. In a machine of the class described, the combination of a frame, a wheel supporting said frame, axles carried by the wheel and journaled in bearings the outer ones of which are laterally removable whereby the ends of the axle may be free, seed-rings slidably adjustable and removably mounted on the axles, seed-hoppers above the rings, and drills at said rings adjustably secured to the frame, substantially as set forth.

2. In a machine of the class described, the combination of a frame, a wheel supporting said frame, axles carried by the wheel and journaled in bearings the outer ones of which are laterally removable whereby the ends of the axle may be free, seed-rings adjustably and removably mounted on the axles, seed-hoppers above the rings having deflectors and brushes as described, and drills having concaved upper ends located at the rings, said drills being adjustably and removably secured to the frame, substantially as set forth.

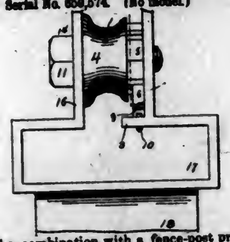
3. In a machine of the class described, the combination of a frame, a wheel supporting said frame, axles carried by the wheel and journaled in bearings the outer ones of which are laterally removable whereby the ends of the axles may be free, seed-rings mounted on the axles to be adjusted and removed longitudinally thereof, each seed-ring having seed-cups and set-screws therein to adjust the depth thereof, seed-hoppers above the rings, drills at said rings, coverers at the rear of the drills, and means for adjustably and removably attaching said drills and coverers to the frame to permit of vibration, substantially as described.

4. In a machine of the class described, the combination with a frame carrying transverse rods, of a drill provided at its upper end with a hook slidably and removably connected with one of the rods, a plate slidably connected with the other rod and carrying a set-screw and staple, an eye on the drill engaging the staple, and a break-pin for the latter, substantially as described.

5. In a machine of the class described, the combination with a frame and a single supporting-wheel therefor, of a caster-wheel in advance of the aforesaid wheel, a lever for elevating and depressing said wheel as described, and means for locking the lever in its positions, substantially as set forth.

6. In a machine of the class described, the combination with a frame and a single supporting-wheel therefor, of a caster-wheel in advance of the aforesaid wheel, carried by an arm, a lever connected to said arm, a brake-shoe carried by the lever and adapted to be brought into engagement with the supporting-wheel when the caster-wheel is depressed, and means for locking the lever consisting of a slotted guide having offsets provided with inclined sides, substantially as described.

605,768. LAST. ELBERT C. WRIGHT, Brockton, Mass. Filed May 22, 1897. Serial No. 637,857. (No model.)

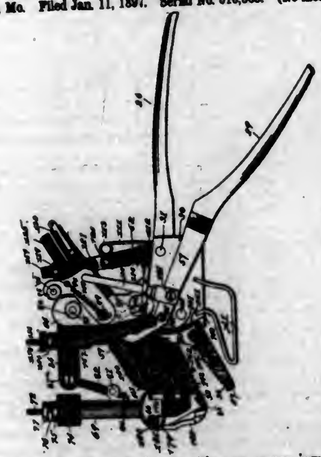


Claim.—1. The combination with a last and its socket, of a socket-supporting truss member extending transversely through the last in vertical alinement below said socket, constructed to provide resistance to endwise leward movement of the ends of said truss member thereby to resist transverse depression of said truss member between its ends under the settling tendency of said socket.

2. In a last, having a socket, a pressure-resistance member extending transversely of and from side to side of the last to constitute a combined support for the bottom of the socket and stay or binder for the sides, each end thereof having a laterally-extended abutment countersunk in the side of the last, substantially as described.

605,769. COMBINED POST AND WINDING APPARATUS.

WILLIAM L. YERKES and JOHN R. WADSWORTH, La Porte, Ind. Filed Nov. 30, 1897. Serial No. 659,574. (No model.)



Claim.—1. The combination with a fence-post provided with a lip or flange, of a winding-drum provided with a ratchet and mounted in said post, a gravity-pawl resting against said lip or flange and means carried by the post to limit the movement of said pawl, all arranged as set forth.

2. The combination with a fence-post having a pin, of a winding-drum provided with a ratchet and mounted in said post, and a gravity-pawl having a recess in which said pin works to limit the movement of said pawl, all arranged as set forth.

3. A fence having separate vertical posts, one of said posts having a lip 3, devices located between said posts and connecting the same, and a gravity-pawl resting against said lip designed to control the movement of said devices, all combined as set forth.

605,770. HAND LASTING-MACHINE.

GEORGE H. ABEEL, St. Louis, Mo. Filed Jan. 11, 1897. Serial No. 618,865. (No model.)

Claim.—1. In a hand lasting-machine, an upper jaw, a handle rigidly connected to said upper jaw, a lower jaw pivotally mounted in position to engage said upper jaw, a lever pivotally mounted in position to operate said lower jaw, a handle hinged to the end of said lever opposite the end which engages said lower jaw, an arm projecting forwardly from said last-mentioned handle, and a yielding connection between said arm and the first-mentioned handle, whereby said lower jaw is yieldingly operated by the opposition of said last-mentioned handle, substantially as specified.

2. In a hand lasting-machine, a suitable frame, an upper jaw rigidly connected to said frame, a handle rigidly connected to said frame, a lower jaw pivotally mounted in position to engage said upper jaw, a lower handle pivotally connected to said frame, and a yielding connection between said lower handle and said lower jaw, substantially as specified.

3. In a hand lasting-machine, an upper jaw having a rigid handle, a lower jaw pivotally mounted in position to engage said upper jaw, a second handle mounted to yieldingly operate said lower jaw, a tubular block rigidly connected to said upper jaw, a plunger operating in said block, a hammer carried by said plunger, connections between said plunger and said second handle whereby the hammer is elevated and caused to rebound by the operation of said second handle, and a tack-chute leading to a point within said tubular block and below said hammer when in its elevated position, substantially as specified.

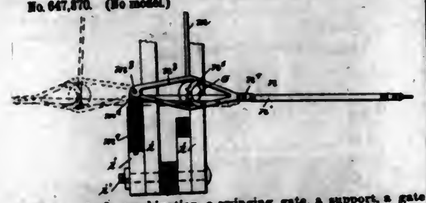
4. In a hand lasting-machine, a suitable frame, an upper jaw rigidly connected to said frame, a lower jaw pivotally mounted in position to engage said upper jaw, a lever pivotally mounted in said frame and operating said lower jaw, a lower handle hinged to said lever, a yielding connection between said lower handle and said frame whereby the lower jaw is yieldingly operated and a foot extending from said frame below said lower jaw, substantially as specified.

5. In a hand lasting-machine, a suitable frame, an upper jaw rigidly connected to said frame, a tubular block mounted in position above the point of said upper jaw, a hammer operating in said tubular block, a tack-chute leading into said tubular block below said hammer, a lower jaw pivotally mounted in position to engage said upper jaw, a lever pivotally mounted in said frame and operating said lower jaw, a lower handle hinged to said lever, a second lever pivotally mounted above said rigid jaw, a connection between the front end of said second lever and said hammer, an arm projecting forwardly from said lower handle, a yielding connection between the forward end of said second lever and said arm, and a trigger connection between the rear end of said second lever and said arm, substantially as specified.

6. In a hand-lasting machine, a suitable frame, an upper jaw rigidly connected to said frame, a tubular block mounted in position above the point of said upper jaw, a hammer operating in said tubular block, a tack-chute leading into said tubular block below said hammer, a lower jaw pivotally mounted in position to engage said upper jaw, a lever pivotally mounted in said frame and operating said lower jaw, a lower handle hinged to said lever, a second lever pivotally mounted above said rigid jaw, a connection between the front end of said second lever and said hammer, an arm projecting forwardly from said lower handle, a yielding connection between the forward end of said second lever and said arm, a trigger connection between the rear end of said second lever and said arm, a picker mounted to slide horizontally and feed tacks one at a time from said tack-chute into said block, a connection between the forward end of said second lever and said picker whereby the picker is pressed forwardly and a projection carried by said picker to engage the forward end of said arm and hold the picker in position to close the throat in said tubular block while the tack is being driven, substantially as specified.

7. In a hand lasting-machine, a suitable frame, the upper jaw 25, the handle 26 formed integral with said upper jaw, the lower jaw 27 pivotally mounted in an operative position relative to said upper jaw, the lever 28 pivotally mounted in position to form a knuckle-joint with the rear end of the jaw 27, the handle 29 hinged to the rear end of said lever 28, the foot 41 mounted in position below the lower jaw, the arm 57 projecting forwardly from the handle 29 and a yielding connection between the forward end of said arm and the frame of the machine, substantially as specified.

8. In a hand lasting-machine, the upper jaw 25, having the slot 141 formed in its front face in a substantially horizontal line, the tubular block 66 rigidly connected to said jaw, a tack-chute leading into said tubular block, the picker-bar 142 slidingly mounted in said slot 141, the picker 145 attached to the front end of the picker-bar, the shipper-bar 146 mounted for vertical reciprocation and the lug 165 projecting outwardly from the picker-bar and engaging the front face of the shipper-bar and in position to engage the front end of the arm 57, substantially as specified.



9. In a hand lasting-machine, the picker-bar 142 slidingly mounted in a horizontal position, the shipper-bar 146 mounted for vertical reciprocation, the lug 165 projecting from the picker-bar and engaging the front face of the shipper-bar and the spring 160 connecting said picker-bar with said shipper-bar, substantially as specified.

10. In a hand lasting-machine, the picker-bar 142 slidingly mounted in a horizontal position, means for operating said bar, the picker 145 attached to the front end and inner face of said bar, the lugs 170 and 171 formed upon the upper and lower faces of the forward end of said bar, the picker-shifter 172 yieldingly mounted, the diagonal lugs 175 and 176 carried by said picker-shifter in position to be engaged by the lugs 170 and 171 carried by the picker-bar, substantially as specified.

11. In a hand lasting-machine, the lever 84 pivotally mounted, the segmental portion 89 arranged concentric to the pivot of said lever and projecting downwardly, the ratchet-teeth 90 formed upon the lower edge of said segment, said teeth pointing downwardly and backwardly, the pawl 91 pivotally mounted in position to engage said teeth, means for operating said lever, and means of operating said pawl, substantially as specified.

605,771. GATE.

JOSHUA F. BARNES, Shannon, Ill., assignor of one-half to Henry B. Gaull, same place. Filed Aug. 11, 1897. Serial No. 647,870. (No model.)

Claim.—1. In combination, a swinging gate, a support, a gate opening and closing toggle loosely joined to the support and gate, said toggle comprising a member joined at one end to the support and at the opposite end to an intermediate portion of the longer member which is joined to the gate, said longer member beside and parallel with the short member and resting on and upheld by said support when the gate is both completely opened and closed, one member having a cross-head on which the other member closes when the gate is opened and closed, and toggle-actuating means connected with said cross-head, substantially as described.

2. In combination, a swinging gate, a support, a tarn-head on the support, a gate opening and closing toggle comprising a member joined to the gate and having a longitudinal opening, a power member in the opening of said member and at one end pivoted to said tarn-head and at the other end pivoted to said first-mentioned member a distance inwardly from the free end thereof so that said power member lies within and parallel with said first-mentioned member which rests on said tarn-head when the gate is completely opened and closed, and toggle-actuating means, substantially as described.

3. In combination, a swinging gate, a support, a gate opening and closing toggle comprising a long member loosely joined to the gate and a short member loosely joined to the support and at one end joined to an intermediate point of the long member so that said members are side by side and parallel when the gate is completely opened and closed, a cross-head confined to the short member and beneath and down on which the long member closes, and toggle-actuating means connected to said cross-head.

4. A gate and its posts, in combination with an upright triangular supporting-frame, arranged beside the gate, means for opening and closing the gate coupled to the lower portion of said frame, sweeps pivoted at the upper horizontal portion of said frame with their inner ends arranged about at the central portion of said upper horizontal part of the frame and loosely connected to said gate-operating means, substantially as described.

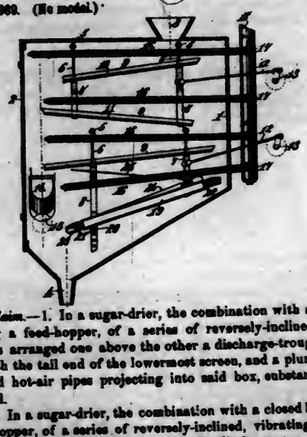
5. A gate, in combination with two parallel upright posts, a sill connecting the lower portions thereof, an upright triangular supporting-frame having two inclined sides meeting and secured together at or about the center of said sill, said sides also secured respectively to the upper portions of the posts and having their upper ends connected by the horizontal sides, gate opening and closing means connected to said frame, and sweeps controlling said means and mounted at the upper corners of said frame, substantially as described.

6. In combination, a swinging gate, a supporting-frame adjacent thereto, a gate opening and closing toggle, a connection provided with toggle-operating means, said connection having a loose eccentric connection with one member of the toggle for the purpose substantially as described.

7. A swinging gate having a gate opening and closing toggle, a toggle-actuating connection having operating means, and a shifting eccentric connection between said toggle and said actuating connection, combined substantially as described.

8. In combination, a swinging gate, a support, a gate opening and closing toggle comprising a long lever with a longitudinal opening coupled to the gate, a short power-lever coupled to the support and arranged within said opening of the long lever and pivoted thereto and arranged in and parallel with said long lever when the gate is closed and when at its limit of opening swing, and operating means loosely joined to said power-lever, substantially as described.

9. In combination, a swinging gate, a support, a gate opening and closing toggle having one member loosely joined to the gate and the other member loosely joined to the support, one member having a wheel mounted to turn therein, an operating connection eccentrically and loosely connected to said wheel, and actuating means for said connection, substantially as described.



10. In combination, a swinging gate, a support, a gate opening and closing toggle comprising the long lever coupled to the gate and formed with the longitudinal opening, the short power-lever within said opening and at one end pivoted to said long lever at a distance from its outer end and at its opposite end pivoted to the support, and an operating connection having a cross-head beneath and against which the long lever locks, which cross-head is loosely and eccentrically joined to the power-lever, substantially as described.

11. In combination, a gate, a support, a gate opening and closing toggle comprising a member coupled to the gate and a power-lever coupled to the support and having an open central portion, a rotary wheel mounted in said open central portion, a cross-shaft eccentrically mounted in said wheel and against which said member is arranged to lock or rest when the gate is completely opened or closed, and an operating connection confined to said cross-shaft, substantially as described.

12. In combination, a swinging gate, a support, a gate-operating toggle confined to the gate and the support and comprising members of unequal lengths, one member joined to the other at an intermediate point thereof, and toggle-actuating means provided with a cross-head confined at an intermediate point in one member so that the other member closes down thereon when the gate is open and closed, substantially as described.

605,772. SUGAR-DRIER.

LOUIS J. BARTHELEMY and ARISTIDE L. BARTHELEMY, New Orleans, La. Filed Mar. 30, 1897. Serial No. 629,969. (No model.)

Claim.—1. In a sugar-drier, the combination with a closed box having a feed-hopper, of a series of reversely-inclined, vibrating screens arranged one above the other a discharge-trough arranged beneath the tail end of the lowermost screen, and a plurality of perforated hot-air pipes projecting into said box, substantially as described.

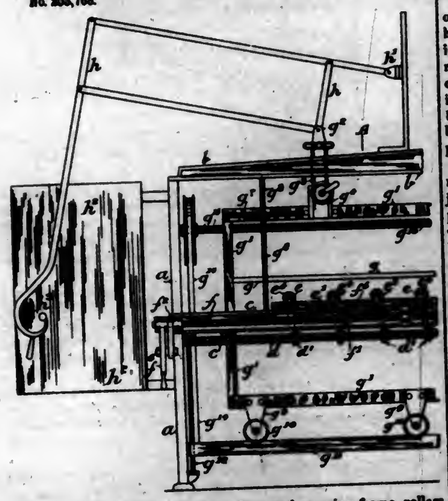
2. In a sugar-drier, the combination with a closed box having a feed-hopper, of a series of reversely-inclined, vibrating screens arranged one above the other, a vibrating discharge-trough arranged beneath the tail end of the lowermost screen, and a plurality of perforated hot-air pipes projecting into said box, substantially as described.

3. In a sugar-drier, the combination with a closed box having a feed-hopper, of a series of reversely-inclined, vibrating screens arranged one above the other, a discharge-trough arranged beneath the tail end of the lowermost screen, and an inclined steam-box arranged beneath said lowermost screen, substantially as described.

4. In a sugar-drier, the combination with a closed box having a feed-hopper, of a series of reversely-inclined, vibrating screens arranged one above the other, a discharge-trough arranged beneath the tail end of the lowermost screen, and an inclined vibrating steam-box arranged beneath said lowermost screen, substantially as described.

5. In a sugar-drier, the combination with a closed box having a feed-hopper, of a series of reversely-inclined vibrating screens arranged one above the other, a discharge-trough arranged beneath the tail end of the lowermost screen, an inclined steam-box arranged beneath said lowermost screen, and a plurality of perforated hot-air pipes projecting into said closed box, substantially as described.

6. In a sugar-drier, the combination with a closed box having a feed hopper 3 and a discharge-spout 4, of the cross-rods 5 fixed in the sides of the box, the hangers 6 suspended therefrom, the brackets 7 8 pivoted to said hangers, the frames 9 fixed to the upper and lower ends of said brackets and carrying screens, cranks 13, and connecting-rods 12 attached to the brackets 8, substantially as described.



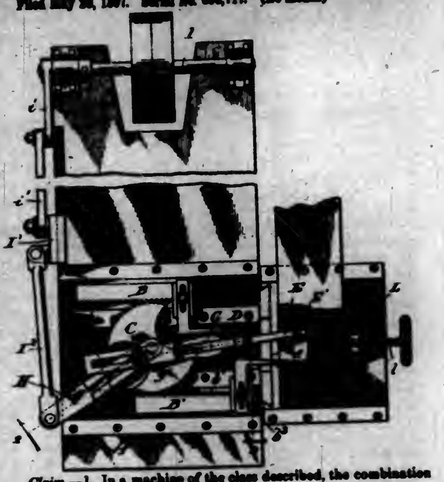
7. In a sugar-drier, the combination with a closed box having a feed-hopper 3 and a discharge-spout 4, of a series of reversely-inclined vibrating screens arranged one above the other, a discharge-trough arranged transversely to and beneath the tail end of the lowermost screen, said trough being hinged at one end to the side of the box and projecting at its other end through an aperture in the opposite side, and an eccentric engaging and supporting the free end of said trough, substantially as described.

8. In a sugar-drier, the combination with a closed box having a feed-hopper 3 and discharge-spout 4, of a series of reversely-inclined vibrating screens arranged one above the other, a discharge-trough arranged beneath the tail end of the lowermost screen, and an inclined steam-box 19 supported at its upper end in the lowermost bracket 8 and adjustably attached at its lower end to the corresponding bracket 7, and means for vibrating said brackets, substantially as described.

9. In a sugar-drier, the combination with a closed box having a feed-hopper 3 and a discharge-spout 4, of a series of reversely-inclined vibrating screens arranged one above the other, a discharge-trough arranged beneath the tail end of the lowermost screen, and an inclined steam-box 19 supported at its upper end in the lowermost bracket 8 and having attached to the under side of its opposite end perforated lugs 20 attached to the brackets 7 by bolts 21, nipples 22 and 23 at the upper and lower ends of said steam-box, vertical flanges 24 at the sides of the steam-box, and means for vibrating the steam-box substantially as described.

10. In a sugar-drier, the combination with a closed box having a feed-hopper 3 and discharge-spout 4, of a series of reversely-inclined vibrating screens arranged one above the other, a discharge-trough arranged beneath the tail end of the lowermost screen, an inclined shelf 25 arranged beneath said lowermost screen, and a vibrating steam-box disposed beneath said shelf, substantially as described.

605,773. CARVING-MACHINE. William Berry, Nottingham, England. Filed Sept. 27, 1897. Serial No. 653,194. (No model.) Patented in England Nov. 5, 1894, No. 21,168, and in France Feb. 7, 1896, No. 253,768.



Claim.—1. The combination of a wood-carrying frame, rollers attached thereto, a bar for the rollers to run on, guides for the bar, balance-weights attached to the bar by flexible bands, pulleys for the bands to run over, roller-guides for the upper part of the frame a pantograph arrangement of levers and rotating cutters substantially as described.

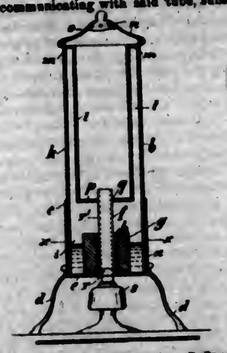
2. The combination of a wood-carrying frame, rollers, roller-bar, guides and balance-weights for the frame, a pantograph arrangement of levers a rack and slide between the frame and pantograph, rotating cutters, a cutter-spindle frame adjustable longitudinally on a bed fitted to slide transversely on fixed pins lever for adjusting the relative positions of the bed and frame and a shaft for driving the cutters substantially as described.

3. The combination of a wood-carrying frame fitted to move in any direction in the same plane, rollers attached thereto, a bar for the rollers to run on guides which permit the bar to move vertically, weights for balancing the frame and attached to the bar supporting it by flexible bands which pass over pulleys on a shaft, roller-guides for the upper part of the frame, a pantograph for moving the frame, a slide-and-rack connection, rotating cutters carried by a spindle which runs in brackets longitudinally adjustable on a bed transversely adjustable relatively to the frame, levers for moving the bed, means for holding the bed, and a cutter-spindle-driving shaft substantially as described.

605,774. MORTISING-MACHINE. Walter Blake, Chicago, Ill. Filed May 20, 1897. Serial No. 638,717. (No model.)

Claim.—1. In a machine of the class described, the combination of two reciprocating slides having racks thereon and arranged to hold projecting cutter portions in line with their motion, an oscillating-gear portion mounted between the same and engaging with the racks on the slide to impart the desired reciprocating motion, a pivotal tool-holder mounted independently and adjacent to the oscillating gear and provided with an extending-arm portion such holder being arranged to vibrate a cutter, and means for securing the vibrating-cutter-holder portion to the gear portion whereby the desired proportional motions are given such parts, substantially as described.

2. In a machine of the class described, the combination of two reciprocating slides having racks thereon and arranged to hold projecting cutter portions in line with their motion, an oscillating-gear portion mounted between the same and engaging with the racks on the slide to impart the desired reciprocating motion, a pivotal tool-holder mounted independently and adjacent to the oscillating gear and provided with an extending-arm portion such holder being arranged to vibrate a cutter at right angles to the movement of the slides, means for securing the vibrating-cutter-holder portion to the gear portion whereby the desired proportional movements are given to such parts, means for holding the material, means for adjusting the material to the desired position, and means for feeding the material-holder with the material into contact with the cutters, substantially as described.



3. In a machine of the class described, the combination of two reciprocating slides having racks thereon, cutter portions adjustably secured to the rack-slides, an oscillating-gear portion mounted between the racks and engaging with the same so as to impart the desired reciprocating motion to the slides, a pivotal tool-holder mounted independently and adjacent to the oscillating gear and provided with an extending-arm portion, such holder being arranged to vibrate a cutter, and means for adjustably securing the vibrating cutter-holder to the gear portion so as to obtain variable vibratory motions of the vibrating cutter, substantially as described.

605,775. STEAM-RADIATOR. Carl Bodmer, Odessa, Russia. Filed May 1, 1897. Serial No. 634,703. (No model.)

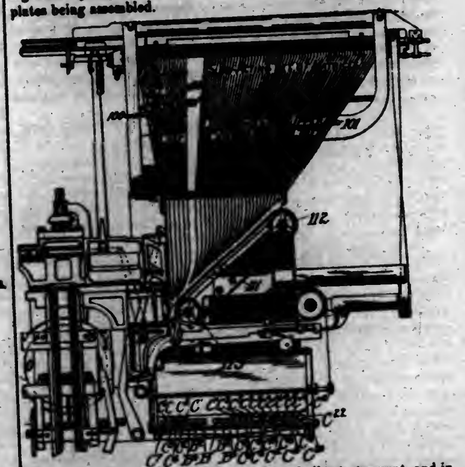
Claim.—1. In a steam-radiator, the combination with a reservoir of a radiator communicating therewith, a generator located in said reservoir and provided with a central opening, a tube extending though said opening and of smaller diameter than the same forming an annular chamber communicating with said reservoir, and a source of heat communicating with said tube, substantially as set forth.

2. In a steam-radiator, the combination with a reservoir, of a radiator communicating therewith, a generator located in said reservoir and having channels in its under surface and provided with a central opening, a tube of smaller diameter located within said opening and communicating with a perforation in the bottom of the reservoir and a source of heat communicating with said tube, substantially as set forth.

3. In a steam-radiator, the combination with a reservoir of a radiator communicating therewith, a generator located in said reservoir and channeled upon its under surface and provided with a central opening, a tube of smaller diameter located within said opening and communicating at its lower end with an opening in the bottom of the reservoir, a cylinder located within the radiator and provided with an opening in its base through which the said tube extends, and a source of heat communicating with said tube, substantially as set forth.

605,776. TREE-PROTECTOR. John R. Brader, Ronan, Iowa. Filed Aug. 27, 1897. Serial No. 649,748. (No model.)

Claim.—A tree-protector, composed of the woven wire A, the metal binding-strip B having an extension B^2, and fixed studs a, a', and a'', a metal binding-strip C, cross-wires d, d', and d'', terminating in hooks f, f', f'', and a flexible piece of fabric H fixed to the top of the woven wire A, as and for the purposes stated.



605,777. LINOTYPE-MACHINE, LINE-CASTING MACHINE, AND MACHINE FOR MAKING TYPE-BARS, LINOTYPES, AND MATRICES. Theodore Cahill, New York, N. Y. Original application filed Oct. 31, 1896, Serial No. 610,489. Divided and this application filed Aug. 11, 1897. Serial No. 647,982. (No model.)

Claim.—1. In a line-casting machine or other similar instrument, two sets of circulating matrices or type-plates of the same case and face in combination with composing mechanism constructed to assemble matrices or type-plates of the two sets aforesaid in due order into the same line.

2. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including two sets of circulating matrices or type-plates of the same case and composing mechanism, whereby matrices or type-plates of the two sets aforesaid are simultaneously arranged in due order in a line.

3. In a line-casting machine or other similar instrument, two sets of circulating matrices or type-plates of the same case and face in combination with composing mechanism constructed to assemble matrices or type-plates of the two sets aforesaid in due order into the same line; the matrices or type-plates of one of the two sets aforesaid being normally disposed in proximity to the line of matrices or type-plates being assembled, and the matrices or type-plates of the other set aforesaid being normally disposed more remote from the line of matrices or type-plates being assembled.

4. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including in combination with suitable composing mechanism, two sets of circulating matrices or type-plates of the same case; the matrices or type-plates of the one set being normally disposed in proximity to the line of matrices or type-plates being assembled, and the matrices or type-plates of the other set being normally disposed more remote from the line of matrices or type-plates being assembled.

5. In a line-casting machine or other similar instrument, and in combination, two sets of circulating matrices or type-plates of the same case and face; the matrices or type-plates of one set being normally disposed in proximity to the line of matrices or type-plates being assembled, and the matrices or type-plates of the other set being normally disposed more remote from the line of matrices or type-plates being assembled; releasing devices for the set of matrices or type-plates above mentioned as disposed in proximity to the line of matrices or type-plates being assembled; keys controlling said releasing devices; other releasing devices for the other set of matrices or type-plates above mentioned, and other keys controlling said releasing devices; and means constructed to assemble the matrices released from the two sets aforesaid in due order in the same line.

6. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including in combination with suitable composing mechanism, two sets of circulating matrices or type-plates of the same case; the matrices or type-plates of one set being normally disposed in proximity to the line of matrices or type-plates being assembled, and the matrices or type-plates of the other set being normally disposed more remote from the line of matrices or type-plates being assembled; releasing devices for the set of matrices or type-plates above mentioned as disposed in proximity to the line of matrices or type-plates being assembled; keys controlling said releasing devices; other releasing devices for the other set of matrices or type-plates above mentioned, and other keys controlling said releasing devices; the whole being constructed, arranged and operating in such a manner that when matrices or type-plates of the two sets aforesaid are released by or in consequence of simultaneous actions of the operator upon keys of the two sets aforesaid, one matrix or type-plate from each set the matrix or type-plate released from the set of matrices or type-plates before mentioned as being disposed in proximity to the line of matrices or type-plates being assembled, reaches a position in the line of matrices or type-plates being assembled, in advance of the matrix or type-plate of the other set, released by the simultaneous action of the operator; so that two matrices or type-plates released by or in consequence of simultaneous actions of the operator, follow each other in due order in the line of matrices or type-plates being assembled.

7. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including (a) two sets of matrices or type-plates of the same case; (b) primary-letter-releasing devices, whereby the matrices or type-plates corresponding to the first letters of the

consecutive pairs of letters are released; (*c*) secondary-letter-releasing devices, whereby the matrices or type-plates corresponding to the second letters of the consecutive pairs of letters are released; and (*d*) suitable composing mechanism, whereby the matrices or type-plates of the two sets aforesaid are simultaneously assembled into line; the whole being constructed, arranged and operating in such a manner that when matrices or type-plates of the two sets are released by or in consequence of simultaneous actions of the operator, one matrix or type-plate from each set, the matrix or type-plate released by the primary-letter-releasing devices reaches a position in the line of matrices or type-plates being assembled, in advance of the matrix or type-plate of the other set, released by the secondary-letter-releasing devices; so that the two matrices or type-plates released by or in consequence of simultaneous actions of the operator are made to follow each other in due order in the line of matrices or type-plates being assembled.

8. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including in combination with suitable composing mechanism, two sets of matrices or type-plates of the same case; the matrices or type-plates of one set being disposed in proximity to the assembling-block, and the matrices or type-plates of the other set being disposed more remote from the assembling-block.

9. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including in combination with suitable composing mechanism, two sets of matrices or type-plates of the same case; the matrices or type-plates of one set being disposed in proximity to the assembling-block, and the matrices or type-plates of the other set being disposed more remote from the assembling-block; releasing devices for the set of matrices or type-plates above mentioned as disposed in proximity to the assembling-block; keys, controlling said releasing devices; other releasing devices for the other set of matrices or type-plates above mentioned; and other keys controlling said releasing devices; the whole being constructed, arranged and operating in such a manner that when matrices or type-plates of the two sets are released by or in consequence of simultaneous actions of the operator, one matrix or type-plate from each set, the matrix or type-plate released from the set of matrices or type-plates before mentioned as being disposed in proximity to the assembling-block, reaches a position in the line of matrices or type-plates being assembled, in advance of the matrix or type-plate of the other set, released by the simultaneous action of the operator; so that two matrices or type-plates released by or in consequence of simultaneous actions of the operator, follow each other in due order in the line of matrices or type-plates being assembled.

10. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including two sets of matrices of type-plates of the same case, to wit, a set of primary-letter matrices or type-plates and a set of secondary-letter matrices or type-plates, in combination with suitable composing mechanism whereby matrices or type-plates of the two sets aforesaid are simultaneously assembled into the same line.

11. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including in combination with suitable composing mechanism, two sets of matrices or type-plates of the same case, to wit, a set of primary-letter matrices and a set of secondary-letter matrices; keys and releasing mechanism controlled by them, operating to release the primary-letter matrices or type-plates aforesaid; other keys and releasing devices controlled by them, operating to release the secondary-letter matrices or type-plates aforesaid; and means operating when keys of the two sets aforesaid are acted upon simultaneously by the operator; thereby to release two matrices, or type-plates, one from each of the two sets of matrices or type-plates above mentioned, to cause the matrix or type-plate released from the primary-letter set of matrices or type-plates, to reach a position in the line of matrices or type-plates being assembled in advance of the matrix or type-plate released, by or in consequence of the simultaneous action of the operator upon the appropriate key or keys, from the secondary-letter set of matrices or type-plates.

12. In a line-casting machine or other similar instrument, two sets of matrices or type-plates of the same case and face, in combination with composing mechanism, including (*a*) a set of keys for the right hand, controlling one of the two sets of matrices or type-plates above mentioned (*b*), a set of keys for the left hand, controlling the other set of matrices or type-plates above mentioned, and (*c*) means constructed to assemble matrices or type-plates of the two sets aforesaid, in due order in the same line.

13. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including two sets of matrices or type-plates of the same case, to wit, a set of primary-letter matrices or type-plates, and a set of secondary-letter matrices or type-plates in combination with suitable composing mechanism, including a set of keys for the right hand, controlling one of the two sets of matrices or type-plates above mentioned, and a set of keys for the left hand, controlling the other set of matrices or type-plates above mentioned; and means operating when keys of the two sets aforesaid are acted upon simultaneously by the operator, thereby to release two matrices or type-plates, one from each of the two sets above mentioned, to cause the matrix or type-plate released from the primary-letter set of matrices or type-plates to reach a position in the line of matrices or type-plates being assembled in advance of the position reached by the matrix or type-plate released by the simultaneous action of the operator, from the secondary-letter set of matrices or type-plates.

14. In a line-casting machine or other similar instrument, and in combination, (*a*) two sets of matrices or type-plates of the same case and face; (*b*) a set of keys and releasing mechanism controlled by said keys and acting to release the matrices or type-plates of one of the two sets aforesaid; (*c*) another set of keys, and releasing mechanism controlled by said last-mentioned keys, and acting to release the matrices or type-plates of the other one of the two sets aforesaid; and (*d*) additional composing mechanism constructed to assemble the matrices or type-plates released from the two sets aforesaid, in due order in the same line.

15. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including (*a*) two sets of matrices or type-plates of the same case; (*b*) a set of keys and releasing mechanism controlled by said keys, acting to release the matrices or type-plates of one of the two sets aforesaid; (*c*) another set of keys and releasing mechanism controlled by said last-mentioned keys, acting to release the matrices or type-plates of the other one of the two sets aforesaid; and (*d*) additional composing mechanism whereby the matrices or type-plates released from the two sets aforesaid are arranged in due order in the line; the whole being constructed arranged and operating in such a manner that when keys of the two sets aforesaid are depressed by the operator simultaneously, thereby to free one matrix or type-plate of each set, the matrices or type-plates released, belonging to one set and controlled by the one set of keys, are regularly assembled or disposed in advance, in the line of the matrices or type-plates released simultaneously or substantially simultaneously, but belonging to the other set of matrices or type-plates and controlled by the other set of keys aforesaid.

16. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including (*a*) two sets of matrices or type-plates of the same case; (*b*) a set of keys for the right hand, and releasing mechanism controlled by said keys and acting to release the matrices or type-plates of one of the two sets aforesaid; (*c*) a set of keys for the left hand and releasing mechanism, controlled by said keys, and acting to release the matrices or type-plates of the other one of the two sets aforesaid; and (*d*) additional composing mechanism whereby the matrices or type-plates released from the two sets aforesaid are arranged in due order in the line; the whole being constructed, arranged and operating in such a manner that when keys of the two sets aforesaid are depressed by the operator simultaneously, thereby to free one matrix or type-plate of each set, the matrices or type-plates released belonging to one set and controlled by the one set of keys, are regularly assembled or disposed in advance, in the line of matrices or type-plates, and controlled by the other set of keys, by the simultaneous acting of the operator upon the other set of keys.

17. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including (*a*) a set of keys adapted to be operated by the right hand, and a set of lower-case matrices or type-plates controlled by such keys; (*b*) a set of keys adapted to be operated by the left hand and another set of lower-case matrices or type-plates controlled by such left-hand keys; (*c*) means controlled by the right-hand keys, acting to release the matrices or type-plates of the one set, each as required; (*d*) means, controlled by the left-hand keys, acting to release the matrices or type-plates of the other set, each as required; and (*e*) additional composing mechanism whereby the matrices or type-plates released, of the two sets aforesaid are arranged, in due order in the line; the whole being constructed, arranged and operating in such a manner that when keys of the two sets aforesaid are depressed by the operator simultaneously, thereby to free one matrix or type-plate of each set, the matrices or type-

plates released, belonging to the one set of matrices or type-plates, and controlled by the one set of keys, are regularly assembled or disposed in advance, in the line, of the matrices or type-plates released by or in consequence of a simultaneous action of the operator, but belonging to the other set of matrices or type-plates and controlled by the other set of keys aforesaid.

18. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including in combination, (*a*) two sets of matrices or type-plates of the same case; (*b*) releasing devices for each set of matrices or type-plates; (*c*) two sets or groups of keys; (*d*) quick-acting connections between the keys of one set and the releasing devices controlling one of the sets of matrices or type-plates before mentioned; and (*e*) slow-acting connections between the keys of the other set and the releasing devices controlling the matrices or type-plates of the other set, before mentioned.

19. In a line-casting machine and in combination, (*a*) two sets of matrices or type-plates of the same case and face; (*b*) a set of keys and releasing devices controlled thereby, and acting to control the matrices or type-plates of one of the two sets aforesaid; (*c*) another set of keys and other releasing devices controlled by said keys, and acting to control the matrices or type-plates of the other one of the two sets aforesaid; (*d*) a conveyer in operative relation to the matrices of the two sets aforesaid, and serving to convey the matrices or type-plates of the two sets aforesaid, when they are released, to the mechanism for arranging them in line, and (*e*) means constructed to assemble the matrices or type-plates released from the two sets aforesaid in due order into a line.

20. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including in combination with mechanism for arranging the matrices or type-plates in line, (*a*) two sets of matrices or type-plates of the same case; (*b*) two sets of keys; (*c*) releasing devices for each set of matrices or type-plates, controlled by the corresponding set of keys; and (*d*) a carrier serving to convey the matrices or type-plates of the two sets aforesaid, after they have been released, to the mechanism before mentioned for arranging them in line; the matrices or type-plates of the two sets aforesaid being disposed in such relation to the carrier before mentioned that the matrices or type-plates of the one set regularly fall upon said carrier nearer to the mechanism before mentioned for arranging the matrices or type-plates in line, (and to which mechanism the matrices or type-plates are being conveyed by the carrier,) than the matrices or type-plates do of the other set, released by a simultaneous action of the operator.

21. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including (*a*) two sets of matrices or type-plates of the same case; (*b*) releasing devices for each set of matrices or type-plates; (*c*) two sets of keys; (*d*) quick-acting connections between one set of keys and the releasing devices controlled by said keys and which serve to control one of the two sets of matrices or type-plates aforesaid; (*e*) slow-acting connections between the other set of keys aforesaid and the releasing devices controlled by such keys and which serve to control the other set of matrices or type-plates aforesaid; and (*f*) a carrier, serving to convey the matrices or type-plates of the two sets aforesaid, when they are released, to the mechanism whereby they are arranged in line; the matrices or type-plates of the two sets aforesaid being disposed in such relation to the carrier before mentioned that the matrices of the set whose releasing devices are connected with the keys controlling them by quick-acting connections, regularly fall upon said carrier nearer to the mechanism before mentioned whereby said matrices are arranged or composed in line, and to which mechanism the matrices or type-plates are being conveyed by the carrier aforesaid, than the matrices or type-plates do of the other set, whose releasing devices are connected with the keys controlling them by slow-acting connections.

22. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including in combination, with suitable composing or assembling mechanism, (*a*) two sets of matrices or type-plates of the same case; (*b*) releasing devices for each of the sets of matrices or type-plates aforesaid; (*c*) two sets of keys; (*d*) quick-acting connections between one set of keys aforesaid and the releasing devices controlling one of the sets of matrices or type-plates aforesaid; and (*e*) slow-acting connections between the other set of keys aforesaid and the releasing devices controlling the other set of matrices or type-plates aforesaid; the set of matrices or type-plates aforesaid whose releasing devices are connected with the keys controlling them by quick-acting connections, being disposed in proximity to the line of matrices or type-plates being assembled, and the matrices or type-plates of the other set, whose releasing devices are connected with the keys controlling them by slow-acting connections, being disposed more remote from the line of matrices or type-plates being assembled.

23. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including (*a*) two sets of matrices or type-plates of the same case; (*b*) releasing devices, for the two sets of matrices or type-plates aforesaid, whereby the matrices or type-plates of each set are released, as required; (*c*) two sets of keys, serving to control the two sets of matrices or type-plates aforesaid; and (*d*) permutational selecting devices intermediate at least one set of keys and the releasing devices controlled thereby; whereby a few keys are made to control a large number of releasing devices, each as required.

24. In a line-casting machine or other similar instrument, and in combination, (*a*) two sets of matrices or type-plates of the same case; (*b*) releasing devices for the two sets of matrices or type-plates aforesaid, whereby the matrices or type-plates of each set are released, as required; (*c*) two sets of keys serving to control the two sets of matrices or type-plates aforesaid, respectively; (*d*) permutational selecting devices intermediate one set of keys at least, and the releasing devices controlled thereby, whereby a few keys are made to control a large number of releasing devices, each as required; and (*e*) means constructed to assemble the matrices or type-plates released from the two sets aforesaid in due order into a line.

25. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including (*a*) two sets of matrices or type-plates of the same case; (*b*) releasing devices for the two sets of matrices or type-plates aforesaid, whereby the matrices or type-plates of each set are released, as required; (*c*) two sets of keys, serving to control the two sets of matrices or type-plates aforesaid; (*d*) permutational selecting devices intermediate one set of keys at least and the releasing devices controlled thereby, whereby a few keys are made to control a large number of releasing devices, each as required; and (*e*) additional composing mechanism whereby the matrices or type-plates of the two sets released, are arranged in due order in a line; the whole being constructed, arranged and operating in such a manner that when keys of the two sets aforesaid are depressed by the operator simultaneously, thereby to free one matrix or type-plate of each set, the matrices or type-plates released belonging to the one set of matrices or type-plates, and controlled by the one set of keys are regularly assembled or disposed in advance, in the line, of the matrices or type-plates released from the other set of matrices or type-plates by the simultaneous acting of the operator upon the other set of keys.

26. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including in combination, (*a*) two sets of matrices or type-plates of the same case; (*b*) releasing devices for each set of matrices or type-plates; (*c*) two sets of keys; (*d*) quick-acting connections between the keys of one set and the releasing devices controlling one of the sets of matrices or type-plates before mentioned; (*e*) slow-acting connections between the keys of the other set and the releasing devices controlling the other set of matrices or type-plates before mentioned; the connections between at least one of the sets of keys before mentioned and the releasing devices controlled by them, being permutational selecting devices, whereby a few keys, acting singly and in different combinations are made to control a large number of releasing devices, each as required.

27. In a line-casting machine or other similar instrument, and in combination, (*a*) two sets of matrices or type-plates of the same case; (*b*) releasing devices for each set of matrices or type-plates aforesaid, whereby the different matrices or type-plates are released, as required; (*c*) a set of keys for the right hand; (*d*) permutational selecting devices intermediate the keys of the right hand and the releasing devices controlled thereby, whereby a few keys acting singly and in different combinations are made to control a large number of releasing devices, each as required; (*e*) a set of keys for the left hand; (*f*) permutational selecting devices, intermediate the keys of the left-hand set and the releasing devices controlled thereby, whereby a few keys are made to control a large number of releasing devices, each as required, and (*g*) means constructed to assemble the matrices or type-plates released from the two sets aforesaid in due order into a line.

28. In a line-casting machine, or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including in combination, (*a*) two sets of matrices or type-plates of the same case; (*b*) releasing devices for each set of

matrices or type-plates aforesaid, whereby the different matrices or type-plates are released, as required; (c) a set of keys for the right hand; (d) permutational escapement-selecting devices, intermediate the keys of the right hand and the releasing devices controlled thereby, whereby a few keys acting singly and in different combinations are made to control a large number of releasing devices, each as required; (e) a set of keys for the left hand; and (f) permutational escapement-selecting devices, intermediate the keys of the left-hand set and the releasing devices controlled thereby, whereby a few keys are made to control a large number of escapement devices, each as required; the connections between one set of keys and the releasing devices controlled thereby being quick-acting; and the connections between the other set of keys and the releasing devices controlled by them being slow-acting.

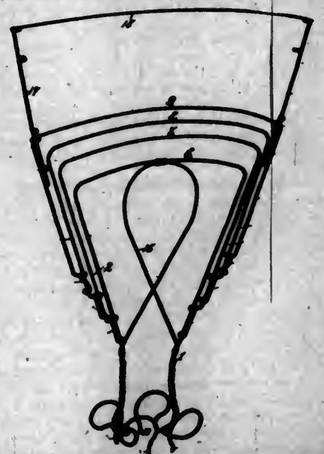
29. In a line-casting machine or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word simultaneously, and including (a) a set of lower-case matrices or type-plates; (b) storing devices for said matrices or type-plates, said storing devices being disposed in proximity to the line of matrices or type-plates being assembled; (c) another set of lower-case matrices or type-plates; and (d) storing devices for said last-mentioned matrices or type-plates, disposed more remote from the line of matrices or type-plates being assembled.

30. In a line-casting machine or other similar instrument, and in combination, (a) a set of lower case matrices or type-plates; (b) storing devices for said matrices or type-plates, said storing devices being disposed in proximity to the line of matrices or type-plates being assembled; (c) another set of lower-case matrices or type-plates of the same face; (d) storing devices for said last-mentioned matrices or type-plates, disposed more remote from the line of matrices or type-plates being assembled; and (e) composing mechanism constructed to assemble matrices or type-plates of the two sets aforesaid in due order into the same line.

31. In a line-casting machine or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word, simultaneously, and including (a) a set of lower-case matrices or type-plates; (b) storing devices for said matrices or type-plates, said storing devices being disposed in proximity to the line of matrices or type-plates being assembled; (c) another set of lower-case matrices or type-plates; (d) storing devices for said last-mentioned matrices or type-plates, disposed more remote from the line of matrices or type-plates being assembled; and (e) composing mechanism whereby the matrices or type-plates of the two sets aforesaid are arranged in due order in the line.

32. In a line-casting machine or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word simultaneously, and including (a) two sets of matrices or type-plates of the same case, to wit, a set of primary-letter matrices or type-plates and a set of secondary-letter matrices or type-plates; (b) releasing devices controlling the primary-letter matrices or type-plates aforesaid, said releasing devices being disposed in proximity to the line of matrices or type-plates being assembled; and (c) other releasing devices controlling the secondary-letter set of matrices or type-plates aforesaid; the last-mentioned releasing devices being disposed more remote from the line of matrices or type-plates being assembled than the releasing devices controlling the primary-letter set of matrices.

33. In a line-casting machine or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word simultaneously, and including (a) two sets of matrices or type-plates of the same case, to wit, a set of primary-letter matrices or type-plates and a set of secondary-letter matrices or type-plates; (b) releasing devices controlling the primary-letter matrices or type-plates aforesaid, said releasing devices being disposed in proximity to the line of matrices or type-plates being assembled; (c) other releasing devices controlling the secondary-letter set of matrices or type-plates aforesaid; the last-mentioned releasing devices being disposed more remote from the line of matrices or type-plates being assembled than the releasing devices controlling the primary-letter set of matrices; and (d) means whereby the matrices or type-plates released from the two sets aforesaid are arranged in due order in the line.



34. In a line-casting machine or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word simultaneously, and including (a) two sets of matrices or type-plates of the same case; (b) quick-acting selecting mechanism, controlling one set of said matrices, and (c) slow-acting selecting mechanism, controlling the other set of matrices aforesaid.

35. In a line-casting machine or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word simultaneously, and including (a) two sets of matrices or type-plates of the same case; (b) a quick-acting permutational selecting mechanism, controlling one set of said matrices or type-plates, and (c) a slow-acting permutational selecting mechanism, controlling the other set of said matrices or type-plates.

36. In a line-casting machine or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word simultaneously, and including (a) two sets of matrices or type-plates of the same case, one of said sets of matrices or type-plates being disposed in proximity to the line of matrices or type-plates being assembled, and the other of said sets of matrices or type-plates being disposed more remote from the line of matrices or type-plates being assembled; (b) quick-acting selecting mechanism controlling that set of matrices or type-plates before mentioned as being disposed in proximity to the line of matrices or type-plates being assembled, and (c) slow-acting selecting mechanism controlling the other set of matrices or type-plates aforesaid.

37. In a line-casting machine or other similar instrument, means constructed to afford facility to the operator to select a plurality of matrices or type-plates, corresponding to consecutive letters of a word simultaneously, and including (a) two sets of matrices or type-plates of the same case, one of said sets of matrices or type-plates being disposed in proximity to the line of matrices or type-plates being assembled, and the other of said sets of matrices or type-plates being disposed more remote from the line of matrices or type-plates being assembled; (b) quick-acting permutational selecting mechanism controlling that set of matrices or type-plates before mentioned as being disposed in proximity to the line of matrices or type-plates being assembled; and (c) slow-acting permutational selecting mechanism controlling the other set of matrices or type-plates aforesaid.

605,778. TRELLIS. FRED D. CLARK, Fruitsburg, N. Y. Filed May 22, 1897. Serial No. 637,782. (No model.)

Claim.—1. A trellis, consisting of a plurality of frames constructed to support a plant or vine and slidable vertically in operative connection with one another, for the purpose of lengthening, or shortening the trellis to increase or diminish its height, the lowermost frame having opposite arms provided at their lower ends with clutches to engage a flower-pot, substantially as and for the purpose described.

2. A trellis, consisting of a plurality of frames constructed to support a plant or vine and slidable vertically in operative connection with one another for increasing or diminishing the height of the trellis, the base or lower frame having opposite arms formed integral at their lower ends with spring-clutches for engaging a flower-pot or receptacle by which the trellis is supported upright, substantially as and for the purpose described.

3. A trellis, consisting of a plurality of wire frames, each having arms or members, the arms or members of the base or lower frame having spring-clutches to engage opposite sides of a flower-pot or receptacle and the arms or members of the other frames having sliding engagement with one another, for increasing or diminishing the height of the trellis, substantially as and for the purpose described.

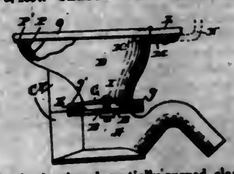
4. A trellis, consisting of a plurality of wire frames each composed of side arms or members connected at the top by a transverse member, the arms or members of the base or lower frame having spring clutches to engage opposite sides of a flower-pot or receptacle and the arms or members of the remaining frames having sliding engagement with one another, substantially as and for the purpose described.

5. A trellis, consisting of a plurality of wire frames, each composed of converging side arms or members and a transverse member, the base or lower frame having spring-clutches by which it may be supported upright and the remaining frames having their side arms or members provided with guide-eyes, so that said eyes of one frame may slide vertically upon the arms of another frame for increasing or diminishing the height of the trellis, substantially as and for the purpose described.

6. A trellis, consisting of a plurality of frames slidable longitudinally one upon another for increasing or diminishing the height of the trellis, and an extension-frame movably connected with the top portion of the uppermost slidable frame, substantially as and for the purpose described.

7. A trellis, consisting of a plurality of frames slidable longitudinally with relation to one another for increasing or diminishing the height of the trellis, the base or lower frame having clutches constructed to engage the bead or rib on the mouth of a flower-pot, substantially as and for the purpose described.

8. A trellis, consisting of a wire base or lower frame, and a plurality of upper frames, each composed of two arms connected by a transverse member, and the arms of each frame bent into eyes which engage and slide longitudinally on the arms of another frame, all of the frames being composed of wire, and the slidable frames mounted on the base or lower frame, substantially as and for the purpose described.

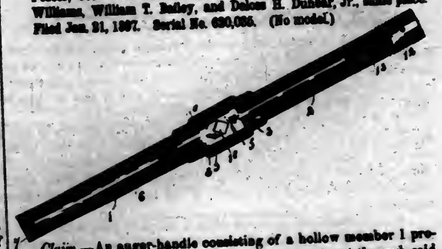


9. A trellis, consisting of a plurality of wire frames, each composed of two converging arms connected at the top by a transverse member, the arms of one frame having eyes sliding longitudinally on the arms of another frame for increasing or diminishing the height of the trellis, substantially as and for the purpose described.

605,779. BURGLAR-ALARM. WILLIAM U. COOPER, Shell Knob, Mo. Filed Sept. 16, 1897. Serial No. 651,861. (No model.)

Claim.—A burglar-alarm, comprising the bell 1 provided with the controlling-arm 2, the trip-lever 3 having its free end projecting into the path of the free end of said arm 2, the spring 4 connected to one side of said lever, and the cord 5 connected at one end to the opposite side of said lever and having its opposite end extending under tension over a fixed pulley 6 thence over a pulley 6' mounted on the movable bottom sash and its immediate end provided with a hook 9 adapted to be removably secured to the upper sash whereby a movement of either sash will slacken the cord to release the trip-lever 3 and sound an alarm, substantially as shown and described.

605,780. WATER-CLOSET. ALONZO W. CRAM, Haverhill, Mass. Filed June 5, 1897. Serial No. 639,594. (No model.)



Claim.—1. An improved partially-curved clamping device for the purpose described, consisting of the crescent-shaped plate formed with perforations at points backward from its ends, the plate being sprung upward slightly on a line intersecting the perforations, the back center of the plate and also its points thus depending in the manner and for the purpose herein shown and described.

2. The combination of a trap formed with projected ears, a bowl formed with a base peripheral flange, and a crescent-shaped clamping-plate adapted to embrace the bowl and rest on the flange, the plate being formed with perforated laterally-projecting ears at points backward from the ends of the clamping-plate, said ears aligning with

the trap-ears, the plate being sprung upward in the manner and for the purpose described, and the securing-screws, substantially as set forth.

3. An improved coupling for uniting flanged closet bowls and traps, including a yoke adapted to embrace one of said parts and rest on the flange thereof, said yoke being sprung between its ends so as to stand away from the flange, and securing means uniting with the spring portion of the yoke and adapted to compress the same toward the flange, substantially as shown and described.

605,781. AUGER-HANDLE. THOMAS A. GARNER, Bradford, Pa., assignor of one-half to Elmer E. Bryner, Samuel T. Boris, William Foster, Otto Peterson, Frank Morse, Phineo L. Billings, Agnes W. Williams, William T. Bailey, and Delcos H. Dunbar, Jr., same place. Filed Jan. 21, 1897. Serial No. 620,055. (No model.)

Claim.—An auger-handle consisting of a hollow member 1 provided with a head 3 at one end thereof, an opening 4 through said head to receive the end of a bit or auger, a rod 6 secured within the hollow member 1 and projecting beyond the inner end of the same, said rod 6 being provided with an opening 10 that is situated opposite the opening 4 in the head of the member 1 and having a screw-threaded outer end, a hollow member 2 provided at one end with a head 3 to fit within the head 3 of the member 1, the end of said head 3 of the member 2 being notched to engage the end of a bit or auger that is inserted within the opening 4, a nut 12 having a stem 13 situated within the outer end of the member 2 and having a shoulder bearing against the end of said member 2, said nut 12 being screw-threaded interiorly to receive the screw-threaded end of the rod 6.

605,782. PROPELLING MECHANISM FOR VESSELS. FRANK GRAY, Atlantic City, N. J. Filed May 14, 1897. Serial No. 636,581. (No model.)

Claim.—In a propelling mechanism for vessels, the combination of a cylinder closed at its inner end and open at its outer end, said end being exposed in an opening at the stern of the vessel, a steam-cylinder arranged in line with the water-cylinder, a piston-rod movable in axial line with said cylinders through stuffing-boxes in the adjacent heads thereof, a plunger upon the outer end of said movable

rod within the water-cylinder, a piston on the other end movable within the steam-cylinder, a steam-chest upon one end of the steam-cylinder having connection with the boiler, a sliding valve in said chest, a sliding valve controlling an exhaust-port on the opposite side of said cylinder and having connection with the condenser, connecting devices between the piston-rod and the valve-rods intermediate the two cylinders for automatically opening and closing said valves, and air and water supply pipes connected with the water-cylinder at the inner end thereof, all substantially as shown and described.

605,783. WOVEN FABRIC. ALFRED HEALD, Philadelphia, Pa. Filed Apr. 5, 1897. Serial No. 630,786. (Specimens.)

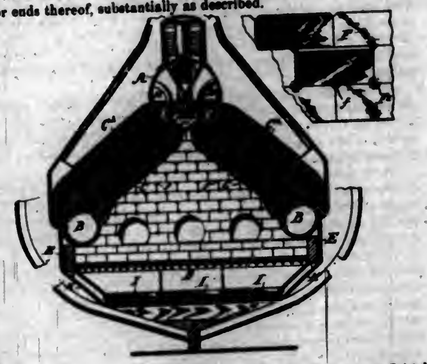
Claim.—1. A woven fabric in which damask warps, ingrain wefts, fine binding-warps, and a fine damask binding-weft are combined so as to form the face of the fabric in part of damask warps compressed and deeply indented by the fine binding-weft, and in part of ingrain wefts bound by the fine warps, substantially as specified.

2. A woven fabric in which damask warps, ingrain wefts in sets, fine binding-warps and a fine damask binding-weft are combined so as to form the face of the fabric in part of damask warps compressed and deeply indented by the fine binding-wefts and in part of ingrain wefts independently displayed and bound by the fine warps, substantially as specified.

3. A woven fabric in which damask warps, ingrain wefts in sets, ingrain binding-warps, and a fine damask binding-weft, are combined as described whereby the face of the fabric is composed in part of damask warps, compressed and deeply indented by the fine binding-weft, and in part of ingrain wefts independently displayed and bound by the fine warps, the ingrain wefts of each set lying side by side in the same horizontal plane on the back of the fabric where the damask warps appear upon the face, substantially as specified.

4. A woven fabric in which damask warps, ingrain wefts in sets, ingrain binding-warps, and a fine damask binding-weft, are combined as described whereby the face of the fabric is composed in part of damask warps compressed and deeply indented by said fine binding-weft, and in part of ingrain wefts independently displayed and bound by the fine warps, the ingrain wefts of each set being inserted in the same shed of binding-warp and said ingrain wefts lying side by side in the same place on the back of the fabric where the damask warps appear upon the face, substantially as specified.

5. A woven fabric comprising damask warps, ingrain wefts in sets, ingrain binding-warps, and a fine damask binding-weft, the face of the fabric being composed in part of damask warps compressed and deeply indented by the fine binding-weft, and in part of ingrain wefts independently displayed and bound by the fine warps, the damask warps lying between ingrain wefts upon the face of the fabric and ingrain wefts upon the back of the fabric wherever such damask warps do not appear upon the face, substantially as specified.



6. A woven fabric comprising damask warps, ingrain wefts in sets, ingrain binding-warps and a fine damask binding-weft, the face of the fabric being composed in part of damask warps compressed and deeply indented by the fine binding-weft, and in part of ingrain wefts independently displayed and bound by the fine warps, said ingrain wefts lying side by side in the same plane at the back of the fabric where the damask warps appear upon the face, and said damask warps lying between ingrain wefts on the face of the fabric and ingrain wefts upon the back of the same, wherever they do not appear upon the face, substantially as specified.

7. A woven fabric comprising damask warps, ingrain wefts comprising repetitions of two pairs with a like thread in each pair, ingrain binding-warps and a fine binding-weft combined as described whereby the face of the fabric is composed in part of damask warps compressed and deeply indented by the fine weft, and in part of the ingrain wefts independently displayed, said wefts lying side by side at the back of the fabric when the damask warps are on the face, and said damask warps lying between ingrain wefts of the face and back of the fabric wherever they do not appear upon the face, substantially as specified.

605,784. STEAM-BOILER. NATHANIEL G. HERRESHOFF, Bristol, R. I., assignor to the Herreshoff Manufacturing Company, same place. Filed Sept. 28, 1897. Serial No. 653,267. (No model.)

Claim.—1. In a steam-boiler, in combination with a central drum, side drums at a lower level, and a set of water-tubes between said central drum and each of said side drums, a fire-grate extended under said side drums so as to expose the same to the fire-gases, and baffle-plates arranged to concentrate the fire-gases at the lower portions of said water-tubes, substantially as described.

2. In a steam-boiler, in combination with a central drum, side drums at a lower level, and a set of water-tubes between said central drum and each of said side drums, a fire-grate extended under said side drums so as to expose the same to the fire-gases, and baffle-plates arranged between said water-tubes and extending downward from the said central drum so as to concentrate the fire-gases at the lower portions of said water-tubes while at the same time exposing said tubes to the fire-gases partly within the fire-chamber and partly within the flues outside said baffle-plates, said flues having their intakes at the lower ends and their gas-discharge openings at the upper ends thereof, substantially as described.

605,785. STEAM-BOILER. NATHANIEL G. HERRESHOFF, Bristol, R. I., assignor to the Herreshoff Manufacturing Company, same place. Filed Sept. 28, 1897. Serial No. 653,268. (No model.)

Claim.—1. In a dry-steam separator, a dome or inclosing casing, a deflector located at the base thereof, presenting an inclined passage to impart a helical movement to the ascending current of steam and leaving a circular clear space above said deflector, in combination with a foraminous screen K, in the interior near the periphery of the dome or casing, and against the inner face of which the steam is whirled in circulating contact, a lower water-discharge external to the screen, and a dry-steam-eduction pipe leading from the upper part of the dome or casing, substantially as herein specified.

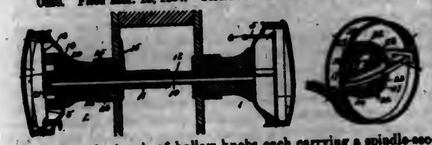
2. In a dry-steam separator, a dome or inclosing casing closed at the top, a deflector located at the base thereof, presenting an inclined passage to impart a helical movement to the ascending current of steam and leaving an annular clear space above said deflector, in combination with a foraminous screen K extending around in the interior near the periphery, a lower water-discharge external to the screen, and a dry-steam-eduction pipe leading downward from the upper part of the dome or casing in the axis thereof, substantially as herein specified.

3. In combination with a steam-boiler having a water-surface insufficient for the proper disengagement of the steam, the dome A' extending upward from the body of the boiler, the steam-pipe J extending downward from near the top in the center of the dome, a foraminous screen K in the interior near the periphery of the dome leaving an annular space exterior thereto, a pipe L leading downward from such exterior space to a point below the water-level in the boiler, and a series of inclined deflectors P arranged in the bottom of the annular space between such screen and the central pipe leaving the upper portion of such space clear, adapted to impart a helical motion to a large quantity of steam ascending therethrough while requiring little vertical height in the series, all arranged for joint operation substantially as herein specified.

4. In combination with a steam-boiler having a water-surface insufficient for the proper disengagement of the steam, the dome A' extending upward from the body of the boiler, a pipe J extending downward in the center, the foraminous screen K in the interior near the periphery of the dome, leaving an annular space exterior thereto, the pipe L leading downward from such exterior space to a point below the water-level in the boiler, and a substantially annular series of inclined deflectors P arranged in the base of the dome between such screen and the central pipe, adapted to impart a helical motion to the steam ascending therethrough leaving an unobstructed space above such deflectors in which the particles of water may freely move tangentially to reach the screen, all substantially as herein specified.

5. In a steam-boiler, a dome A' covering a portion of the drum or body A outside of the aperture for such dome and a foraminous screen K extending around within the dome and joined to the body at the edge of the aperture, in combination with a series of inclined deflectors P arranged to cause the steam rising through it to travel helically in a clear space above so that the inclosing foraminous screen shall receive the particles of water and allow them to move outward through it and descend in a quiet space outside thereof, and one or more pipes L communicating between such quiet space and a point in the body or drum below the water-line, such pipes being set in the portion of the boiler-shell within the dome, all substantially as herein specified.

605,786. STEAM-BOILER. NATHANIEL G. HERRESHOFF, Bristol, R. I., assignor to the Herreshoff Manufacturing Company, same place. Original application filed Sept. 28, 1897, Serial No. 653,268. Divided and this application filed Jan. 11, 1898. Serial No. 666,307. (No model.)



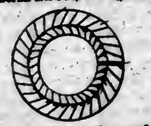
Claim.—1. In a steam-boiler having a central drum A and lower side drums B with connections C C, the front and rear walls F containing fire-bricks having their corners beveled, in combination with an exterior shell of metal F' and with a continuous intermediate air-space in free communication with the ash-pit, arranged to serve substantially as herein specified.

2. In a steam-boiler having a central drum A and lower side drums B, with connections C C, the front and rear walls F containing fire-bricks provided with recesses f' in their mid-thickness, in combination with an exterior shell F' of metal held at a little distance outside of such bricks, bolts F^2 having their heads and the adjacent portions of the shanks recessed into the bricks of the wall, and their opposite ends adjustably secured in the metallic shell, and adjusting-nuts F^3, F^4, all arranged to serve substantially as herein specified.

3. In a steam-boiler furnace a brick wall F having bricks formed and matched together so as to provide air-spaces f at the angles, a continuous metallic shell F' exterior to such wall, and standing at a sufficient distance therefrom to provide an intermediate air-space connecting the several apertures in the brick wall with the ash-pit, a series of holding-bolts F^2 having their heads and adjacent portions engaged with the brick wall and their opposite ends engaged with the metallic shell, and adjusting-nuts F^3, F^4, all combined and arranged to serve substantially as herein specified.

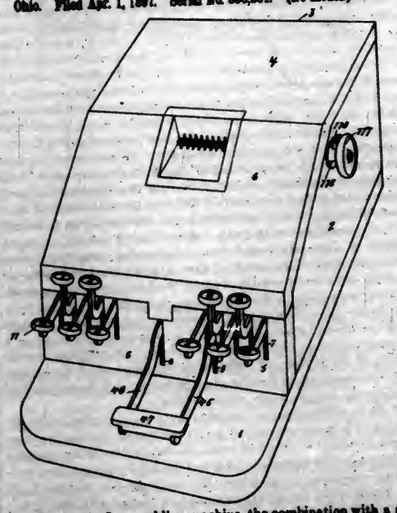
4. In a steam-boiler ash-pit, the damper Q, of arched form adapted to automatically open by the incoming air and assume a horizontal position within a recess provided, and close and resist archwise any back pressure of the gases, combined and arranged to serve substantially as herein specified.

605,787. COMBINATION-LOCK. CHARLES F. HILL, Middle Branch, Ohio. Filed Mar. 13, 1897. Serial No. 627,294. (No model.)



Claim.—1. A pair of hollow knobs each carrying a spindle-section, one of which is tubular, in combination with levers mounted in said knobs, a connection between said levers for simultaneously operating them, and locking mechanism arranged in one of the knobs and adapted to be engaged by one of said levers, substantially as and for the purpose specified.

2. Two hollow knobs, each having spindle-sections, one of which is tubular, in combination with levers arranged one in each knob, a connection between said levers for simultaneously operating them, means projecting exteriorly of one of the knobs for operating one of the levers, and locking mechanism in the other knob adapted to be engaged by the lever therein, substantially as and for the purpose described.



3. The combination with a hollow door-knob, of a plurality of rotatable tumblers mounted therein and notched, a lever mounted in said knob for engagement with the notches in the tumblers, a spring for giving said lever a normal tendency, and an operating connection for said lever extending through the knob-spindle and adapted to be operated from the opposite knob, substantially as described.

605,788. NUT-LOCK. FRANK O. JOHNSON, North Clarendon, Pa. Filed July 12, 1897. Serial No. 644,264. (No model.)

Claim.—As an improved article of manufacture, a nut-lock of the type comprising a split spiral ring or washer formed upon its opposite faces with ratchet-teeth of angular shape extending in opposite directions from the central line of said ring, with the meeting-point of said teeth upon one face of the nut-lock elevated and those upon the opposite side depressed, all substantially as and for the purpose specified.

605,789. ADDING-MACHINE. ROBERT H. KINBALL, Cleveland, Ohio. Filed Apr. 1, 1897. Serial No. 630,231. (No model.)

Claim.—1. In an adding-machine, the combination with a series of operating-keys, of a carriage mounted for reciprocation, intermediate connections between the keys and carriage, whereby the latter is moved forwardly upon the depression of any of the keys, spring-actuated mechanism for automatically returning the carriage to its initial position, a series of numeral-pinions arranged upon the shaft for independent rotation, a pinion-actuating device mounted upon the carriage, and an intermittent lateral feed for said device, adapted to throw the latter in engagement with one of the pinions before the forward movement of the carriage, and out of engagement with the pinion upon the return movement of the carriage.

2. In an adding-machine, the combination with a series of operating-keys, of a carriage mounted for reciprocation, intermediate connections between the keys and carriage, whereby the latter is moved forwardly upon the depression of any of the keys, spring-actuated mechanism for automatically returning the carriage to its initial position, a series of numeral-pinions arranged upon a shaft for independent rotation, a pinion-actuating device mounted upon the carriage, and an intermittent lateral feed for said device, adapted to throw the latter in engagement with one of the pinions before the forward movement of the carriage, and between said pinion and the next successive pinion before the return movement of the carriage.

3. In an adding-machine, the combination with a series of oper-

ating-keys, of a longitudinally-reciprocating carriage, a series of numeral-pinions arranged for independent rotation, a carriage-driving mechanism connecting the keys with the carriage, and adapted upon depression of any one of said keys to drive the carriage forward beneath the series of pinions to rotate one of the latter, spring-actuated mechanism for automatically returning the carriage to its initial position, a pinion-operating device upon the carriage, and lateral shifting mechanism for said device.

4. In an adding-machine, the combination with a series of operating-keys, of a carriage mounted for horizontal reciprocation, intermediate connections between the keys and carriage, whereby the latter is moved forwardly upon the depression of any of the keys, spring-actuated mechanism for automatically returning the carriage to its initial position, a series of numeral-pinions arranged upon a shaft for independent rotation, a rack upon the carriage adapted to engage with and rotate one of the pinions during the forward movement of said carriage, and lateral intermittent feed mechanism for moving the rack out of engagement with one pinion and in engagement with its next successive pinion, comprising an escapement 42 upon which the rack is secured, an escapement-key 44, and intermediate connections between the operating-keys and said escapement-key, and between the carriage-returning mechanism and the escapement-key, whereby the escapement is given an intermittent lateral movement.

5. In an adding-machine, the combination with a pinion-operating carriage mounted for horizontal reciprocation, and the driving mechanism for moving said carriage forwardly, comprising a series of operating-keys, lever 13, arm 37, a gear connection between the arm and lever, carriage-arm 28, and pin 41, substantially as described.

6. In an adding-machine, the combination with a pinion-operating carriage mounted for horizontal reciprocation, and the mechanism for reciprocating said carriage, comprising a series of operating-keys, a spring-actuated toothed lever 13, lever-arm 37, segment-gear 38, carriage-arm 28, and connecting-pin 41, substantially as described.

7. In an adding-machine, the combination with a carriage mounted for horizontal reciprocation, of a series of numeral-pinions sleeved upon a shaft for independent rotation, a pinion-operating rack mounted upon the carriage, and mechanism for feeding said rack laterally, and for operating the pinions successively comprising a series of operating-keys, the spring-actuated lever 13, lever-arm 37, a gear connection between levers 13 and 37, the slotted carriage-arm 28, an escapement-key slidingly supported beneath the escapement, carrying a pin 41 engaging the lever 37 and arm 28 and a stud 53 upon the key extending within said escapement, substantially as described.

8. In an adding-machine, the combination with a series of operating-keys, of a carriage mounted for reciprocation, intermediate connections between the keys and carriage whereby the latter is moved forwardly upon the depression of any of the keys, a series of numeral-pinions arranged upon a shaft for independent rotation, a pinion-actuating device upon the carriage adapted to engage with and rotate one of the pinions during the forward movement of the carriage, a stop mechanism adapted to limit the travel of the carriage, and the rotation of the pinion, and spring-actuated mechanism for moving the pinion-actuating device out of engagement with the pinion, and returning the carriage to its initial position.

9. In an adding-machine, the combination with a series of operating-keys, of a carriage mounted for reciprocation, intermediate connections between the keys and carriage, whereby the latter is moved forwardly upon the depression of any of the keys, a series of numeral-pinions arranged upon a shaft for independent rotation, a pinion-actuating device upon the carriage adapted to engage with and rotate one of the pinions during the forward movement of said carriage, and stop mechanism for limiting the travel of said carriage and the rotation of the pinion, comprising a single series of stop-bars having intermediate connections with the keys, whereby, upon the depression of any key, its corresponding stop-bar will be thrown in the path of the advancing carriage.

10. In an adding-machine, the combination with a series of operating-keys, of a carriage mounted for reciprocation, intermediate connections between the keys and carriage, whereby the latter is moved forwardly upon the depression of any of the keys, a series of numeral-pinions arranged upon a shaft for independent rotation, a pinion-actuating device upon the carriage, adapted to engage with and rotate one of the pinions during the forward movement of the carriage, and stop mechanism for limiting the travel of the carriage, comprising a series of bars resting and the rotation of the pinion, normally upon the keys, substantially as described.

11. In an adding-machine, the combination with a series of operating-keys, of a carriage mounted for reciprocation, intermediate connections between the keys and carriage whereby the latter is moved forwardly upon the depression of any of the keys, a series of numeral-pinions arranged upon a shaft for independent rotation, a pinion-actuating device upon the carriage, adapted to engage with and rotate one of the pinions during the forward movement of the carriage, and a stop mechanism for limiting the travel of the carriage, and the rotation of the pinion, comprising a series of bars resting normally upon the keys, and a series of spring-clips connecting each bar with its key, whereby, upon the depression of the latter, the bar will be drawn downwardly in the path of the carriage.

12. In an adding-machine, the combination with a series of operating-keys, of a carriage mounted for reciprocation, intermediate connections between the keys and carriage whereby the latter is moved forward upon the depression of any of the keys, a series of numeral-pinions arranged upon a shaft for independent rotation, a pinion-actuating device upon the carriage adapted to engage with and rotate one of the pinions during the forward movement of said carriage, and a stop mechanism for limiting the travel of the carriage and the rotation of the pinion, comprising a series of bars, provided with depending fingers, adapted to rest upon the keys, and a projecting arm 56, said arm being provided with a longitudinal slot, in which a portion of the carriage is adapted to travel, and with a series of transverse slots in which the bars are drawn upon the depression of the keys, substantially as described.

13. In an adding-machine, the combination with a reciprocating carriage, a series of numeral-pinions, a rack and a lateral feed therefor mounted upon the carriage, actuating mechanism for operating said carriage and feed, a carrying-key, a rack-returning device having intermediate connections with the key, whereby the said device is moved in one direction upon the depression of the key, and means for automatically returning the device and rack to their initial positions upon the releasement of the key.

14. In an adding-machine, the combination with a reciprocating carriage, a series of pinions, a rack and a lateral feed therefor mounted upon the carriage, actuating mechanism for operating the carriage and feed, a carrying-key, a rack-returning frame having intermediate connections with the key whereby, upon the depression of the latter, the frame is moved in one direction, and means for automatically returning the frame and rack to their initial positions upon the releasement of the key.

15. In an adding-machine, the combination with the carriage, the numeral-pinions, a rack, and a lateral feed therefor, arranged upon the carriage, actuating mechanism for operating the carriage and feed, and means for returning the rack, after its lateral travel, to its initial position, comprising a carrying-key, a frame mounted for reciprocation, a latch upon said frame, intermediate connections between the frame and key, whereby, upon the depression of the latter, the frame is moved in one direction, and a spring for automatically returning the frame and rack to their initial positions upon the releasement of the key.

16. In an adding-machine, the combination with the carriage, the numeral-pinions, a rack, and a lateral feed therefor, arranged upon the carriage, actuating mechanism for operating the carriage and feed, and means for returning the rack, after its lateral travel, to its initial position, comprising the carrying-key provided with a lever-arm 46, a projecting piece 53 carried on said arm, the carrying-frame, the latch thereon, lever 90, strap 95, and a spring 98, substantially as described.

17. In an adding-machine, the combination with a carriage, a series of numeral-pinions, and actuating mechanism for reciprocating the carriage and rotating the pinions, a series of carrying pawl-levers arranged in proximity to the pinions, carrying-pawls upon said levers engaging the pinions, a cam mechanism in connection with each pinion, adapted, at certain periods, to throw back the carrying-levers, a reciprocating frame, and a carrying device arranged thereon, adapted, during the reciprocation of said frame, to return the carrying-levers to their initial position.

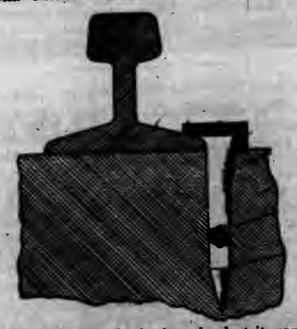
18. In an adding-machine, the combination with a carriage, a series of numeral-pinions, and actuating mechanism for reciprocating the carriage and rotating the pinions, a series of carrying pawl-levers arranged in proximity to the pinions, carrying-pawls upon said levers engaging the pinions, and cam mechanism in connection with each pinion, adapted, at certain periods, to throw back the carrying-levers, a reciprocating frame, and an inclined face thereon, adapted, during the reciprocation of the frame, to return the carrying-levers to their initial positions.

19. In an adding-machine, the combination with the carriage, a series of numeral-pinions, and actuating mechanism for reciprocating the carriage and rotating the pinions, a series of carrying pawl-levers arranged in proximity to the pinions, carrying-pawls upon said levers engaging the pinions, a cam mechanism in connection with each pinion, adapted, at certain periods, to throw back the carrying-levers, a reciprocating frame, an inclined face thereon, adapted, during the reciprocation of the frame, to operate the pawl-levers, and a shoulder on said frame opposite the inclined face adapted to engage with the pinions, substantially as described.

20. In an adding-machine, the combination with a series of numeral-pinions, a reciprocating carriage for rotating the pinions a series of carriage-operating keys, and differential stops controlled by the keys for limiting the travel of the carriage.

21. In an adding-machine, the combination with a series of numeral-pinions, a reciprocating carriage, a series of carriage-operating keys, differential stops controlled by the keys for limiting the travel of the carriage, a pinion-actuating device upon said carriage, and a shifting mechanism for moving said pinion-actuating device laterally.

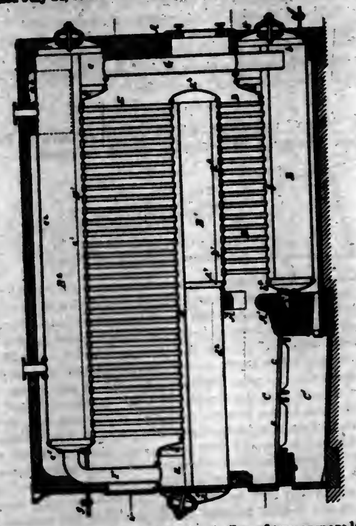
22. In an adding-machine, the combination with a series of operating-keys, of a carriage mounted for reciprocation, intermediate connections between the keys and carriage, whereby the latter is moved forwardly upon the depression of any of the keys, spring-actuated mechanism for automatically returning the carriage to its initial position, a series of numeral-pinions arranged upon a shaft for independent rotation, a rack mounted upon the carriage, a lateral feed for said rack adapted to throw the latter in engagement with one of the pinions before the forward movement of the carriage, and a safety device for preventing said forward movement of the carriage until the rack is in engagement with one of the pinions.



23. In an adding-machine, the combination with a series of operating-keys, of a carriage mounted for reciprocation, intermediate connections between the keys and carriage, whereby the latter is moved forwardly upon the depression of any of the keys, spring-actuated mechanism for automatically returning the carriage to its initial position, a series of numeral-pinions arranged upon a shaft for independent rotation, a rack mounted upon the carriage, and a lateral feed for said rack adapted to throw the latter in engagement with one of the pinions before the forward movement of the carriage, and a safety device for the purpose of preventing the forward movement of said carriage until the rack is in engagement with one of the pinions, said device consisting of the toothed bar 69 swingingly supported from the casing, and located as described.

24. In an adding-machine, the combination with a series of numeral-pinions, a reciprocating carriage for rotating said pinions, and a carrying mechanism for the pinions adapted to rotate such of the latter as are involved in the operation of carrying, comprising a series of pinion-rotating devices, a cam mechanism in connection with each pinion for moving its rotating device outwardly, and a reciprocating frame for returning each rotating device to its initial position.

25. In an adding-machine, the combination with a series of numeral-pinions, operating-keys therefor, and a carrying mechanism comprising devices for rotating said pinions, and means independent of said pinions and actuated by said keys for actuating said devices.



26. In an adding-machine, the combination with a plurality of numeral-pinions mounted for independent rotation in one direction, a series of carrying-levers arranged in proximity to the pinions and having intermediate connections with the latter, an independent automatically-reciprocated frame for operating said carrying-levers and a pinion-operating device for completing, without moving the carrying-levers, the revolutions of all the pinions left partially rotated after the operation of adding has been completed.

605,790. RAIL-ROAD-SPIKE. JAMES H. MALVIN, Arkansas Junction, Colo. Filed Mar. 19, 1897. Serial No. 628,264. (No model.)

Claim.—A railroad-spike having a head at its upper end, with a side flange thereon, a shoulder located just beneath said head on the edge opposite said flange having an angularly-arranged flat surface, a shank which is rectangular in cross-section throughout its entire length, and with an angularly-arranged reinforcing portion extending entirely across said shank having a flat surface and located just beneath said shoulder, and an arrow-shaped lower end formed by triangular converging faces which terminate in a point and separated from the shank of the spike by shoulders formed by angularly-arranged notches extending entirely across said shank, the outer edges of said shoulders lying in the same plane with the sides of the shank.

605,791. STEAM-BOILER. EDWARD J. MOORE, Philadelphia, Pa. Filed July 31, 1897. Serial No. 645,622. (No model.)

Claim.—1. The combination in a boiler, of two or more longitudinal water-drums one mounted above another, water-tubes connecting the drums, the lower drum being short with a fire-chamber in advance of said lower drum, substantially as described.

2. The combination in a boiler, of three longitudinal drums, one mounted above another, vertical tubes connecting the central drum with the top and bottom drums, the bottom drum being short, with a fire-chamber in front of the bottom drum, substantially as described.

3. The combination in a boiler, of three drums, tubes connecting the central drum with the top and bottom drums, a fire-chamber in advance of the bottom drum, the central drum terminating short of the top and bottom drums so as to allow for the passage of the products of combustion around the end of the central drum, substantially as described.

4. A steam-boiler drum semicircular in cross-section and having a tube-plate on its flat side, and a short circular section at one end, substantially as described.

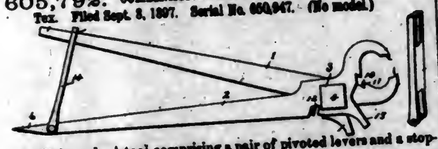
5. A steam-boiler drum semicircular in cross-section and having a tube-plate on its flat side, and a short circular section at one end, with dished head at each end, substantially as described.

6. A steam-boiler drum having one portion semicircular in cross-section, the circle extending beyond the center and having a flat tube-plate coupling the two edges of the semicircular portion, substantially as described.

7. A drum for a boiler having a long tube sheet extending nearly the full length of the drum, and a short tube-sheet connected to the long tube-sheet at one end by curved side plates, and a semicircular section coupled to the other end of the long tube-sheet and secured to the short tube-sheet by a gusset-plate, substantially as described.

8. A gusset for a steam-boiler in the shape of a crescent having a flange extending in one direction from the upper portion of the gusset and a flange extending in the opposite direction from the opposite portion of the gusset, said flanges being attached to the boiler-plates, substantially as described.

9. The combination in a steam-boiler, of three drums, tubes connecting the central drum with the upper section and with the lower section, with a fire-chamber in advance of the lower drum, the portion of the central drum above the fire-chamber being semicircular in cross-section, substantially as described.



10. The combination in a steam-boiler, of three longitudinal drums, the fire-chamber, circulating-tubes extending from the lower drum to the middle drum and from the middle drum to the upper drum, a tube forming communication between the forward end of the central drum and the upper drum and a tube forming communication between the rear end of the upper drum and the rear end of the lower drum, substantially as described.

11. The combination of three drums arranged one above another, vertical circulating-tubes connecting the central drum to the upper and lower drums, with a series of vertical deflecting-plates arranged between the upper and the central drums whereby the products of

combustion will pass between the tubes in a serpentine path, substantially as described.

12. The combination in a steam-boiler, of the fire-chamber, its bridge-wall, a drum back of the bridge-wall, a drum over the fire-chamber and the first-mentioned drum, vertical tubes extending from one drum to the other, an arch directly over the bridge-wall, and an upper drum with vertical tubes extending from the central drum to the upper drum, substantially as described.

605,792. COMBINATION-TOOL. WILLIAM H. MCCARTY, Hanbot, Tex. Filed Sept. 8, 1897. Serial No. 650,947. (No model.)

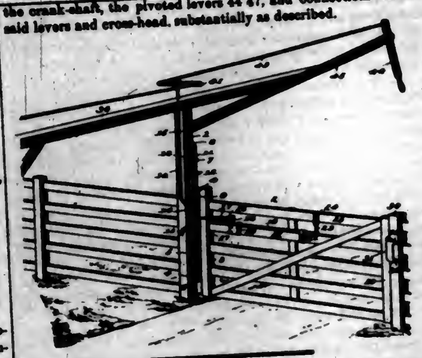
Claim.—1. A tool comprising a pair of pivoted levers and a stop-link pivoted to one of said levers and provided with a slot or opening in its free end, through which passes the other of said levers, the outer end of the said stop-link being free to move upon the arc of a circle, with the pivotal point of said link as a center, whereby the end of the lever which passes through the slot therein may be positively adjusted at any point relative to the other of said levers.

2. A wire-twisting tool comprising a pair of levers pivoted one to the other and having laterally-extending overlapping twisting-fingers thereon, the said twisting-fingers being formed integral respectively with said levers and lying in the same plane therewith, and means for adjusting the relative positions of said twisting-fingers.

3. A tool of the character described, comprising a pair of pivoted levers having jaws formed upon their forward ends, having twisting-fingers located adjacent to the said jaws and adapted to coact one with the other, the said fingers extending laterally of said levers, formed integral therewith and lying in the same plane therewith, and a locking-link pivoted at one end to one of said levers and having a slot or opening in its opposite end, through which the other of said levers is adapted to pass, the free end of said link being capable of movement upon the arc of a circle, with its pivotal point as a center, whereby said levers and the twisting-fingers attached thereto may be positively adjusted relatively, one to the other.

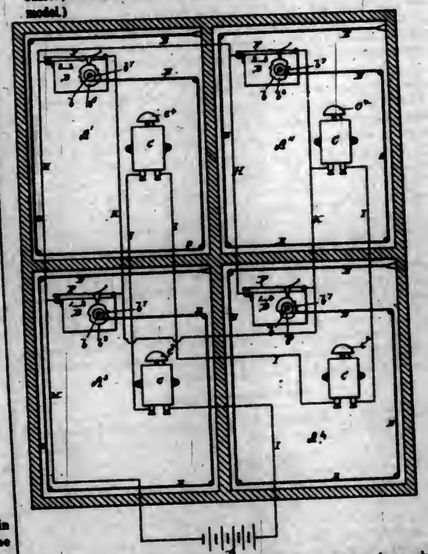
605,793. RAIL-HOLDER. CHARLES MCLENNON, Spring Gulch, Colo. Filed Jan. 29, 1898. Serial No. 668,468. (No model.)

Claim.—1. A rail-chair made from a flat plate, having a seat in one edge thereof, and having legs extending laterally in the same direction from opposite ends of opposite sides of the plate.



2. A rail-chair composed of a flat plate provided with legs extending laterally in the same direction from the opposite ends of the opposite sides of the plate, and with an intermediate longitudinally-disposed beak located above the upper edge of the plate and defining one side of the rail-seat, substantially as specified.

3. A rail-chair, composed of a flat plate provided with a chair-seat and with inclined notched ends, substantially as specified.

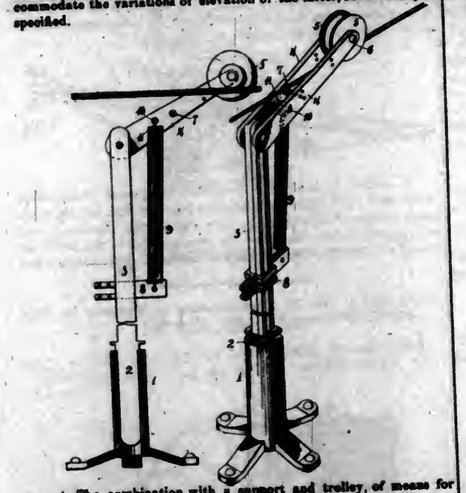


4. A rail-chair composed of a flat plate provided with laterally-extending legs located at the opposite ends of its opposite sides, a longitudinally-disposed beak located at the front end of its upper side, and defining one side of a chair-seat, the plate being provided with parallel inclined end walls having notches for the reception of spikes, substantially as specified.

605,794. GATE. FRANCIS F. MCMULLEN, Bondville, Ill. Filed July 15, 1897. Serial No. 644,700. (No model.)

Claim.—In a gate, the combination with the hinging-post 1 and the keeper-post 30, of the gate 2 hinged to the former and provided with the reciprocating latch-rail 22 to engage the latter, the crank-shaft 15 journaled in bearing-brackets on the hinging-post, the latch-rod 19 mounted in the brackets 20 21 on the latch-rail and pivoted at its front end to the connecting-rod 23, the rod 17 connecting the rear end of the latch-rod and crank-arm 16 of the crank-shaft, the spring 26 bearing against said bracket 20, the cross-head 41 fixed to the crank-shaft, the pivoted levers 44 47, and connections between said levers and cross-head, substantially as described.

605,795. AUTOMATIC ELECTRIC FIRE-ALARM. HERMAN A. CLARKE, Quincy, Mass. Filed June 17, 1897. Serial No. 641,135. (No model.)



Claim.—In an automatic-electric-fire-alarm system in combination, an electric current generator, a series of current-interrupters and alarms electrically connected to the current-generator one in each room of the building, each such current-interrupter having a spring-actuated circuit breaking and closing disk differing from the others in the series and a fusible cord or wire for normally holding each disk stationary and to cause it to be released when said cord or wire is ignited or fused by which the circuit is alternately closed and opened to cause an alarm corresponding to the number of the room in which the fire occurs to be automatically sounded in all the other rooms in the circuit substantially as and for the purpose set forth.

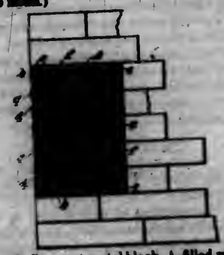
605,796. TROLLEY-POLE. JOHN H. PERM, Johnstown, Pa. Filed Feb. 8, 1897. Serial No. 622,456. (Model.)

Claim.—1. The combination with a suitable support and trolley, of means for retaining the trolley in contact with the wire either from above or from below, substantially as specified.

2. The combination with a suitable support and trolley, of mechanism for retaining the trolley in contact with the wire from above under pressure, and means for automatically dropping the trolley below the wire and for urging it against the under side of said wire, substantially as specified.

3. The combination with a support and trolley, of means for automatically shifting said trolley above and below the wire to accommodate the variations of elevation of the latter, substantially as specified.

4. The combination with a support and trolley, of means for shifting said trolley both above and below the wire, and for retaining it in contact with said wire from above or below under pressure, substantially as specified.

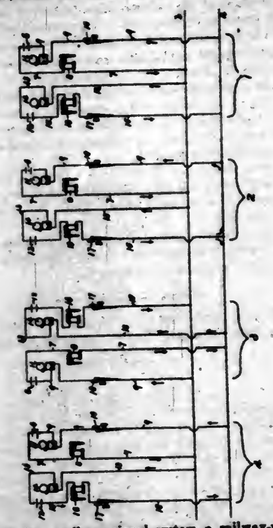


5. In a trolley-pole, two pivoted arms, a trolley-wheel consisting of two independent disks adapted to normally abut against each other, and means to hold said disks in connection, whereby the said wheels may be separated so as to be positioned above the conductor-wire, substantially as shown.

6. In a trolley-pole, a swivel-post, arms pivoted thereto, consisting of two separable sections, a spring for holding said sections normally in contact, and a spring bearing against the arms to lift the same whereby the said sections of the trolley-wheel may be separated to enable said wheel to take position above the conductor-wire, substantially as described.

7. In a trolley-pole, a socket having a swiveled post, an adjustable bracket upon said post, swinging arms secured to said post, and a spring bearing against a plate carried by said arms and against said bracket.

8. In a trolley-pole, the combination of a swivel-post, two arms pivoted thereto and extending parallel to each other, a trolley-wheel consisting of two separable disks one rotatably mounted on each arm, a spring engaging said arms to normally hold the disks in contact, a bracket on the swivel-post, and a spring connecting between the said bracket and the arms to lift the latter, substantially as described.



605,797. INDESTRUCTIBLE BLOCK FOR BOILER-FURNACES. JAMES REAGAN, Philadelphia, Pa. Filed Sept. 7, 1897. Serial No. 650,811. (No model.)

Claim.—1. A hollow cast-metal block, A, filled with ashes or other non-conductors of heat, and provided on one side or top with an opening and sliding lid E, and on the opposite side with a series of inclined ribs or projections *c c*, to form ledges and grooves or channels for the retention of ashes, substantially as and for the purpose specified.

2. The hollow block, A, packed with ashes or other suitable material, provided with ribs *c c*, and grooves or channels *d d*, inclining inwardly, and chipping strips *e e*, in combination with the side walls of a boiler-furnace, substantially as shown and described.

605,798. ELECTRIC RAILWAY-SIGNAL. CHARLES I. REDREW, East Windsor, Conn. Filed Mar. 2, 1897. Serial No. 625,711. (No model.)

Claim.—1. In a railway signal system, a railway-vehicle provided with two branch circuits, each containing a generator and an indicating device, the branches being connected into complete circuit with the generators in series through the conductors, and the indicating devices requiring more current to operate them than is generated by the generators, substantially as described.

2. In a railway signal system, a railway-vehicle provided with two branch circuits, each containing a generator and an indicating device, the branches being connected into complete circuit with the generators in series through the conductors, and the indicating devices requiring more current to operate them than is generated by the generators, and a circuit-breaker for cutting out one of said generators substantially as described.

3. In a railway signal system, the combination of two conductors suitably insulated, of a railway-vehicle, two generators on said vehicle, connections from each of said generators to said conductors arranged to connect said generators in series through said conductors, an indicator connected with each of said generators, and an auxiliary indicator connected with each of said generators, said auxiliary indicators requiring more current to operate the same than is required to operate the other indicators, substantially as described.

4. In a railway signal system, the combination with two conductors suitably insulated, a railway-vehicle, two electric generators on said vehicle, connections from each of said generators to said conductors arranged to connect said generators in series through said conductors, an indicator connected with each of said generators, and a circuit-breaker for cutting out one of said generators, substantially as described.

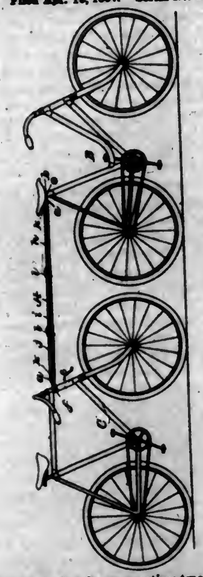
5. In a railway signal system, the combination with two conductors suitably insulated, a railway-vehicle, two electric generators on said vehicle, connections from each of said generators to said conductors arranged to connect said generators in series through said conductors, an indicator connected with each of said generators, and circuit-breakers for cutting out either of said generators, substantially as described.

6. In a railway signal system, a railway-vehicle, two generators on said vehicle, conductors leading from each of said generators and arranged for connection with stationary conductors, an indicator in the conductors leading from each of said generators comprising an electromagnet and its armature, and a single spring connected to the armature of both magnets, substantially as described.

7. A circuit-breaker comprising a movable member, two conducting-surfaces on said movable member insulated from each other, a non-conducting surface adjacent each conducting-surface and out of line with each other, brushes bearing on each of said conducting-surfaces out of the path of said non-conducting surface, and brushes bearing on said conducting-surfaces and in the path of said non-conducting surfaces, substantially as described.

8. In a railway-signal system, the combination of a bracket, a support for a conductor mounted thereon, an arm extending from

said bracket, a stationary jaw on said arm, guides on said arm, a movable jaw on said guides, and a bolt for forcing said movable jaw against the base of the railway-rail, substantially as described.



9. In a railway signal system, a support for a conductor, a bracket, means securing said bracket to the railway-rail, insulating material between the support and bracket, and a water-guard above said insulating material, substantially as described.

10. In a railway signal system, a bracket, means for securing said bracket to the railway-rail, a support for a conductor provided with a stud passing through said bracket, insulating material between said stud and bracket, and a water-guard above said insulating material, substantially as described.

11. In a railway signal system, a conductor, a trolley for engaging said conductor, and means comprising a V-shaped recess and a stud for centering said trolley when it leaves the conductor, substantially as described.

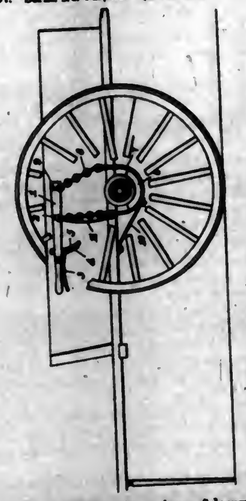
12. In a railway signal system, a slide, a trolley carried by said slide, an inverted-V-shaped recess in said slide, and a pin projecting into said recess, substantially as described.

605,799. COUPLING FOR BICYCLES. PRESTON T. RIPLEY, Cambridge, Mass. Filed Apr. 19, 1897. Serial No. 632,861. (No model.)

Claim.—1. A coupling for connecting two bicycles (one forward of the other), formed of parts and having universal joints at its ends, one of said parts being provided with means for securing it to the frame of one bicycle, and another of said parts provided with a tubular portion to enter upon the seat-post of the other bicycle, substantially as set forth.

2. In a coupling for connecting two bicycles, one forward of the other, the combination of several tubes, one to slide within another, a clasp and pin to maintain the tubes in suitable relation to each other when extended, a piece connected with one of said tubes by a ball-and-socket joint and provided with a tubular part to enter upon the seat-post, a piece connected with another of said tubes by a ball-and-socket joint and provided with a clasp to encircle the steering-head, and means as a strap for retaining said tubular part on the seat-post, substantially as specified.

605,800. BRAKE-BEAM. HENRY B. ROSENBURG, Kalamazoo, Mich., assignor to the Chicago Railway Equipment Company, Chicago, Ill. Filed July 23, 1896. Serial No. 600,126. (No model.)



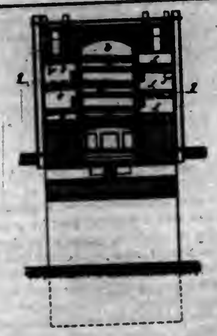
Claim.—1. In a trussed brake-beam the combination with a post or strut and tension-rod, of a longitudinally-slotted tubular compression member having the slot edges in opposition except at the points where the tension-rod enters the compression member; substantially as and for the purposes specified.

2. In a trussed brake-beam, having a strut or post and a tension-rod, the combination therewith of a high-carbon longitudinally-slotted tubular compression member, the slot edges thereof in apposition except where the tension-rod enters the compression member; substantially as and for the purposes specified.

3. A blank for making the compression members of trussed brake-beams, said blank having parallel sides provided with notches at opposite points and adjacent to its ends, whereby the notches thereof will register to form slots when the parallel edges of the blank are brought in apposition; substantially as and for the purposes specified.

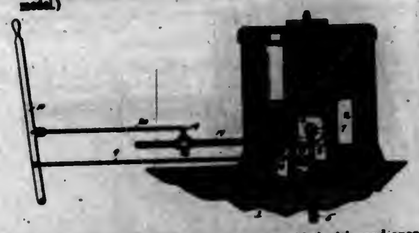
605,801. BRAKE. JOHN SANDFORD, Sr., Wyndmoor, Pa. Filed July 21, 1897. Serial No. 645,462. (No model.)

Claim.—1. In a vehicle-brake, a lever fulcrumed intermediate its ends and means for engaging and holding said lever, in combination with a brake-shoe for engagement with one of the vehicle-wheels, flexible connections between the ends of said shoe and the brake-lever, one of which is connected to the fulcrum of the lever, and the other to the shorter arm of said lever, and a stay-rod or brace connected at its forward end to the running-gear, and at its opposite end to said brake-shoe, substantially as described.



2. In a vehicle-brake, the combination with a lever fulcrumed intermediate its ends, of a brake-shoe, a strap secured to the outer surface of said shoe and projecting at its ends beyond the ends of said shoe, a flexible connection between one end of said strap and the fulcrum of the lever, a second flexible connection between the opposite end of said strap and the short arm of the lever, and a stay-rod or brace in front of said shoe, connected at one end thereto and at its opposite end to the running-gear, all arranged for joint operation, substantially as described.

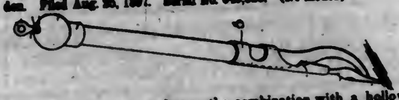
605,802. FURNACE FOR WORKING ZINC AND LEAD. REINHARD SCHNEIDER, Dresden, Germany. Filed Mar. 15, 1897. Serial No. 628,213. (No model.)



Claim.—1. The combination in a furnace for working zinc, of the retorts for containing the ore to be treated, each provided with an upper receiver *e* for the zinc-vapors to be condensed therein arranged on one end of the retort and a lower receiver *f* on the opposite end for the lead which emolts from the ore, and with means for collecting the zinc and the lead separated from one another; substantially as described.

2. In a furnace for working zinc; the combination with the retorts *c* of an upper receiver *e* for the zinc-vapors and a lower receiver *f* for the liquid lead, and of troughs *e'*, *f'* on the soles of said receivers for simultaneously collecting one the metallic zinc and the other the metallic lead; substantially as and for the purpose set forth.

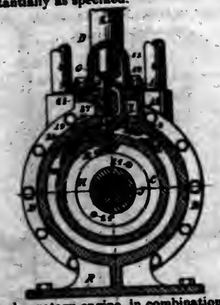
605,802.



605,808. SAND-BOX FOR LOCOMOTIVES. CHARLES P. WEBB, Hornellsville, N. Y. Filed Jan. 24, 1898. Serial No. 668,053. (No model.)

Claim.—In a sand-box for locomotives provided with sand-openings and sand-pipes leading therefrom, of sand-valves controlling said openings, an operating-lever, connection between said valves and lever, an air-jet pipe located within the sand-box and having nozzles arranged in line with the sand-openings, an air-supply pipe communicating with the jet-pipe and provided with a valve, a rod connection between said valve and the operating-lever, whereby the air-pipe valve is adapted to be opened by said lever after the latter has opened the sand-valves.

605,804. FOUNTAIN-PEN. OLOF WIKLER, Helsingborg, Sweden. Filed Aug. 26, 1897. Serial No. 649,220. (No model.)



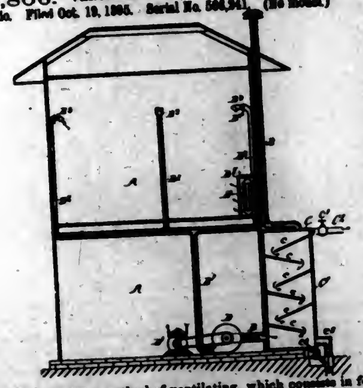
Claim.—1. In a reservoir-pen, the combination with a hollow body portion, of a flexible cap or bulb upon one end of said body portion, and an adjustable air-inlet valve projecting through an opening in said cap, the said valve provided with an inclined recess, substantially as and for the purpose set forth.

2. In a reservoir-pen, the combination with a hollow body portion, of a flexible closing-cap upon the upper end of said body portion provided with an opening, and a plug-valve adapted to fit within said opening provided with an inclined recess in one of its sides, whereby by a change of position of said plug-valve in said cap said opening may be completely closed or the size thereof regulated, as and for the purpose set forth.

605,805. ROTARY STEAM-ENGINE. ALFRED LEE, New Whatcom, Wash. Filed June 25, 1897. Serial No. 642,224. (No model.)

Claim.—1. In a duplex rotary engine, in combination, the sectional cylinder-casings A, B B and heads C C through which shaft J turns, the annular chambers 14 14 in which the piston-followers G G rotate, these piston-followers having packing-strips 15 15 and 16 16 held apart and against the exterior and interior circumference walls of the annular chambers 14 14, the flange I which is fixed stationary on the shaft J by being shrunken on the same and also by being keyed to the shaft-disks 26 by means of keys 24 24, this flange having a recess to receive the disk 26 and having bolted to it one of the piston-followers G at 23, the flange H having a recess to receive the shaft-disk 25, and having bolted to it one of the piston-followers G at 21, being keyed to the shaft-disk 25 by means of keys 24 24 so that the shaft shall rotate with it, but keyed loosely enough as to be longitudinally adjustable. this flange H also having a sleeve 31 which fits on shaft J so as to be movable longitudinally, this sleeve 31 having an adjusting-nut 32 threaded into its outer end with a left thread and onto the end of shaft J with a right thread, the shaft J having the fixed disks 25 and 26 onto which the flanges H and I are keyed, having one part 34 reduced to receive the sleeve 31, and having its extremity still further reduced and threaded to receive the adjusting-nut 32, substantially as specified.

2. In a duplex rotary engine, in combination, the sectional cylinder-casings, the annular chambers 14 14, the piston-followers G G, the rotating flanges H and I, the key-pins marked 24, the shaft J, the cam K of the shaft J located between the two shaft-disks 25 and 26, having the projections 27 and 28, the yoke F, having an irregularly-curved opening in which the cam K rotates, having a projection 30 against which the two projections 27 and 28 of the cam in its rotation impinge for the purpose of lifting the yoke and the valve and giving the valve its two unequal movements in each revolution of the piston, substantially as specified.



3. In a duplex rotary engine, in combination, the shaft J, the cam K of the shaft J located between the shaft-disks 25 and 26, having the projections 27 and 28, the yoke F having an irregularly-curved opening in which the cam K rotates, having a projection 30 against which the two projections 27 and 28 of the cam in its rotation thrust for the purpose of lifting the yoke F and the valve, this yoke consisting of two pieces securely bolted together so as to act as one, the lower portion having a bore 57 which fits about and reciprocates upon a stationary piston L, this bore having openings marked 56 about its circumference to admit steam within the bore above the piston L for the purpose of cushioning the stroke of valve, the stationary piston L, having packing-rings of the usual character, having the screw-adjustment extension 59 with jam-nut 60, for the purpose of adjusting the piston vertically and regulating the amount of steam compression in the bore of yoke, the cylinder-casing A to which this stationary piston is attached, substantially as specified.

4. In a duplex rotary engine, in combination, the shaft, the cam K of shaft, the yoke F having projections 30, in which yoke the cam K having projections 27 and 28 rotates to lift the same, having a bore in its lower portion to receive the piston L, the piston L having screw-adjustment extension 59 and jam-nut 60, the cylinder-casing A supporting the piston L, the slide-valve E securely bolted to yoke F so as to reciprocate with it, this valve having a top rib 52, a spring-lug 51, a coil-spring 44, and having ports 9 9 connecting with steam-space O and the ports 11 11 in the casing, having ports 10 10, connecting with ports 12 12 and 13 13 in the casing, having slots in its lower edge to receive the flanges H and I, having beveled edges 39 39, the packing-pieces 37 37 of valve, each having a projection 38 on one side at an angle of forty-five degrees, to which fit the beveled edges of valve at 39 39, each having also an L-shaped extension 40, which extend downward and are covered by the edges of flanges H and I, having also the springs 41 41 which hold the two pieces 37 37 against the valve, substantially as specified.

5. In a duplex rotary engine, in combination, the cylinder A, having an inlet steam-chamber N, the steam-chamber O in the cap-casing D, the channel in which the valve E reciprocates connecting the chambers N and O, the slide-valve E securely bolted to the yoke F so as to reciprocate with it, this valve having the top rib 52, the spring-lug 51 for receiving the spring 44, and the coil-spring 44 for the purpose of securing the positive movement of the valve, having slots in its lower edge for the purpose of receiving the flanges H and I, having beveled edges 39 39, the packing-pieces 37 37 of valve fitting against the beveled edges, this valve having also ports 9 9 communicating with the steam-chamber O and the ports 11 11 in the casing, having the ports 10 10 communicating with the ports 12 12 and 13 13 in the casing, the ports 11 11 and 13 12 in the casing and the channel connecting the same, the ports 15 13 between the valve and the casing

leading into the annular chambers 14 14, the sectional cylinder-casing and the rotating flanges H and I forming the annular chambers 14 14, the annular chambers 14 14, having the exhaust-ports 8 8, the piston-followers G G bolted to the rotating flanges H and I and rotating within the annular chambers 14 14 for the purpose of rotating the shaft, substantially as specified.

605,806. VENTILATING SYSTEM. JOSEPH MCCREERY, Toledo, Ohio. Filed Oct. 19, 1895. Serial No. 566,241. (No model.)

Claim.—1. The method of ventilating, which consists in forcing into an apartment streams of air at varying angles to one another whereby air-pressure from several streams in the same direction is avoided, as set forth.

2. A system of ventilation, which consists in an induct-pipe; a blower; an educt-pipe from such blower; and branch pipes leading from the educt, each branch pipe provided with an outlet, the several outlets being adjustable at varying angles to one another whereby the streams of air may be forced out at varying angles to one another and draft avoided, as set forth.

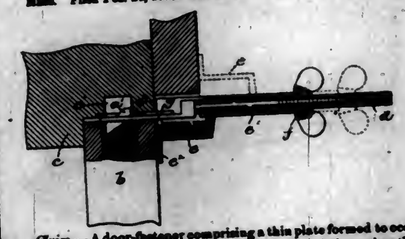
3. The combination of an air-induct and an air-educt, and a blower between them, of an air-supply pipe leading from the educt-pipe and having branch pipes, the latter being provided with nozzles or outlets which are adjustable on the branch pipes, whereby air may enter an apartment in streams of varying or different directions, as set forth.

4. In a ventilating system, the combination with an air-supply pipe, of an adjustable nozzle located at the end of the supply-pipe, said nozzle constructed of a plurality of sections articulated together, a guideway, an air gate or slide, and means to prevent the removal of the slide from the guideway, substantially as set forth.

605,807. SUPPORT FOR CURLING OR CRIMPING IRONS. JAMES H. PAIGE, Manchester, N. H., assignor to Lorin Edson Charles, Bedford, N. H. Filed Oct. 11, 1897. Serial No. 654,867. (No model.)

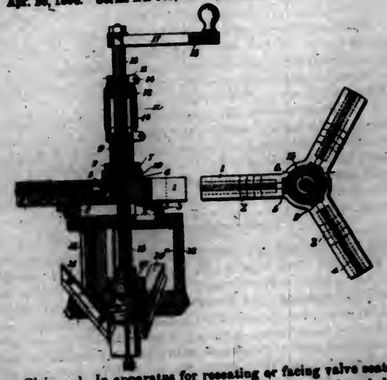
Claim.—1. A holder for curling or crimping irons during the operation of heating, comprising an enlarged non-elastic base, a smaller substantially tubular body portion formed as a continuation thereof, and an arm or support at the top for receiving and supporting the iron, substantially as described.

2. A holder for curling or crimping irons during the operation of heating, composed of a continuous piece of wire, having an enlarged base of a single coil, a series of smaller coils above the base, and a lateral loop or support extending on each side of the body portion, substantially as and for the purposes described.



605,808. BROOM-SUPPORT. JAMES H. PAIGE, Manchester, N. H., assignor to Lorin Edson Charles, Bedford, N. H. Filed Oct. 11, 1897. Serial No. 654,868. (No model.)

Claim.—1. As a new article of manufacture, a broom-support having a base-block provided with a diagonal kerf or groove, holes or apertures through the base intersecting the groove, and a clasp, substantially as shown and described, provided with a loop which rests in said groove and passes through said apertures, said loop bent to lock the clasp on the base.



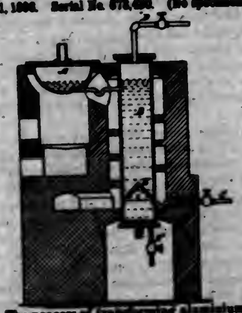
2. As a new article of manufacture, a broom-support having a base-block provided with a diagonal kerf or groove at the rear or back thereof, holes or apertures through the base and intersecting said groove, and a clasp, of one piece, inserted in the diagonal groove, the protruding ends or spring-arms of which are bent on a parallel plane to cross each other upon the base-block forming the head or loop, said spring-arms thence bent outward, thence inward and again outward to form the holding-arms and guide-fingers, substantially as shown and described.

605,809. DOOR-FASTENER. WALTER H. PLIMPTON, Boston, Mass. Filed Feb. 21, 1898. Serial No. 671,025. (No model.)

Claim.—A door-fastener comprising a thin plate formed to occupy the crevice between the swinging edge of a door and the casing thereof, and having at one side a spur formed to enter a recess in the casing, a screw-threaded shank affixed to said plate and offset therefrom, the shank being at the same side of the plate as the spur and the plate being substantially in line with one side of the shank, a recessed head movable on said shank, the recess of the head having a diameter exceeding the width of the plate, and a head-adjusting nut engaged with the shank, the said head having at its outer end a segmental flange which partially surrounds the plate and is formed to bear simultaneously on the door and on the casing, and said head being rotatable about the said plate in a plane at a right angle to the axis of the shank.

605,810. APPARATUS FOR RESEATING VALVES, BORING CYLINDERS, &c. PERCIVAL J. PURDY, Manchester, England. Filed Apr. 20, 1896. Serial No. 679,234. (No model.)

Claim.—1. In apparatus for reseating or facing valve seats and disks, the combination of stepped gripping-jaws, screw-threaded arms provided with bevel gear-wheels carrying said jaws, a hollow stem, a spindle in said stem, means for rotating and feeding said spindle, a nut provided with a bevel-gear mounted on said stem and means for holding the nut in position against the thrust of the bevel-gears, substantially as described.



2. In an apparatus for reseating or facing valve-seats, the combination of a casing provided with adjustable cutting-tools, stepped gripping-jaws, means for moving said jaws inwardly or outwardly in unison, a screw-threaded hollow stem, a spindle passing through said stem, means for feeding said spindle in said stem, consisting of an open-sided nut mounted on said stem, a collar mounted on said spindle and means for securing said collar to said spindle and an adjustable crank-handle for rotating said spindle, substantially as described.

605,811. NUT-LOCK. GEORGE B. BURTON, Brooklyn, N. Y., assignor of one-half to George S. Elliott, New York, N. Y. Filed Jan. 26, 1897. Serial No. 621,038. (No model.)

Claim.—In a nut-lock, the combination of a bolt having a screw-threaded longitudinally-grooved end, a nut with a groove registering with said bolt-groove, and a key having a body portion adapted to enter said registering grooves, and provided with a spring portion having a downwardly-extending fork adapted to simultaneously engage the threads on said bolt on opposite sides of said grooves, substantially as described.

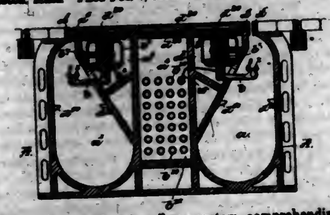
605,812. PROCESS OF MAKING ALUMINIUM SULFID. HENRY S. BLACKMORE, Mount Vernon, N. Y., assignor to the Pure Aluminium and Chemical Company, of West Virginia. Filed Dec. 31, 1895. Renewed Apr. 21, 1896. Serial No. 587,620. (No specimens.)

Claim.—1. The process of transforming aluminium oxid into aluminium sulfid which consists in exposing a fused bath containing dissolved aluminium oxid to the action of carbon-bisulfid vapor or gas substantially as described.

2. The process of transforming aluminium oxid into aluminium sulfid which consists in liquefying aluminium oxid by the action of heat and fused solvent fluxes, thus exposing the liquefied aluminium oxid to the action of carbon-bisulfid vapor or gas substantially as described.

3. The process for transforming aluminium oxid into aluminium sulfid which consists in fusing a mixture of cryolite (aluminium sodium fluorid) and potassium fluorid dissolving therein aluminium oxid and exposing the liquefied aluminium oxid to the action of carbon-bisulfid vapor or gas substantially as described.

4. The process for transforming aluminium oxid into aluminium sulfid which consists in passing carbon-bisulfid vapor or gas through a molten bath capable of liquefying aluminium oxid and introducing aluminium oxid into the same substantially as described.



605,813. BASIN-PLUG THIMBLE. FREDERICK S. CHASE, Waterbury, Conn. Filed Nov. 22, 1897. Serial No. 659,494. (No model.)

Claim.—1. A basin-plug thimble formed with two openings located opposite each other, and containing a sheet-metal strainer provided with flanges adapted to enter the said openings with which they are permanently engaged by flattening the strainer, which is concaved to permit its initial assemblance with the thimble.

2. A basin-plug thimble formed from sheet metal, having its upper end flanged and its lower end externally threaded, and formed at opposite points with two horizontally-arranged openings, and containing a sheet-metal strainer formed with two oppositely-projecting flanges adapted to enter the said openings with which they are engaged by flattening the strainer, which is concaved for its initial introduction into the thimble.

605,814. ELECTRIC-RAILWAY SYSTEM. HENRY A. CHASE, Boston, Mass. Filed Feb. 7, 1891. Serial No. 380,581. (No model.)

Claim.—1. An electric-railway system, comprehending the following instrumentalities, viz: a conduit having a slot-chamber; a conductor and guide having conducting and guiding surfaces located in said slot-chamber and in line vertically with the slot of the slot-chamber, independent tie-bars to connect the said surfaces at intervals, and a trolley-frame and trolley, the trolley and frame being adapted to be withdrawn or be inserted into the slot of the slot-chamber and to drop directly against and ride upon the said conductor, substantially as described.

2. An electric-railway system, comprehending the following instrumentalities, viz: a conduit having a slot-chamber; a conductor and guide having conducting and guiding surfaces located in said slot-chamber and in line vertically with the slot of the slot-chamber, independent tie-bars to connect the said surfaces at intervals, and insulated arms to support the said tie-bars, and a trolley-frame, and a trolley made as a wheel, free to roll on the conductor, substantially as described.

3. An electric-railway system, comprehending the following instrumentalities, viz: a conduit having a slot-chamber; a conductor located in said slot-chamber and in line vertically with the slot of said slot-chamber, and a guide substantially equidistant therefrom, a trolley arm or frame of a width less than the width of the opening between the slot-rails, an insulated conductor carried by said arm, a trolley adapted to enter wholly within said slot-chamber and ride on both the said conductor and guide, the guide aiding in keeping the trolley seated on the conductor, substantially as described.

4. The combination in an electric-railway system, of the following instrumentalities, viz: a series of yokes forming parts of a slot-chamber and having openings at one side in communication with accessible chambers forming parts of said yokes; a conductor, and a guide having a surface substantially equidistant therefrom; arms sustained in said accessible chambers and extended through the openings in one of the walls of said yokes, said arms presenting separated portions for the connection thereto of the ends of the material forming said conductor, a trolley-frame and trolley-wheel both free to drop bodily into the slot of the slot-chamber with the trolley-wheel fully within said slot-chamber, and free to roll on the parallel surfaces of said conductor and guide, substantially as described.

5. In an underground-conduit system for electric railways, the combination with a series of yokes forming parts of a slot-chamber, and a series of braces located between the opposite walls of the said yokes, of substantially parallel conducting and guiding surfaces, tie-bars to support the same entirely independent of one of the side walls of the yokes, the said tie-bars being supported by arms extended into accessible chambers near one of the sides of the yokes, the said surfaces being separated at intervals for the passage of water and dirt between them, and a trolley-wheel and its carrying-arm, both free to drop bodily into and through the slot-chamber and fall directly upon the said parallel conducting-surfaces, the conducting-surfaces being located above the said braces or struts, to operate, substantially as described.

6. In a conduit system for electric railways, the combination with a trough-like conductor presenting surfaces 3 and 2, separated for the whole or a portion of their length to leave an opening for the passage of dirt, &c., of a trolley-frame provided with a trolley or current-collector to make contact with the said conductor, and a plow, carried by the said trolley-frame, to enter the space between the said surfaces, substantially as described.

7. In a conduit system for electric railways, the combination with a conductor, and an independent guide separated for the whole or a portion of its length from said conductor to leave an opening for the passage of dirt, &c., of a trolley-frame provided with a trolley to make contact with the said conductor and guide, a plow carried by said trolley-frame to enter the space between the said conductor and guide, and means to raise the said plow, substantially as described.

8. In a conduit system for electric railways, the combination with a conduit having a slot-chamber, and a conductor presenting surfaces 3 and 2, one surface serving as a guide for the other, of a frame extended through the said slot and a brush carried by the said frame and engaging the said surfaces, substantially as described.

9. In a conduit system of electric railways, the combination with a slot-chamber, a conductor located therein and in line vertically with the slot in the slot-chamber, of a trolley-frame provided with a rolling-contact surface and adapted to descend freely through said slot and make a rolling contact with the said conductor, a trolley-arm adapted to be fastened to the car and to which the said trolley-frame is pivoted, an insulated conductor connected to said car extended through said trolley-frame and in communication with the said trolley-wheel, the said trolley-wheel and its frame being free to drop bodily through the slot-chamber and upon the said conductor, substantially as described.

10. In a conduit system of electric railways, the combination with a slot-chamber, a conductor located therein and in line vertically with the slot in the slot-chamber, of a trolley-frame provided with a rolling-contact surface and adapted to descend freely through said slot and make a rolling contact with the said conductor, and a trolley-arm adapted to be fastened to the car and to which the said trolley-frame is pivoted, and springs to act on opposite sides of the trolley-frame, substantially as described.

11. In a conduit system of electric railways, the combination with a main conductor located in the slot-chamber of the conduit, of a trolley-frame provided with a rolling-contact surface to make a rolling contact with the said conductor, a trolley-arm adapted to be fastened to the car and to which the said trolley-frame is pivoted, springs connected to the trolley frame and arm, and means to regulate or adjust the tension of said springs, substantially as described.

12. In a conduit system of electric railways, a trolley-frame consisting of metallic plates or pieces c^3, c^3; trolley-wheels c having bearings in antifriction-bushings carried by said plates; means to electrically connect the trolley-wheels to the plates c^3, c^3, insulating material to which said plates are secured, a conducting strip or piece extended through said insulating material, and metallic wear-plates c^5, c^5 secured to the insulating material, substantially as described.

13. In a conduit system of electric railways, a trolley-frame consisting of metallic plates or pieces c^3, c^3; trolley-wheels c having antifriction-bushings, means to electrically connect the trolley-wheels to the said plates or pieces, insulating material to which said plates are secured; a conducting strip or piece extended through said insulating material, plates c^5 c^5 secured to the insulating material, and a reinforcing or guard bar c, substantially as described.

14. The herein-described trolley-frame, it consisting of the plates c^3 c^3, an insulating piece or bar c^4 to which said plates are secured, contact-wheels c carried by the said plates, plates c^5 c^5, secured to the insulating plate or bar c^4, and a conducting strip or bar c^{10} extended through the insulating piece or bar and electrically connected to one or both of the plates c^3 c^3, substantially as described.

15. In a conduit system for electric railways, the combination with a conduit having a slot-chamber and an accessible chamber; of a conductor composed of surfaces 2, 3, having an opening between them, tie-bars to unite and strengthen the said members, and an insulator in the accessible chamber provided with an arm, to which said members are secured, substantially as described.

16. In a conduit system for electric railways, the combination with a series of yoke-shaped supporting-frames each provided with a slot-chamber and an accessible chamber, of strengthening-bars located in the slot-chamber to prevent inward buckling of the walls of the slot-chamber, substantially as described.

17. In a conduit system for electric railways, the combination with a conductor and guide 2, 3 made in sections, of insulators having split or bifurcated arms to form spring portions and to which the adjacent ends of adjoining sections may be rigidly secured, substantially as described.

18. The combination with a pipe and a conducting-wire therein, of a series of independent insulators mounted upon the said wire substantially in contact with each other, and having communicating external grooves to form passages for the circulation of air through the tubes from end to end, substantially as described.

19. In a conduit system for electric railways, a conduit and parallel guide having branches connected by a bridge, substantially as described, whereby a trolley may run from a main conductor upon a branch conductor, substantially as described.

20. In an electric street-railway system, a conductor presenting a series of yokes provided each with a slot-chamber, slot-rails connecting said yokes to thus provide a continuous slot-chamber from one to the next yoke, said slot-rails communicating with a chamber in the roadway between said yokes to form a continuous slot-chamber for the reception of the arm of a current-collector connecting with and depending from the car, a conductor and a guideway located in said slot-chamber each at opposite sides of a vertical plane intersecting the exposed slot at the surface of the slot chamber, the current-collector working between said conductor and guideway, a series of accessible chambers having removable covers, a series of insulated arms supported in said accessible chambers, and extending therefrom laterally to support said conductor in said slot-chamber, insulated feed-wires extended through a series of separate wireways laid in the street between said slot-chambers and yokes, and an accessible wire-chamber at intervals in which the feed-wires are accessible and from which they may be led to the insulated arms sustaining said conductors, substantially as described.

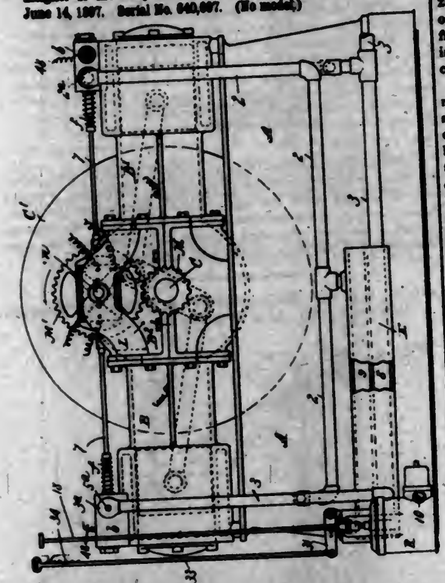
21. In a conduit for electric wires the following instrumentalities, viz: a yoke having a slot-chamber and an insulating-chamber communicating therewith through the side walls of the yoke, and below the slot-rails supported by said yoke, an insulated arm extended from said insulating-chamber through the wall of the yoke, a conductor mounted upon the end of said arm between it and the slot-rails, and shaped to permit a trolley-wheel to roll thereon, and a strut extended across the upper part of said slot-chamber from one to the other side of the yoke below and independent of said conductor-arm, substantially as described.

22. In a conduit system for electric railways, the combination with a conductor made in sections, of insulators having split or bifurcated arms to form spring portions and to which the adjacent ends of adjoining sections may be rigidly secured, substantially as described.

23. In a conduit system for electric railways, an underground conduit having a slot and slot-chamber, and a main conductor, and branches, to cooperate with a switch, said branches having an uninterrupted connection with said main conductor by means of a bridge, said conductor, bridge and branches affording an unbroken line of travel for a traveling contact carried by a car, substantially as described.

24. In a conduit system for electric railways, the combination with an underground conduit and a conductor therein adapted to receive a trolley, and branches, connected to said conductor by a bridge, of an inclined spur or arm, adjacent said conductor at the point of departure of said branch to receive said trolley and automatically raise it to enable it to run on said bridge, substantially as described.

25. In a conduit system for electric railways, an underground conduit having a slot and slot-chamber, and a main conductor, and branches, to cooperate with a switch, said branches having an uninterrupted connection with said main conductor by means of a bridge, said conductor, bridge and branches affording an unbroken line of travel for a traveling contact carried by a car and inclined spurs or arms adjacent said bridge to raise said contact thereon, substantially as described.



26. In an electric street-railway system, a conduit presenting a series of yokes presenting two slot-chambers, each chamber having as part of it two lines of slot-rails and sheet-metal plates shaped to conform to the outlines of the slot-chambers and connecting the yokes; a conductor and a guide occupying parallel positions in said slot-chambers and located each at opposite sides of a vertical plane intersecting the center of said slot-chamber at the street; a series of accessible chambers having removable covers; a series of insulated arms located in said accessible chambers and extended therefrom toward and to support the conductors of said slot-chambers; a series of insulated feed-wires extended through the street in wireways buried therein between said slot-chambers and said yokes; a series of accessible wire-chambers in which access may be had to said feed-wires and from which they may be led and connected to said insulated arms, and covers for said accessible wire-chambers, substantially as described.

27. In an electric street-railway system, a conduit presenting a series of yokes provided with slot-chambers, sheet-metal plates, and slot-rails connecting said yokes to thus provide a continuous slot-chamber for the reception of the arm of a current-collector connected with and depending from a car; a conductor and a guide located in said slot-chamber each at opposite sides of a vertical plane intersecting the exposed slot at the surface of the slot-chamber; a series of accessible chambers having removable covers; a series of insulated arms supported in said accessible chambers and extended therefrom laterally to sustain said conductor in said slot-chamber; insulated feed-wires extended through a series of separate wireways laid in the earth between said yokes, and accessible wire chambers at intervals in which the feed-wires are accessible and from which they may be led to the insulated arms sustaining said conductor, substantially as described.

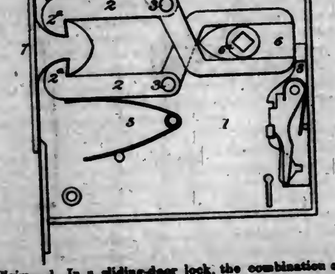
28. A frame or carrier composed of two metallic plates, a current-collector carried thereby, a conductor in communication with said current-collector and insulation covering said conductor and located between it and said plates, wear-plates applied to said insulation, outside of said conductor and out of contact with said metallic plates, and a coupling connected with the said insulated conductor by which to couple to said conductor or the wire leading to the motor of the car, said wear-plates obviating the easy destruction of the insulation of the conductor, substantially as described.

29. A frame or carrier composed of two metallic plates, a current-collector carried thereby, a conductor in communication with said current-collector and insulation covering said conductor and located between it and said plates, wear-plates applied to said insulation outside of said conductor and out of contact with said metallic plates, combined with a coupling to couple said conductor with the electric motor on the car, and a hood serving said coupling to exclude dirt, &c., substantially as described.

605,815. GAS-ENGINE. JAMES F. DURYEA, Springfield, Mass., assignor to the Duryea Motor Wagon Company, same place. Filed June 14, 1897. Serial No. 640,697. (No model.)

Claim.—1. In a hydrocarbon-engine, means for supplying volatilized hydrocarbon to said engine consisting of a supply-tank, a reservoir placed below the level of the bottom of said tank, a pipe connection from said tank to said reservoir, a float-actuated valve for automatically maintaining a quantity of liquid hydrocarbon in said reservoir, a pipe connection from said reservoir to the cylinders of said engine, an atomizer-tube in said pipe, communicating with the interior of said reservoir, an opening in said pipe for the admission of air, and means for regulating the quantity of air so admitted, a valve in said pipe for regulating the quantity of atomized hydrocarbon and air to be drawn into the said cylinders, and a heating-chamber in said pipe connection for heating said atomized hydrocarbon between said reservoir and said cylinders, substantially as described.

2. In a hydrocarbon-engine in combination, a supply-tank for liquid hydrocarbon, an intermediate reservoir between said tank and said engine, located on a lower level than said tank, suitable pipe connections between said engine, reservoir, and tank, means in said reservoir for regulating the quantity of hydrocarbon which can be drawn therefrom by one stroke of the piston of said engine, and means for automatically controlling the quantity of hydrocarbon in said reservoir, consisting of a float therein, an inlet-port communicating with said tank, a suitably-pivoted valve having a seat in said port, and a spring-arm attached thereto by one end and whose opposite end has a free engagement with said float, substantially as described.



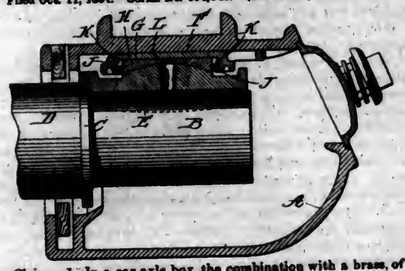
3. In a hydrocarbon-engine, means for operating the exhaust-valves consisting of the rod 7 having a suitable endwise movement, a valve 6 thereon, a beveled shoulder d', on said rod 7, the valve 5, closing the exhaust-port, the stem of which valve is engaged by said beveled shoulder for opening the valve, and a suitable spring 5^a on said valve-stem against which said opening movement takes place, combined with a suitable cam-operated rod 7, for opening said valve 6, and permitting said valve 5 to close before the closing of said first-named valve, substantially as described.

4. In a hydrocarbon-engine, means for atomizing liquid hydrocarbon and regulating the quantity of air to be mixed therewith, consisting of an atomizer-tube connected with a suitable reservoir containing a supply of hydrocarbon, a neck on said reservoir inclosing said tube, a plate 21 axially rotatable in said neck, a plate 24 fixed in said neck, and in contact with said plate 21, as shown, air-passages 25, in said plates, a central air-passage 22 through said plate 21, an opening R', through the side wall of said neck, and a pipe connection from said neck to the cylinder of said engine, substantially as described.

5. In a hydrocarbon-engine, means for atomizing liquid hydrocarbon and regulating the quantity of air to be mixed therewith, consisting of an atomizer-tube connected with a suitable reservoir containing a supply of hydrocarbon, a neck on said reservoir inclosing said tube, a plate 21 axially rotatable in said neck, a plate 24 fixed in said neck, and in contact with said plate 21, as shown, air-passages 25 in said plates, a central air-passage 22, through said plate 21, an opening R', through the side wall of said neck, and a pipe connection from said neck to the cylinder of said engine, a valve 29, and a heating-chamber in said pipe connection between said atomizer and the cylinder of said engine, substantially as described.

6. A gasolene or other hydrocarbon engine consisting of a plurality of cylinders connected to a common crank-shaft, a gasolene-supply tank, one exhaust-chamber common to said cylinders, pipe connections between the latter and said chamber, pipe connections between said supply-tank and said cylinders, a heating-chamber interposed in said last-named connection and adjoining said exhaust-chamber, an atomizer in said connections between said heating-chamber and said tank, means for regulating the supply and relative proportions of gasolene and air, a float-valve for automatically controlling the flow of gasolene from the supply-tank to said atomizer, and a closed-circuit electric igniting device in said cylinders, and means outside of the latter for automatically opening said circuit at a predetermined point in the stroke of the pistons of said engine, substantially as described.

605,816. SLIDING-DOOR LOCK. PLATO G. HENRY, Chicago, Ill. Filed Jan. 18, 1898. Serial No. 667,079. (No model.)

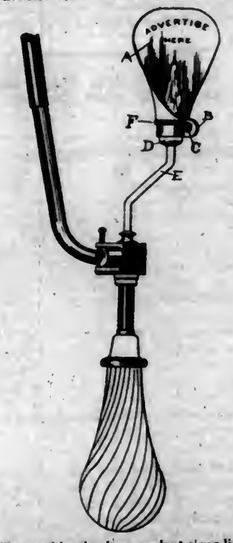


Claim.—1. In a sliding-door lock, the combination of pivoted catches one of which is capable at all times of pivotal movement, a rocking cam for opening the catches, and means adapted to engage the cam to hold the same against movement, substantially as set forth.

2. In a sliding-door lock, the combination of pivoted catches one of which is capable at all times of pivotal movement, a cam mounted on the knob-spindle hub and adapted to open the catches, and means for locking the cam against movement, substantially as set forth.

3. In a sliding-door lock, the combination of pivoted catches capable at all times of pivotal movement, a cam having a flat rear face and adapted to open the catches, springs to hold the catches normally closed, and a locking-bolt adapted when thrown to slide across the flat rear face of the cam and hold the cam against movement, substantially as set forth.

4. In a sliding-door lock, the combination of pivoted catches, a rocking cam operating to open the catches, and a key-bolt adapted, when thrown, to lock the cam, one of said catches being at all times free to have pivotal movement irrespective of the position of the cam or the key-bolt, substantially as set forth.

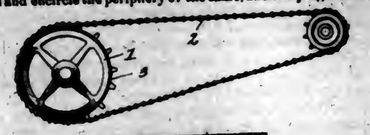


605,817. CAR-AXLE BEARING. HARRY A. FRITH, Chicago, Ill., assignor to the Universal Car Bearing Company, New York, N. Y. Filed Oct. 11, 1897. Serial No. 654,848. (No model.)

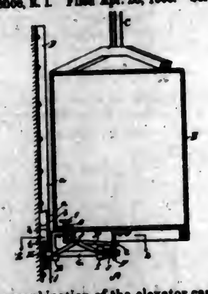
Claim.—1. In a car-axle box, the combination with a brass, of a key having a circular recess and an inwardly-extending flange, a bearing located between the brass and the key, lips on said bearing, and lugs turned down from the flange to permit the passage of the lips and adapted to be turned up to prevent the bearing from becoming disengaged from the key, substantially as described.

2. In a car-axle box, the combination with a brass, of a bearing provided with laterally-extending lips, a key having a circular recess on its under side to receive the bearing, an inwardly-extending annular flange around the lower edge of the circular recess in the key, said flange having one or more lugs turned down therefrom to permit the bearing to be inserted in the recess in the key, said lugs being kerfed and turned up after the bearing is arranged in place to prevent the bearing from becoming disengaged from the key, substantially as described.

605,818. PENDENT CIGAR-LIGHTER. HOWARD GIDDINGS, Chicago, Ill. Filed Nov. 3, 1897. Serial No. 657,207. (No model.)



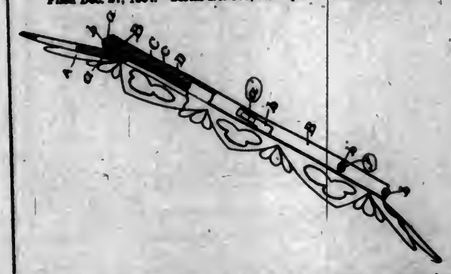
Claim.—The combination in a pendent cigar-lighter of the shield A, having a bead on the neck and lugs on the flaps, said lugs provided with a clamp-screw C, the bell-shaped cup having a screw-thread in the bottom part and a rim on the upper or top part, adapted to fit the said bead on the neck of said shield, the gas-tip E provided with a thread adapted to receive the said cup and shield, substantially as described.



605,819. SPROCKET-WHEEL FOR BICYCLES. WILLIAM GRADY, Cortland, N. Y., assignor of one-half to Irving B. Fairchild. Filed Oct. 16, 1897. Serial No. 655,395. (No model.)

Claim.—1. The combination with a sprocket-wheel and chain of a band of fibrous material encircling the periphery or pitch-line of said wheel and carrying a lubricant.

2. The combination, with a sprocket-wheel and driving-chain, of a band of felt, suitably apertured to fit over the teeth or cogs of the wheel and encircle the periphery of the same, and carrying a lubricant.

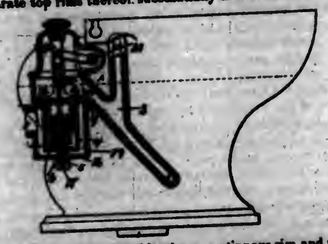


605,820. SAFETY-BRAKE FOR ELEVATORS. GEORGE HADCOCK, Providence, R. I. Filed Apr. 23, 1898. Serial No. 678,663. (No model.)

Claim.—The combination of the elevator car, the slotted clamping-track, arranged exteriorly of the car, the sliding bar provided with the clamping-head, the toggle-links for operating the sliding bar in one direction, means for operating the sliding bar in the opposite direction, the lever connected with the toggle-links, and the pedal connected with the lever, substantially as described.

605,821. PICTURE-FRAME. MAX HERSKOVITS, Chicago, Ill. Filed Dec. 27, 1897. Serial No. 663,736. (No model.)

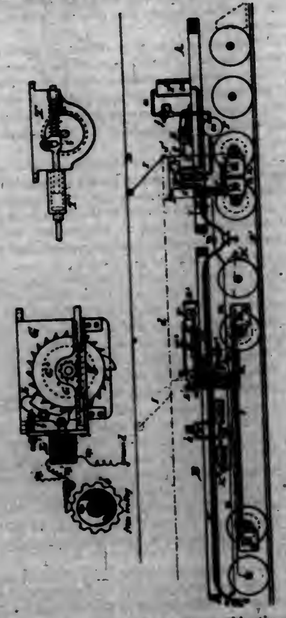
Claim.—As an article of manufacture, the combination in a glass frame of the rim *c*, having lugs on the outside and horizontal apertures; the binding-ring B provided with inclining grooves *b*, adapted to engage the said lugs; the perforations in said ring adapted to receive the pins; the pins *f* adapted to fix the ring to the frame; substantially as described.



605,822. REGISTERING-RING. WILLIAM G. HOMAN, Meriden, Conn. Filed Mar. 3, 1898. Serial No. 672,967. (No model.)

Claim.—In combination a transversely-slotted resilient ring, and a numeral-ring slightly less in its internal diameter when said parts are unassembled, than the external diameter of said first ring, slipped thereover.

605,823. WATER-CLOSET. JOSEPH W. SHARP, Jr., and JOHN W. GRAFFLAND, Philadelphia, Pa., assignors to the Haines, Jones & Cadbury, same place. Filed Nov. 2, 1897. Serial No. 657,159. (No model.)



Claim.—1. A water-closet fixture comprising a neck having its top part depressed, a bowl integral with the neck and having its top rim continuous and elevated above the neck, a water-chamber and valve-support integral with said neck and having a continuous top rim separate from the bowl-rim and elevated above the neck, and a water-inlet communicating with the bowl and chamber below the complete and separate top rims thereof, substantially as described.

2. In combination a bowl having a continuous rim and provided with an integral valve-support having a continuous top rim independent of and located below the bowl-rim and having a bottom rim, a two-part valve-casing whereof the parts are respectively seated all around the rims of the valve-support, and a screw connection for clamping the parts of the casing onto the last mentioned rims, whereby compressive stress is evenly distributed, substantially as described.

3. In combination a bowl, as earthenware, integrally provided with an open-ended valve-support, a two-part valve-casing whereof the respective parts are clamped together and onto opposite ends of the support, and an operating-handle wholly supported by and pivotally attached to one of said parts, substantially as described.

605,824. ELECTRIC RAILWAY. RUDOLPH M. HUNTER, Philadelphia, Pa. Filed Dec. 14, 1897. Serial No. 661,791. (No model.)

Claim.—1. In an electric railway, the combination of a pilot-car and a self-propelled railway-car adapted to be operated as a train, a controller on the self-propelled railway-car to govern the speed of the electric motors thereon, a fluid-pressure device for operating the controller, an electromagnetic device for governing the operation of the controller, and an electric circuit leading from the electromagnetic device to the pilot-car for governing the operation of said electromagnetic device from a distance.

2. In an electric railway, the combination of a pilot-car and a self-propelled railway-car adapted to be operated as a train, a controller on the self-propelled railway-car to govern the speed of its electric motors, a fluid-pressure device for operating the controller, an electromagnetic device for governing the operation of the controller, an electric circuit leading from the electromagnetic device to the pilot-car for governing the operation of said electromagnetic device from a distance, one or more electric motors to propel the pilot-car, a hand-regulator to regulate the speed of the motors of the pilot-car, and connecting devices between the hand-controller and the aforesaid electric circuit leading from the electromagnetic device whereby the distant controller is caused to move in accordance with the action of the hand-controller on the pilot-car.

3. In an electric railway, the combination of a pilot-car and a self-propelled railway-car adapted to be operated as a train, a controller on the self-propelled railway-car to govern the speed of its electric motors, a fluid-pressure device for operating the controller, an electromagnetic device for governing the operation of the controller, an electric circuit leading from the electromagnetic device to the pilot-car for governing the operation of said electromagnetic device from a distance, devices on the pilot-car for supplying the fluid under pressure, and connecting-pipes leading from the said devices to the fluid-pressure device for actuating the controller of the self-propelled car.

4. In an electric railway, the combination of a pilot-car and a self-propelled railway-car adapted to be operated as a train, a controller on the self-propelled railway-car to govern the speed of its electric motors, a fluid-pressure device for operating the controller, an electromagnetic device for governing the operation of the controller, an electric circuit leading from the electromagnetic device to the pilot-car for governing the operation of said electromagnetic device from a distance, devices on the pilot-car for supplying the fluid under pressure, connecting-pipes leading from the said devices to the fluid-pressure device for actuating the controller of the self-propelled car, and means also on the pilot-car for varying the fluid-pressure supplied to the said fluid-pressure devices on the self-propelled car.

5. The combination of two cars, one of which is provided with electric motors to propel it and an air-brake device to arrest its momentum and the other of which cars is provided with means to compress and store air under pressure, an electric controlling device to control the current supplied to the motors, a pneumatic device for operating said controller under a different pressure than that required to operate the brake, air-pipes leading from the compressing and storing devices on one car to the pneumatic devices and brake devices of the other car, and means for controlling the pressure of air in the pipe leading to the pneumatic devices for operating the controller and brake devices whereby either may be put into action at different times.

6. The combination of a main car provided with air-brake devices and electric motors to propel it, a braking-controller for converting the motors into braking-dynamos, pneumatic devices for operating the braking-controller, a pilot-car, devices for compressing and storing air under pressure on the pilot-car, air-pipes leading from the devices for storing the air on the pilot-car to the pneumatic devices of the electric-brake controller and the air-brake, and means on the pilot-car for governing the pressure of the air supplied to the main car whereby the electric brake and air-brake may be operated and controlled from the front of the train.

7. The combination of a main car provided with air-brake devices and electric motors to propel it, a braking-controller for converting the motors into braking-dynamos, pneumatic devices for operating the braking-controller adapted to operate when the pressure has been reduced below that necessary to apply the air-brake, a pilot-car, devices for compressing and storing air under pressure on the pilot-car, air-pipes leading from the devices for storing the air on the pilot-car to the pneumatic devices of the electric-brake controller and air-brake, and means on the pilot-car for governing the pressure of the air supplied to the main car whereby the electric brake and air-brake may be operated and controlled independently or simultaneously from the front of the train.

8. The combination of a car or vehicle, one or more electric motors to propel the car or vehicle, a speed-controller for varying the speed of the motors, an air-brake apparatus for arresting the momentum of the car or vehicle, a pneumatic device for operating the controller under a pressure in excess of that necessary for the air-brake, a common source of air-supply, and means to vary the pressure of the air-supply whereby the motors are cut out of operation as propelling-motors when the air-brake is applied.

9. The combination of a car or vehicle, one or more electric motors to propel it, a speed-controller for varying the speed of the motors, an air-brake apparatus for arresting the momentum of the car or vehicle, a pneumatic device for operating the controller under a pressure in excess of that necessary for the air-brake, a common source of air-supply whereby the motors are cut out of operation as propelling-motors when the air-brake is applied, and automatic valve de-

vices for limiting the maximum pressure of air capable of acting on the air-brake apparatus whereby all pressures in excess of that necessary for the air-brake alone are employed for operating the electric controller.

10. The combination of a car or vehicle, one or more electric motors to propel the car or vehicle, a speed-controller for varying the speed of the motors, an air-brake apparatus for arresting the momentum of the car or vehicle, a pneumatic device for operating the controller under a pressure in excess of that necessary for the air-brake, a common source of air-supply whereby the motors are cut out of operation as propelling-motors when the air-brake is applied, a braking electric controller for transforming the electric motors into braking-dynamos to retard or arrest the momentum of the car or vehicle, and pneumatic devices for governing the operation of the electric braking-controller under a pressure less than that necessary to apply the air-brake whereby the electric braking action may come into play after the car or vehicle has been partly slowed down.

11. In a car or vehicle, the combination of one or more electric motors to propel it, a speed-controller for governing the speed of the motors, a braking-controller for transforming the motors into braking-dynamos, independent fluid-pressure devices for governing the operation of the speed and braking controllers respectively under different pressures whereby the speed-controller may be cut out of action when the braking-controller is in action and vice versa, and means for varying the pressure of the fluid upon the independent fluid-pressure devices.

12. In a car or vehicle, the combination of one or more motors to propel the car or vehicle, an electric speed-controller governing the speed of the motors, a reversing-switch for reversing one of the elements of the motors to change the direction of travel of the car or vehicle, a pneumatic device for operating the speed-controller, an electromagnetic device for controlling the operation of the speed-controller, an electromagnetic device for operating the reversing-switch, and a pneumatic device for locking the reversing-switch in either of its positions.

13. In a car or vehicle, the combination of one or more motors to propel the car or vehicle, an electric speed-controller governing the speed of the motors, a reversing-switch for reversing one of the elements of the motors to change the direction of travel of the car or vehicle, a pneumatic device for operating the speed-controller, an electromagnetic device for controlling the operation of the speed-controller, an electromagnetic device for operating the reversing-switch, a pneumatic device for locking the reversing-switch in either of its positions, a source of pneumatic pressure common to both of the pneumatic devices, and means to vary the pressure of the fluid within the said devices whereby the reversing-switch is locked against movement excepting when the speed-controller is out of operation.

14. In a car or vehicle, the combination of one or more motors to propel the car or vehicle, an electric speed-controller governing the speed of the motors, a reversing-switch for reversing one of the elements of the motors to change the direction of travel of the car or vehicle, a pneumatic device for operating the speed-controller, an electromagnetic device for controlling the operation of the speed-controller, an electromagnetic device for operating the reversing-switch, a pneumatic device for locking the reversing-switch in either of its positions, a source of pneumatic pressure common to both of the pneumatic devices, means to vary the pressure of the fluid within the said devices whereby the reversing-switch is locked against movement excepting when the speed-controller is out of operation, and an electric circuit common to the electromagnetic device for controlling the operation of the speed-controller and for operating the reversing-switch.

15. In an electrically-propelled train, the combination of a pilot-car, two tanks adapted to contain a fluid under different pressures, a compressor to supply air to both tanks, pipes leading from both tanks to a pipe-coupling at the end of the pilot-car, valve devices to connect either one of the tanks or the atmosphere with the pipe terminating in said coupling whereby different pressures may be supplied to the train or the pressure in the pipes of the train may be relieved to any degree, electric motors to propel the train, and regulating devices for controlling the operation of the electric motors operated by the fluid-pressures controlled on the pilot-car.

16. In a pilot-car for trainwork, the combination of two tanks adapted to contain a fluid under different pressures, a compressor to supply air to both tanks, pipes leading from both tanks to a pipe-coupling at the end of the car, valve devices to connect either one of the tanks or the atmosphere with the pipe terminating in said coupling whereby different pressures may be supplied to the train or the pressure in the pipes of the train may be relieved to any degree, an electric circuit carried on the pilot-car and terminating at the rear in an electric coupling whereby electric connection may be made with circuits on the cars of the train, and a hand-controlled switch for governing the current supplied to said circuit.

17. In a pilot-car for trainwork, the combination of two tanks adapted to contain a fluid under different pressures, a compressor to supply air to both tanks, pipes leading from both tanks to a pipe-coupling at the end of the car, and valve devices to connect either one of the tanks or the atmosphere with the pipe terminating in said coupling whereby different pressures may be supplied to the train or the pressure in the pipes of the train may be relieved to any degree, an electric circuit carried on the pilot-car and terminating at the rear in an electric coupling whereby electric connection may be made with circuits on the cars of the train, a hand-controlled switch for governing the current supplied to said circuit, one or more cars supplied with electric motors, pneumatically-actuated controlling and air-brake devices, and means on said cars receiving supply of air and electric current from the pipes and circuits on the pilot-car for governing the operation of the motors and air-brakes on the cars.

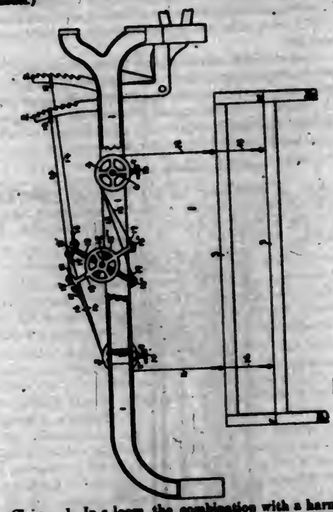
18. In a pilot-car for trainwork, the combination of two tanks adapted to contain a fluid under different pressures, a compressor to supply air to both tanks, pipes leading from both tanks to a pipe-coupling at the end of the car, and valve devices to connect either one of the tanks or the atmosphere with the pipe terminating in said coupling whereby different pressures may be supplied to the train or the pressure in the pipes of the train may be relieved to any degree, and an automatic pressure-valve interposed between the compressor and the tank to contain the lower pressure whereby communication with the reservoir is automatically shut off when its pressure reaches a maximum.

19. In a car or vehicle, the combination of one or more electric motors to propel the car or vehicle, a speed-controller to govern the speed of the motors, an independent braking-controller for transforming the motors into braking-dynamos by changing their electrical connection, and connecting means common to both controllers adapted to operate the said controllers alternately to put either into action but only at different times.

20. In a car or vehicle, the combination of one or more electric motors to propel the car, a speed-controller to govern the speed of the motors, an independent braking-controller for transforming the motors into braking-dynamos by changing their electrical connections, and connecting means common to both controllers adapted to operate the said controllers alternately to put either into action but not both into action at the same time and also to permit both to be out of action at one time.

21. The combination in a car or vehicle, of one or more electric motors to propel the car or vehicle, a controller to govern the speed of the motors, an automatic reversing-switch to reverse one of the elements of the motors, and an independent hand reversing-switch to modify the action of the automatic reversing-switch to compensate for cases where the car or vehicle has been turned end for end in making up the train.

22. In a car or vehicle, the combination of one or more motors to propel the car or vehicle, means to govern the speed of the motors, a main reversing-switch for reversing one of the elements of each of the motors, means under the control of the operator at a distance to operate the reversing-switch, and an independent reversing-switch which may be set in either of its extreme positions and unacted upon by the main reversing-switch or its operating devices.



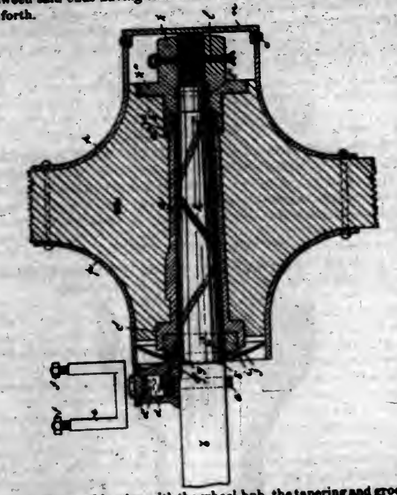
23. In an electrically-propelled train, the combination of two or more cars each provided with one or more motors, means to simultaneously reverse one of the elements of all of the motors on the train from the front of the train, and an independent current-reversing switch on each of the cars for reversing the polarity of one of the elements of the motors so that the polarity in the motors of any car may be changed or set upon making up the train to insure all of the motors propelling all of the cars in their proper direction under the control of the main reversing-switches.

24. In a car or vehicle, the combination of one or more motors to propel the car or vehicle, means to govern the speed of the motors, a reversing-switch for reversing one of the elements of each of the motors, a high-pressure pneumatic device for operating the means for governing the speed of the motors, a low-pressure pneumatic device for permitting the reversing-switch to be operated for reversing the motors, and means under the control of the operator for alternately operating the pneumatic devices for governing the speed of or reversing the motors.

25. In a car or vehicle, the combination of one or more motors to propel the car or vehicle, means to govern the speed of the motors, a reversing-switch for reversing one of the elements of each of the motors, a high-pressure pneumatic device for operating the means for governing the speed of the motors, a low-pressure pneumatic device for permitting the reversing-switch to be operated for reversing the motors, and means under the control of the operator for alternately operating the pneumatic devices for governing the speed of or reversing the motors consisting of an air-pipe, a source of compressed air of maximum pressure for operating the pneumatic device of means for governing the speed of the motors, and valve devices for supplying air at maximum pressure to the air-pipe or reducing the pressure in said air-pipe for the purpose of operating the pneumatic device of the reversing-switch.

26. The combination of a car or vehicle, one or more motors to propel the car or vehicle, a speed-controller for governing the speed of the motors, an air-brake device for arresting the momentum of the car or vehicle, a pneumatic device for operating the speed-controller of the motors when the pressure is greater than that necessary for the normal operation of the air-brake, a source of maximum air-pressure, an air-pipe leading from the source of maximum air-pressure to the pneumatic devices for the controller and also the air-brake devices, and means under the control of the operator for permitting air to flow to the air-pipe under a pressure greater than that necessary for the air-brake or to permit the air to escape from the air-pipe to relieve it from pressure to any point below a maximum pressure, and suitable means to limit the reduction of pressure to that which would throw the controller out of action but insufficient to put the brakes into action.

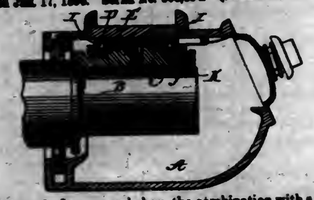
605,825. SHEDDING MECHANISM FOR LOOMS. GEORGE F. HOTCHKISS, Worcester, Mass., assignor to the Crompton & Knowles Loom Works, same place. Filed Feb. 10, 1897. Serial No. 622,812. (No model.)



Claim.—1. In a loom, the combination with a harness lever or jack, having its upright notched edge curved, two sheaves mounted on shafts in the loom-arches, and a harness-frame, of a two-armed lever centrally pivoted intermediate said sheaves, and a connection between the harness-lever and the upper end of the two-armed lever, a second connection from said upper end leading over a sheave to the harness-frame, and a third connection from the lower end of said two-armed lever leading over a sheave to the harness-frame, substantially as shown and described.

2. In a shedding mechanism for looms, the combination with the harness-frame, two sheaves supported between the arches, connections from said frame, leading over the outer edges of said sheaves to the lower and upper arm of a two-armed lever centrally pivoted between the loom-arches intermediate said sheaves, and having a circular portion intermediate its ends, and a connection from said lever to the harness lever or jack, of said harness lever or jack, having a curved notched edge, the curvature of which, at the central position of the harness lever or jack, corresponds to the arc of a circle, the center of which is at the point of connection, between the connection leading from the harness-lever and the two-armed lever, when said two-armed lever is in its central position, substantially as shown and described.

605,826. SELF-OILING AXLE. BENJ JAMIESON, Newark, N. J., assignor of two-fifths to Adolph Fuchs, same place. Filed Oct. 9, 1897. Serial No. 654,647. (No model.)



Claim.—1. The combination with the tapering axle having a spiral groove terminating at the smaller end of said axle at a chamber or recess *l'*, a wheel having a box *c*, a nut having its inner end fitted over said box, and its outer end secured to said axle and interiorly between said ends having said chamber or recess *l'*, substantially as set forth.

2. The combination with the wheel-hub, the tapering and grooved axle, the box *c*, having the cup-shaped inner end, the collar *j*, fitting said cup-shaped extremity and having the recess *j'*, and the guard *i*, concaved at the side toward said wheel-hub, of the lubricant-receptacle having the spout extending through said guard and into said collar and conducting the said lubricant into the groove of the axle, substantially as set forth.

3. The combination with the tapering axle having a reduced and threaded end and grooved periphery, of a hub having the box *c*, with a reduced outer end, a nut *k* adapted to be keyed to said axle and having a flange *k'*, and at its inner end forming a cylindrical socket receiving the reduced end of the box and interiorly having a recess or chamber *l'*, in connection with the groove of the axle, and means for supplying said groove with lubricant, substantially as set forth.

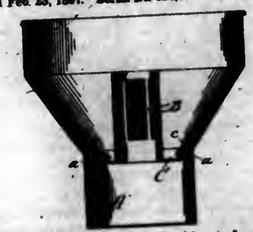
605,827. CAR-AXLE BEARING. FRANK B. HOLMES, St. Louis, Mo., assignor to the Universal Car Bearing Company, New York, N. Y. Filed Jan. 17, 1898. Serial No. 666,954. (No model.)

Claim.—1. In a car-axle box, the combination with a key having an inwardly-extending flange provided with an opening, of a bearing provided with lips and adapted to be held in the key by said flange, a plate for closing the opening in the flange, and means for securing said plate to the key, substantially as described.

2. In a car-axle box, the combination with a key having an inwardly-extending flange provided with an opening, of a bearing provided with lips and adapted to be held in the key by said flange, a plate for closing the opening in the flange and a pin adapted to secure the plate to the key to close the opening in the flange, substantially as described.

3. In a car-axle box, the combination with a key having an inwardly-extending flange provided with an opening, of a bearing provided with lips and adapted to be held in the key by said flange, a plate for closing the opening in the flange, a pin formed integral with the key and adapted to receive the plate and be riveted thereon to secure the plate to the key and close the opening in the flange, substantially as described.

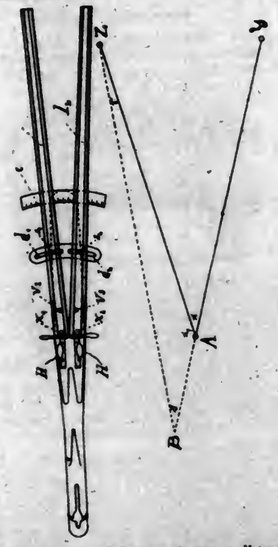
605,828. VESSEL-HANDLE. ALBERT R. PRITCHARD, Rochester, N. Y. Filed May 10, 1897. Serial No. 636,905. (No model.)



Claim.—1. The combination of a handle having a conical end

largest at the extremity and a longitudinal slot in the conical end; and a conical ferrule adapted for attachment to a vessel having its edges overlapping and fastened together and a portion of the ferrule forced into the slot, whereby the ferrule is contracted to fit tightly upon said conical end.

2. The combination of a handle having a conical and largest at the extremity and a longitudinal slot in said end; and a ferrule adapted for attachment to a vessel having its edges double-seamed together and the double-seamed edges of the ferrule forced into the slot, whereby the ferrule is contracted to fit tightly upon said end.

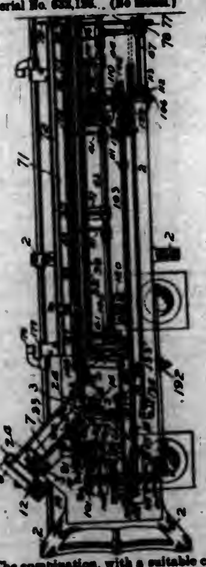


605,829. MILK-STRAINER. ARTHUR I. ROWLING, Waukegan, Ill. Filed Feb. 23, 1897. Serial No. 624,510. (No model.)

Claim.—1. The combination of a funnel and of a strainer provided with a cup arranged below the perforated portion of the strainer having an annular lip resting against the funnel when in use.

2. The combination of a funnel provided with an interior annular ledge and a strainer having a cup arranged below the perforated portion of the strainer and provided with an annular lip resting on the annular ledge when in use.

605,830. DISTANCE-MEASURING INSTRUMENT. ALESSANDRO GIOVANNI BATTISTA SOLDI, Gravedona, Italy. Filed Oct. 31, 1896. Serial No. 610,720. (No model.)



Claim.—1. As a new article of manufacture, a distance-measuring device having a stock, a chamber therein provided with a horizontally-extending slot, a shaft in said chamber, a drum having an angular slot therein mounted on said shaft, a lever adapted to rotate said drum, barrels pivotally secured to said stock, pins on the under side of said barrels entering said drum-slots, and means for determining the angular opening of said barrel; all of the said parts being combined substantially as and for the said purpose described.

2. A distance-measuring instrument having a stock provided near its forward end with a chamber having a horizontally-extending slot in the bottom part thereof, a shaft mounted in said chamber, a drum mounted on said shaft provided with an angular V-shaped slot, a lever rotatably actuating said shaft and drum and extending downwardly through said slot in the bottom of said chamber, a button on the end of said lever; pins on the under side of said barrels entering said angular slot, annularly-extending angular recesses in the upper surface of said stock near the central and forward end respectively thereof, a segmentally-curved slider in the centrally-located recess, said slider being provided with slots therein; other pins on the under surface of said barrels adapted to enter said slots, and a segmentally-formed scale in the remaining said angular recess, all of the said parts being combined as and for the purpose as described.

3. As a new article of manufacture a distance-measuring instrument having a stock pivotally secured thereto, barrels, pins on the under side of said barrels; said stock having a chamber therein under said pins, a shaft mounted in said chamber, a drum on said shaft having an angular V-shaped slot therein adapted to receive the aforesaid pins, means for rotatably actuating said drum, a lever on the under side of said stock near its forward end, annularly-extending recesses in the upper surface of said stock and a guide-arm and a scale respectively secured therein; all of the said parts being combined substantially as described.

4. As a new article of manufacture a distance-measuring instrument, barrels pivotally secured thereto, pins on the under surface of said barrels adapted to move in annular grooves in the upper surface of the stock, means for actuating said pins and a scale adapted to measure the angle included by said barrels, all of the said parts being combined substantially as and for the purpose described.

605,831. APPARATUS FOR WEAVING COILED-WIRE FABRIC. CLARENCE G. WHITE and MARSHALL B. LLOYD, Minneapolis, Minn., assignors to the Woven Wire Machinery Company, same place. Filed Apr. 14, 1897. Serial No. 632,198. (No model.)

Claim.—1. The combination, with a suitable coiler, of a receiver into which the coiled wire passes after it leaves the coiler, a series of pins or projections located in said receiver in the path of the advancing wire, and means for moving said receiver and said pins toward or from said coiler.

2. The combination, with a suitable coiler, of a receiver into which the coiled wire passes after it leaves said coiler, two series of transverse pins arranged to project into said receiver from the opposite sides thereof, means for moving said pins into and from said receiver, and means for giving said receiver a back-and-forth longitudinal movement and for moving said pins with said receiver.

3. The combination, with a coiler, of the longitudinally-movable guide or receiver 34, the vertical pins 35 arranged in said receiver, the oppositely-projecting transverse pins 55, and the plate 39 arranged to project over the opening of said receiver and provided with the beveled edge 40, and means for moving said receiver toward and from said coiler.

4. The combination, with the longitudinally-movable receiver 34 and the transverse pins 55, and means for alternately moving said pins, of means whereby either set of said pins may be moved independently of the other.

5. The combination, with the receiver, of the transverse pins, the rock-shafts for moving said pins, and means whereby either of said rock-shafts may be moved independently of the other.

6. The combination, with the receiver and the transverse pins 55, the rock-shafts 56 and 57 for moving said pins provided with the arms 59 and 60, and the link 61 connecting said arms and provided with the T-shaped slot 62, for the purpose set forth.

7. The combination, with the longitudinally-movable receiver, of the transverse pins 55, the bars 52 to which said pins are secured, and the rock-shafts provided with arms having forked ends engaging said bars 52, whereby said bars are permitted to move longitudinally with said receiver.

8. The combination, with a suitable coiler, of the receiver comprising the stationary section and the movable section arranged in line therewith.

9. The combination, with the coiler, of the stationary section 34', the movable section 34, and the roll 142 arranged in said stationary section.

10. The combination, with a suitable coiler, of the stationary section 34', the movable section 34 arranged in line therewith, the roll 142 arranged in said stationary section, and the projections 144 and 145 provided with the spiral passage 146'.

11. The combination, with the receiver, of the roll 142 arranged therein, the projections 144 and 145 provided with the spiral passage 146', and means for severing the wire after it passes through said spiral passage, for the purpose specified.

12. The combination, with the receiver having a spiral passage provided therein through which the wire must pass, of a knife arranged to move across the end of said passage for severing the wire, and means whereby said knife covers the end of said passage until just before the next wire moves through said spiral passage.

13. The combination, with the receiver, of the shaft 149, means for moving said shaft, the plate 155 arranged upon said shaft, the finger 156 pivotally supported upon said plate and provided with a weighted lower end, and the spring 158', for the purpose set forth.

14. The combination, with the coiler and the receiver, of the vertical plate 32 pivotally supported between said coiler and said receiver at one side of the path of the moving wire, and a stop mechanism arranged to be operated by the movement of said plate, for the purpose set forth.

15. The combination, with the coiler and receiver, of the vertical plate 32 pivotally supported upon the frame of the machine, the stop mechanism, the latch controlling said stop mechanism, the lever 31 connected to said latch and adapted to be operated by said plate 32, for the purpose set forth.

16. In a machine for weaving coiled-wire fabric, the combination, with the feed-rolls and means for driving said rolls, of means for cutting the wire, and means for imparting the necessary movement to the fabric, and mechanism for operating the wire-cutting and fabric-moving devices, and means for connecting or disconnecting said last-named mechanism with the means for driving the feed-rolls.

17. The combination, with the feed-rolls and coiler, and means for driving said feed-rolls, of the shaft 28 from which the wire-cutting and fabric-moving devices are operated, the shaft 92 arranged to be driven from the shaft of one of the feed-rolls and provided with the bevel-gear 91 and the pinion 93, said pinion and gear being loosely mounted on said shaft, the movable arm 96 carrying the pinion 94 arranged to engage said pinion 93 and to be thrown into or out of connection with the gear upon said shaft 28, whereby the wire-cutting and fabric-moving devices may be disconnected from or connected with the means for driving the feed-rolls.

18. The combination, with the feed-rolls and the shafts 7 upon which said rolls are mounted, one of said shafts being movable for the purpose of permitting said rolls to be separated, the short shaft 17 provided with a projection engaging the bearing of said movable shaft and provided with the arm 19 carrying the roll 20, and the reciprocating rod 22 provided with the projection 21 arranged thereon, for the purpose specified.

19. The combination, with the feed-rolls, of means for separating said rolls, said means comprising a suitable cam, an operating-rod controlled by said cam, and a belt or chain provided with projections arranged to engage and move said cam at suitable intervals.

20. The combination, with means for separating the feed-rolls, of operating means therefor comprising a suitable cam, an endless chain or belt provided with suitable projections arranged to engage and move said cam at suitable intervals, and means for supporting and moving said belt.

21. The combination, with the rotatable cam 27 provided with the plate 27', the chain or belt having projections arranged to engage said plate 27', means for supporting and moving said chain or belt, and means controlled by said cam for separating the feed-rolls, cutting the wire, and moving the last coil of wire in the receiver, for the purpose set forth.

22. The combination, with the coiler and receiver, of means for alternately moving said receiver to or from said coiler, and means operating at desired intervals for intermitting the movements of said receiver, for the purpose set forth.

23. The combination, with the coiler and receiver, provided with the oppositely-projecting transverse pins, of means for moving said receiver toward or from said coiler, means for moving said pins into or from said receiver, and means operating at desired intervals for intermitting the movements of said receiver and said pins.

24. The combination, with the coiler and the receiver, of the transverse pins adapted to project from opposite sides into said receiver, a plate arranged upon said receiver and adapted to partially cover the open top thereof, means for longitudinally moving said receiver, means for moving said pins into or from said receiver, means for moving said plate, and means operating at desired intervals for intermitting the movements of said receiver, said pins and said plate.

25. The combination, with the longitudinally-removable receiver, of means for moving said receiver, comprising the shaft 106, a connection between said shaft and said receiver, the plate 110 secured upon said shaft, the loosely mounted sprocket-wheel 105 arranged upon said shaft, and the chain or belt 103 provided with suitable projections 111 adapted to engage the plate 110 for the purpose of turning said shaft.

26. The combination, with the receiver, of means for moving said receiver, comprising a suitable shaft 106, the plate 110 secured upon said shaft, a sprocket-wheel mounted loosely upon said shaft, a chain or belt passing over said sprocket-wheel and provided with projections arranged to engage the ends of said plate, and means for moving said plate at suitable intervals out of the path of the projections upon said chain or belt.

27. The combination, in a machine for weaving coiled-wire fabric, with means for feeding and severing the wire, of a receiver into which said wire passes and in which it is interlocked with the coils of the preceding wire, of connected mechanism for operating the wire feeding and severing devices and for moving said receiver in the intervals between the feeding of the wire, for the purpose set forth.

28. In a machine for weaving coiled-wire fabric, the combination with means for feeding, coiling, and severing the wire, of a receiver into which said wire passes and in which it is interlocked with the preceding coils, means for moving said receiver toward and from said coiling means in the intervals between the operation of the feeding and coiling mechanism, and means for intermitting the movement of said receiver.

29. The combination, with the receiver and the pins arranged therein, of the wires connected to said pins.

30. The combination, with the receiver and the pins arranged in said receiver, of the wires connected to said pins, and the spring-loops connected to said wires, for the purpose set forth.

31. The combination, with means for forming the fabric, of means for longitudinally moving the wires after the fabric is formed for the purpose of evening the ends of the fabric.

32. The combination, with means for forming the fabric, of means operating upon the ends of the wires for evening up the fabric, for the purpose set forth.

33. The combination, with means for forming the fabric, of means for evening the ends of the fabric, and means for trimming one or both ends of the wire, for the purpose set forth.

34. The combination, with means for forming the fabric, of means for evening the fabric, means for trimming one or both ends of the wires, and means for crushing the ends of the coils, for the purpose set forth.

35. The combination, with means for forming the fabric, of means for forming a slack in one portion of the fabric, and means for moving the wires in such slack portion of the fabric, for the purpose of evening the fabric.

36. The combination, with means for forming the fabric, of the movable evening-plate, and means for operating said plate.

37. The combination, with the wires and the spring-loops over which the fabric passes, of the movable evening-plate, and means for operating said plate.

38. The combination, with means for forming a slack in the fabric, of the movable evening-plate arranged to engage the ends of the wires in the slack portion of the fabric, and means for moving said plate.

39. The combination, with the wires and the spring-loops over which the fabric passes, of means for moving the wires for evening

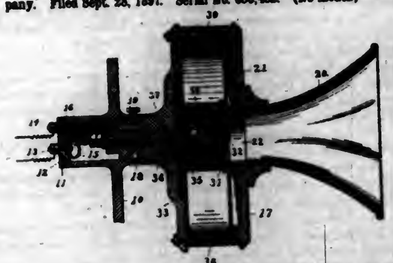
the fabric, and means for trimming the ends of the wires at one edge of the fabric.

40. The combination, with the movable evening-plate 162, of the rod 165 connected thereto, the spring 168, the projection 170 secured upon said rod, and the ratchet-wheel 175 engaging said projection, for the purpose set forth.

41. In a machine of the class described, the combination, with a reel and a wire-coiler, of a tripping mechanism arranged between said reel and said coiler, and over which the wire passes, said tripping mechanism being adapted to be moved and operated when the wire becomes caught or tangled or too great a tension is placed thereon, and a stop mechanism controlled by said tripping mechanism.

42. In a machine of the class described, the combination, with the coiler and the reel, of a tripping mechanism arranged between said coiler and reel and adapted to be operated by the wire when it does not feed freely from said reel.

43. In a machine of the class described, the combination, with a coiler, of independent reels, a tripping mechanism arranged between said reels and said coiler, and adapted to be engaged by the wires passing from both reels and to be operated when either wire does not feed freely from its reel, for the purpose set forth.



44. In a machine of the class described, the combination, with the coiler, of the rolls 199 over which the wires pass before reaching said coiler, the slides upon which said rolls are mounted, and the tripping mechanism controlled by said slides

45. In a machine for making coiled-wire fabric, the combination with parallel independent coiling-mandrels, of a rotatable section provided upon each mandrel, means upon said rotatable section for engaging the running wire, and independent means for adjusting said sections.

46. In a wire-coiler, the combination, with the parallel spirally-grooved mandrels, each provided at its forward end with a rotatable adjustable section, having a lug or shoulder thereon, of means for independently adjusting each of said sections, for the purpose set forth.

47. The combination, with the spirally-grooved mandrel 207 and means for feeding the wire thereto, of the adjustable pin 221 arranged over said groove and adapted to press upon the wire as it passes through said groove, for the purpose set forth.

605,882. TELEPHONE-TRANSMITTER. WILLIAM H. SUNDERS, Worcester, Mass., assignor to Lars M. Petterson and Carl J. Ekstedt, same place, as trustees for the Reliable Electric Manufacturing Company. Filed Sept. 28, 1897. Serial No. 653,402. (No model.)

Claim.—In a telephone-transmitter, the combination of a casing 17 having a mouthpiece 20, a metallic diaphragm 21, a plurality of screws having springs adjustably coiled thereon for holding the diaphragm in place, a contact-plate 31 carried by said diaphragm, a diaphragm 33, a contact-plate 35 secured thereon, a central adjusting-screw having nuts for regulating the distance between said contact-plates, a body of powdered carbon confined between the contact-plates, and a felt washer 34 secured on the contact-plate 35 in position to confine the body of powdered carbon, and to engage an inclined or chamfered edge on the contact-plate 31, substantially as described.

605,883. FASTENER FOR GLOVES, &c. WILLIAM S. RICHARDSON, Boston, Mass. Filed Mar. 13, 1897. Serial No. 627,295. (No model.)

Claim.—1. As an improved article of manufacture, a socket-piece from which a complete socket member of a ball-and-socket fastener is formed in the act of securing said piece to the glove or other article on or with which said member is used, having a preformed separable flange surrounding a yielding socket-entrance, a top section, separate, foldable, resilient sides substantially parallel with each other, integral with the top section and preformed flange, which sides are adapted in the act of setting the piece to be separated in relation to each other, folded outwardly to form a fastening-flange, provide a ball-holding cavity within the material between the flanges, complete the socket-entrance and impart resiliency thereto.

2. A socket-piece from which a complete socket member of a ball-and-socket fastener is formed in the act of securing said piece to the glove or other article on or with which said member is used, having a preformed separable flange surrounding a yielding socket-entrance, the side edges of which flange abut when in their normal relation to each other, a top section, separable, foldable, resilient sides substantially parallel with each other integral with the top section and preformed flange, as and for the purposes set forth.

3. A socket-piece from which a complete socket member of a ball-and-socket fastener is formed in the act of securing said socket-piece to the glove or other article on or with which the member is used, having a preformed separable flange surrounding a yielding socket entrance, a top section, separate, foldable, resilient sides integral with the top section and preformed flange, and shaped to slightly bulge outward, as and for the purposes set forth.

4. A socket-piece from which a complete socket member of a ball-and-socket fastener is formed in the act of setting said piece to the glove or other article on or with which the member is used, having a preformed separable flange surrounding a yielding socket-entrance, a top section, separate, foldable, resilient sides integral with the top section and preformed flange, and an outwardly-rounded bead or corrugation in the flange about the socket-entrance, all as and for the purposes set forth.

5. A socket member of a ball-and-socket fastener made from one piece of metal and having a top, separate arms or sections extending from said top outwardly and then back upon themselves, providing a sectional fastening-flange upon one surface of the glove or other article to which the member is secured, the said arms or sections extending through a hole in the said glove or other article at the lower edge of which hole they assemble and form a yielding socket-entrance, and from which socket-entrance they extend radially and make a fastening-flange upon the surface of the material opposite that upon which the said sectional fastening-flange bears, and which cooperates with the sectional folded flange in the fastening of the socket member.

6. The combination of a cap having an inwardly extending flange upon its under side forming a cavity, and a socket member having a top and resilient folded sides within said cavity, and which folded sides lap upon the inner surface of the flange and sections of which sides extend from said flange toward each other and provide a ball-receiving space or cavity.

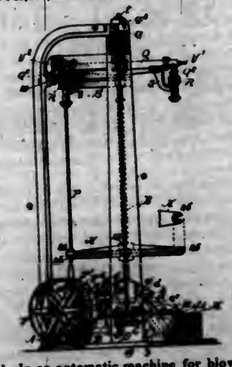
7. A socket member of a ball-and-socket fastener having a preformed separable flange surrounding a yielding socket-entrance upon one surface of the glove or other article to which the socket member is secured, a top section, and folded resilient arms extending from said top section outwardly and inwardly and through a hole in said glove, the said arms being integral with the top section and preformed flange and forming a fastening-flange upon the surface of said glove opposite that against which the preformed flange bears, yielding sides and a ball-holding cavity.

8. The combination, in a fastener, of a cap having a flange extending inwardly from its outer edge, with a socket member formed from a socket-piece having a preformed separable flange surrounding a yielding socket-entrance, a top section, separate, foldable, resilient sides integral with the top section and preformed flange, and which cap-section is combined with said socket-piece in the act of attaching it to a glove or other article by outwardly-extended folds of the said resilient sides within the cavity of the cap and upon the surface of the glove opposite that against which the preformed flange bears.

9. The combination of a socket member of a ball-and-socket fastener made from one piece of metal and having a top, separate arms or sections providing a sectional flange upon one surface of the glove and a yielding socket-entrance and a finishing-flange upon the other surface of the glove, and a support or backing upon which said first-named sectional fastening-flange bears, and having a hole through which the said arms extend, and which washer is of a size not to restrict or impede the yielding action of said arms.

10. The socket member above described, consisting of a socket-piece comprising the angular arms extending outwardly from a connecting portion and returning upon themselves to form an upper flange and a socket-entrance, each arm being farther extended outwardly at its extremity to form a finishing-flange, between which and said upper flange the material is to be held, with a part having yielding reinforcing-arms located immediately below said upper flange and held in contact with the yielding arms of the socket-piece and adapted to lie on the opposite side of said material from said finished flange, as and for the purposes set forth.

11. A socket member comprising a set socket-piece having when set yielding sides, an upper and a lower flange, said upper flange being formed by the upset sections of said yielding sides and said lower flange by extensions thereof, a cap adapted to inclose said upper flange, and yielding sections upon said cap which reinforce said yielding sides, as and for the purposes set forth.



12. In a socket member of a ball-and-socket fastener, a cap having a divergent flange, combined with a socket member having a top section and separate resilient sides folded down or extended laterally against said divergent flange within said cap, said folded sides when thus extended laterally within said cap serving to retain the latter in place, and said divergent flange when pressed against the material being flattened against the said folded sides and serving to form an extended fastening-flange upon the upper side of said material.

13. A socket-piece having sectional sides, a socket-entrance, a predetermined sectional flange surrounding the socket-entrance, and means such as a rib or bead in or upon said flange adapted to cooperate with a holding or setting die having an opposing rib or shoulder to maintain the predetermined shape of the flange and the bore of the socket during the setting of the socket-piece.

14. In a fastener, the combination of a cap having a cavity provided with a conical wall surrounding the entrance thereto and a closed top which is above said entrance, with a socket member in one piece comprising a closed end or top section which is inclosed within the cavity of the cap and bears against said top part of the cap, and separate arms which extend outwardly from the said top section to bear against the inner surface of said conical wall and then inward toward each other to form a conical cavity.

REISSUES.

11,668. MACHINE FOR BLOWING GLASS. MICHAEL J. OWENS, Toledo, Ohio, assignor, by direct and mesne assignments, to the Toledo Glass Company, same place. Filed May 5, 1896. Serial No. 679,572. Original No. 548,561, dated Oct. 22, 1895.

Claim.—1. In an automatic machine for blowing glass, an air-conduit, a sectional mold, a removable blowpipe, means for supporting the blowpipe in operative relation to the air-conduit and to the mold and means for automatically closing said mold after the introduction of the blowpipe in its support and for automatically opening the mold prior to the removal of said blowpipe.

2. In an automatic machine for blowing glass, an air-conduit, a sectional mold, a removable blowpipe, means for supporting the blowpipe in operative relation to the air-conduit and to the mold, means for automatically closing said mold after the introduction of the blowpipe in its support and for automatically opening the mold prior to the removal of said blowpipe, and means for cooling the mold while open.

3. In an automatic glass-blowing machine, a sectional mold, an air-conduit, a removable blowpipe, a support by which the removable pipe may be temporarily sustained in connection with the air-conduit and in operative relation to the mold, means for automatically opening and closing the mold, and means for imparting, with respect to the blowpipe and mold, a rotational movement of the one relative to the other.

4. In a glass-blowing machine, in combination, a mold and a mold-carrier, means for imparting movements to the carrier, an air-conduit that is movable in unison with the mold and a removable blowpipe which may be temporarily placed in connection with the air-conduit and in cooperative proximity to the mold, for the purpose substantially as set forth.

5. In a glass-blowing machine, a mold-carrier, with the mold thereon, and an air-supplying conduit, both movable, and having means for imparting traveling movements thereto in unison, a removable blowpipe, and means comprised in said machine for affording a support for the blowpipe whereby one end thereof may be in communication with the air-supplying conduit and the other in cooperative proximity to the mold, substantially as described.

6. In a glass-blowing machine, the combination with the vertical rotatable shaft having at its bottom a revoluble mold-carrier with the mold thereon, having at its top an air-conduit which is revoluble in conjunction with the mold-carrier, and having an intermediate part, supported by, and revoluble by reason of the rotation of the shaft, for affording a temporary support for the blowpipe whereby the top thereof may be in connection with said conduit, and the bottom in operative proximity to the mold, substantially as described.

7. In a glass-blowing machine, in combination, a mold-carrier, and a sectional opening and closing mold thereon, means for imparting movements to the carrier, an air-conduit that is movable in unison with the mold, a removable blowpipe which may be temporarily placed in connection with the air-conduit and in cooperative proximity to the mold, and mechanism for periodically and automatically opening and closing the mold-section, substantially as described.

8. In a glass blowing machine, in combination, a mold and a mold-carrier, means for imparting movements to the carrier, an air-conduit that is movable in unison with the mold, a removable blowpipe which may be temporarily placed in connection with the air-conduit and in cooperative proximity to the mold, a valve in said conduit and means for automatically and periodically operating the valve, substantially as described.

9. In a glass-blowing machine, in combination, a mold and a mold-carrier, means for imparting a traveling movement to the carrier, an air-conduit that is movable in unison with the mold, a blowpipe which may be placed in connection with the air-conduit and in cooperative proximity to the mold, and means for imparting a rotary movement to the blowpipe, substantially as and for the purposes set forth.

10. In a glass-blowing machine, in combination, a mold and mold-carrier, means for propelling the carrier to which the carrier is articulated whereby it may have a vertical swinging movement, a basin for a cooling liquid in the course of travel of the carrier, an air-conduit that is movable in unison with the mold, and a removable blowpipe which may be temporarily placed in connection with the air-conduit, and in cooperative proximity to the mold, for the purpose substantially as set forth.

11. In a glass-blowing machine, in combination, a sectional mold and a mold-carrier, means for propelling the carrier to which the carrier is articulated whereby it may have a vertical swinging movement, to descend into the basin, a basin for a cooling liquid in the course of travel of the carrier, an air-conduit that is movable in unison with the travel of the mold, a removable blowpipe which may be temporarily placed in connection with the air-conduit and in cooperative proximity to the mold and means for automatically opening the mold-sections as they approach the basin for the purposes substantially as set forth.

12. In a glass-blowing machine, in combination, the base A, the central vertical rotatable shaft having connected thereto near its bottom a revoluble mold-carrier with a mold thereon, having at its top an air-conduit which is revoluble in conjunction with the mold-carrier and having an intermediate horizontally-extended part for affording a temporary support for the blowpipe whereby the top thereof may be in connection with said air-conduit and the bottom in operative proximity to the mold, a gear, C, on said vertical shaft, the horizontal counter-shaft E, geared to the lower end of the vertical shaft, the driving-shaft, F, and gearing connecting it with the counter-shaft, substantially as described.

13. In a glass-blowing machine, the combination with the base having the track *m*, of the vertical shaft, B, connected to and radially extended from the shaft and having a friction-roll which runs on the track, the mold mounted on the carrier, a radial air-conduit carried by and extended from the upper part of the shaft and means for supporting, removably, a blowpipe in connection with the said conduit and in proximity to the mold, substantially as described.

14. In a glass-blowing machine, the combination with the base having the basin, M, therein and the track *m*, which runs around the top of the base and has its course contained in the basin of the vertical shaft, B, hinge-connected to, and radially extended from, the shaft and having a running bearing on said track, a mold mounted on the carrier and means for turning said shaft, substantially as described.

15. In a glass blowing machine, in combination, the rotary shaft, the carrier having a mold thereon, connected to and outwardly extended from a member of the shaft, and having a slide movably guided thereon which is provided with a projection or roller, a rib-like part along which the said projection runs for a portion of its course whereby the slide is outwardly maintained, and a cam in engagement with which the roller at another part of its course runs for forcing the slide inwardly and connections between the slide and

mold-sections whereby the outward and inward movements of the slide close and open the sectional mold, substantially as described.

16. In a glass-blowing machine, in combination, the base, A, the shaft, B, the collar, G, fixed on the shaft having the ear-lugs, *d*, the mold-carriers, H, H, with bifurcated inner ends, hinged to the ear-lugs, *d*, and having the slideways, *g*, the sliding block, L, on each of the carriers having combined therewith the stud, *h*, roller, *j*, and the annularly-arranged arms, *i i*, clamped on the upper end of the stud above the slide-block, by the nut, i^2, the mold-sections, *e e*, hinged on the mold-carriers, each having the outwardly-extending lug, e^2 and the connecting-rods, e^3, all substantially as described and shown.

17. In a glass-blowing machine, in combination, a mold and mold-carrier, means for imparting revoluble movements to the carrier, and an air-conduit that is movable in unison with the mold, a removable blowpipe which may be placed in connection with the air-conduit and in cooperative proximity to the mold, a depending tubular part, Q^2, rotatably mounted upon the revolubly-carried air-conduit, to form a continuation thereof and the part which receives the engagement therewith of the upper end of the blowpipe, a wheel or roller secured on said depending tubular rotatable part, and the arc-shaped fixture, S, on which the said wheel runs during a portion of the revoluble movement of the mold-carrier and air-conduit, substantially as described.

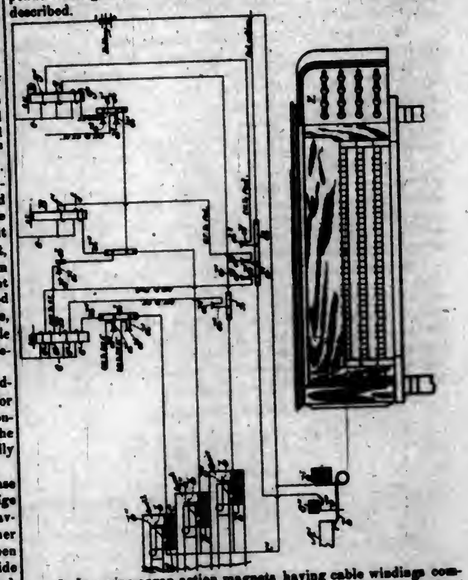
18. In a glass-blowing machine, the combination with the mold-carrier and the air-conduit Q, horizontally thereabove, and means for revolubly moving both in unison of the depending rotary tubular continuation of the conduit Q, having its lower end constructed for the engagement therewith of the upper end of a blowpipe, substantially as and for the purposes set forth.

19. In a glass-blowing machine, the combination with the base having the upstanding hub, *b*, with the outstanding arc-formed flange b^4, and the eccentrically-arranged cam-rib, *n*, of the mold carriers having the slide, L, with the rollers, *j* the sectional molds hinged together and mounted on the mold-carriers and means intervening between the slides and mold-sections actuated by the movements of the slide for opening and closing the mold-sections, substantially as described.

20. In a glass-blowing machine, the combination with the base, formed with the basin, of the revolubly-movable mold-carriers and hinged molds thereon, the mold-carriers being jointed to the support which revolubly propels it, whereby it may descend into the basin, means for opening the molds prior to such descent, springs for exerting a pressure to restrain the open molds from closing while in their lowered positions, and means for closing the molds after ascending from within the basin, substantially as described.

21. In a machine for blowing glass, one or more molds each consisting of hinged sections, a base on which said molds may move, having a depression in a portion of its surface in which said molds fall in succession when moved as aforesaid, means for moving said molds on said base and for causing the same, severally, to open and close automatically while descending into and rising out of said depression, combined and operating substantially as set forth.

22. In a machine for blowing glass, the combination of a sectional mold adapted to be opened and closed, a blowpipe, means for detachably supporting the blowpipe in operative relation to a source of air-supply and to the mold, the air-supply device, means for imparting to said blowpipe or mold a rotational movement, the one relative to the other, and means for wetting the mold between blowing operations.



11,669. PIPE-ORGAN. ERNEST M. SKINNER, Boston, Mass., assignor of one-half to George S. Hutchings, Cambridge, Mass. Filed Jan. 26, 1898. Serial No. 667,945. Original No. 595,660, dated Dec. 14, 1897.

Claim.—1. In a pipe-organ a series of keys A having each a side recess a^3 combined with spring-contact wires *b* b^2 secured to supporting-blocks *b'* as and for the purpose set forth and described.

2. In a pipe-organ a series of keys A having each a side recess a^3 combined with spring-contacts wires *b* b^2 secured to supporting-blocks *b'*, and wires, having switch-plates *d*, switches d^3 and electromagnets in the circuit substantially as and for the purpose set forth and described.

3. In a pipe-organ action electromagnets having a plurality of independent windings, an independent energizing-circuit for each winding, including a key-contact and an intermediate switch-plate or switch, a return-wire common to all the independent energizing-circuits, and a suitable source of electric energy, substantially as described.

4. In a pipe-organ action, electromagnets having cores which are provided with multiple windings, a common return-wire to which all of said windings are connected, an independent energizing-wire for each winding, a key-contact and an intermediate switch or switch-plate interposed in said wire, and a suitable source of electric energy to the opposite poles of which the common return-wire and the independent energizing-wires are respectively connected, substantially as described.

5. In a pipe-organ action magnets having cable windings composed of two or more insulated strands of wire each in electrical circuit with a single one of the various keys or stops of the organ-action, and so connected that a current through any one of the said strands will energize the magnet, substantially as described.

6. In an organ-action, a magnet having a plurality of windings each in electrical circuit with a single one of the various keys or stops of the organ-action, and so connected that a current through any one of said windings will fully energize the magnet, substantially as described.

7. In an organ-action, an electrical crescendo device, consisting of a movable switch-lever combined with a contact leading to and through a battery or electric generator, and a succession of contacts, each in series with a magnet controlling one of the various stops and couplers of the organ action, substantially as described.

8. In a pipe-organ, in combination, a magnet-box containing an electromagnet, an armature-block above said box, a perforated veneer interposed between said box and block and a movable armature-valve arranged in said perforated veneer substantially as and for the purpose set forth and described.

9. In a pipe-organ in combination a magnet-box containing an electromagnet, an armature-block above said box, a perforated veneer interposed between said box and block and a movable armature having a central valve adapted to close an opening leading to the exit-opening, substantially as and for the purpose set forth and described.

10. In a pipe-organ action in combination a magnet-box containing an electromagnet, a magnet-plate secured to said box and metal circuit-plates arranged between said box and magnet-plate for the purpose of establishing electrical connection between the inside and outside of said box as herein set forth and specified.

11. In a pipe-organ action, the combination with a battery or other generator of electricity, of an electromagnet, a winding *q* for the same, a resistance-coil S" in series with the winding, an intermediate return R" common to said winding and resistance-coil and connected to a return-plate *q''*, a return-circuit for said electromagnet, a pneumatic-diaphragm S' and contact-springs q^3 and *r'*, on the return-plate, whereby the resistance-coil S" in the return-circuit is normally shunted through the intermediate return R", but is thrown in series with the winding *q* while the intermediate retard R" is opened at q^3, *r'* as soon as the pneumatic operates, substantially as described.

12. In an organ-action, the combination with a valve *t*, of a pneumatic diaphragm or bellows T, to control said valve, a magnet-chamber T" containing magnets controlling stops or couplers, and an automatic device to break the return-wire of said magnets simultaneously with the exhaustion of said chamber by said valve *t*, substantially as described.

13. In an organ-action the combination with a pneumatic-diaphragm, U, of an air-passage V, having a small vent or air-passage V" and a pair of electromagnets *u*, *u'*, and armature-valves, serving in turn to exhaust and inflate the air-passage V, substantially as described.

14. In an organ-action a pneumatic-diaphragm U and channels V V' and a pair of electrically-operated armature-valves serving respectively as exhausting and inflating devices for the pneumatic-diaphragm U, in combination with a vent or windway V" serving as a communication between channels V and V' substantially as and for the purpose set forth and described.

15. In an organ-action a pneumatic-diaphragm U and channel V and a pair of electrically-operated armature-valves serving respectively as exhausting and inflating devices for the pneumatic-diaphragm U, and a vent V" combined with the electrical connections V^3 and V^4 and pneumatically-controlled contact-spring W substantially as and for the purpose set forth.

16. In an organ-action the combination with a diaphragm or equivalent pneumatic U and a valve U^2 connected thereto, of an air-passage V controlling said pneumatic, a channel V' controlled by said valve, and a means of communication V", between said passage and channel, substantially as and for the purpose set forth.

17. In an organ-console swing sides having grooves for the reception of the roll or lid, and containing and supporting within themselves the draw-stops or registers and their suitable contact devices substantially as and for the purpose set forth.

18. In an organ-console swing sides and draw-stops or registers and their suitable contact devices carried thereby, substantially as described.

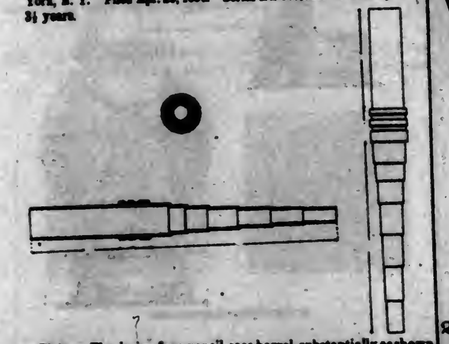
19. In an organ-console swing sides and draw-stops or registers and their suitable contact devices contained and supported within said sides, substantially as described.

20. In an organ-console swing sides, draw-stops or registers and their suitable contacts carried thereby, and a lid, substantially as described.

21. In an organ-console swing sides carrying draw-stops or registers.

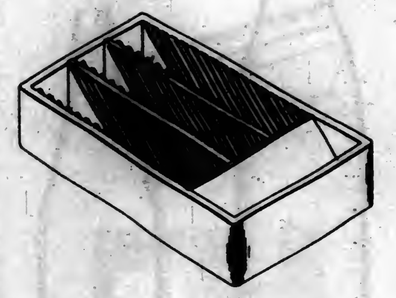
DESIGNS.

28,836. CIGAR. HENRY HEITHAUS, Miamisburg, Ohio. Filed May 2, 1898. Serial No. 679,548. Term of patent 3½ years.



Claim.—The design for a cigar as herein shown and described.

28,837. PIN. WOODBURY MILLIKEN, East Orange, N. J. Filed Mar. 31, 1898. Serial No. 675,997. Term of patent 7 years.



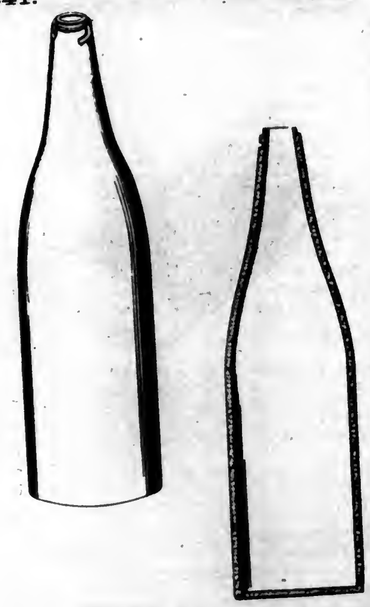
Claim.—The design for a pin herein shown and described.

28,838. PENCIL-CASE BARREL. LE ROY C. FAIRCHILD, New York, N. Y. Filed Apr. 20, 1898. Serial No. 679,246. Term of patent 3½ years.

Claim.—The design for a pencil-case barrel, substantially as shown and described.

28,839. FILE-CASE FOR SALES-BOOKS. EDWIN KIRKWOOD, Minneapolis, Minn. Filed July 3, 1897. Serial No. 643,494. Term of patent 7 years.

Claim.—The design for a file-case for sales-books, substantially as shown and described.

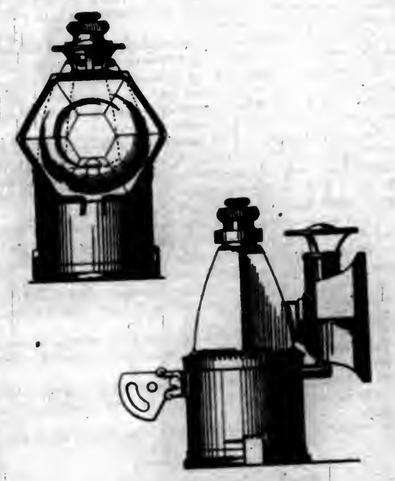


28,840. PLATE. HENRY REMY, Baltimore, Md. Filed May 6, 1898. Serial No. 679,961. Term of patent 3½ years.

Claim.—The design for a plate herein shown and described.

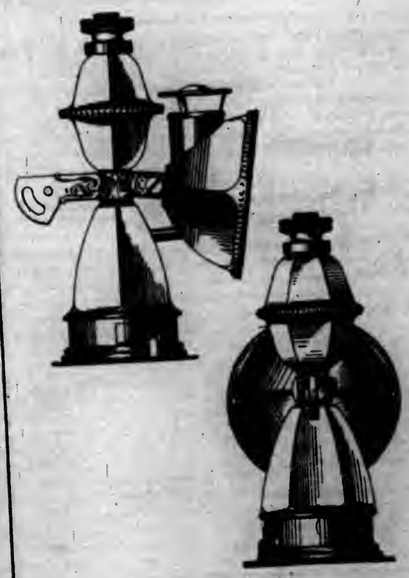
28,841. BOTTLE. PHILIP LIPPENCOTT, Baltimore, Md., assignor to the Monarch Manufacturing Company, same place. Filed Apr. 16, 1898. Serial No. 677,781. Term of patent 7 years.

28,841.



Claim.—The design for a bottle as herein shown and described.

28,842. BOTTLE OR JAR. MARTIN R. GRIFFITH, Manor Station, Pa. Filed Aug. 26, 1897. Serial No. 649,645. Term of patent 14 years.



Claim.—The design for a bottle or jar as herein shown and described.

28,843. LAMP. CHARLES W. IDEN, New York, N. Y., assignor to the Electro Lamp Company, of West Virginia. Filed Mar. 28, 1898. Serial No. 674,944. Term of patent 14 years.

Claim.—The design for a lamp substantially as shown and described.

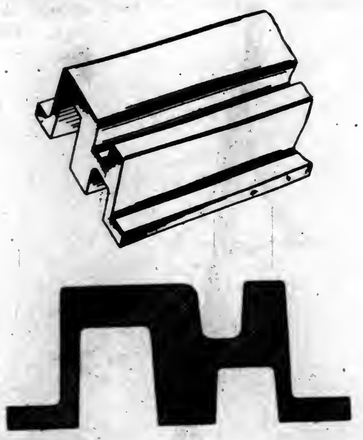
28,844. LAMP. CHARLES W. IDEN, New York, N. Y., assignor to the Electro Lamp Company, of West Virginia. Filed Mar. 28, 1898. Serial No. 674,945. Term of patent 14 years.

Claim.—The design for a lamp, substantially as shown and described.

28,845. CHIMNEY. ANDREW HOWARD, Wilkinsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,103. Term of patent 14 years.

Claim.—The design for a chimney herein shown and described.

28,846. SURFACE ORNAMENTATION OF GLASS. ANTHONY DIXON BROGAN and ANDREW MURRAY MALLOCH, Glasgow, Scotland. Filed May 13, 1898. Serial No. 680,642. Term of patent 14 years.



Claim.—The design for the surface ornamentation of glass substantially as herein shown and described.

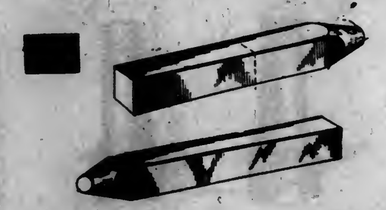
28,847. SHEET OR PLATE GLASS. WILLIAM BUTLER, Red Key, Ind. Filed Feb. 17, 1898. Serial No. 670,713. Term of patent 14 years.

Claim.—The design for sheet and plate glass, substantially as herein shown and described.

28,848. RAILROAD-RAIL. GEORGE B. TAYLOR and HENRY B. HUMPHREYS, Philadelphia, Pa. Filed Apr. 20, 1898. Serial No. 678,311. Term of patent 14 years.

Claim.—The design for a railroad-rail, substantially as illustrated and herein described.

28,849. ANTIRATTLER. FRANK P. JOHNSON, Danville, Pa. Filed Nov. 27, 1897. Serial No. 660,012. Term of patent 14 years.



Claim.—A design for an antirattler for thill-couplings, as herein shown and described.

28,850. ANTIRATTLER PLATE. CHARLES T. REDFIELD, Glen Haven, N. Y. Filed May 12, 1898. Serial No. 680,516. Term of patent 7 years.

Claim.—The design for an antirattling plate as herein shown and described.

28,851. SPIKE-HOLE PLUG. OBIE ASHLEY, New Albany, Pa. Filed May 12, 1898. Serial No. 680,522. Term of patent 3½ years.

Claim.—The design for a spike-hole plug substantially as herein shown and described.

28,852. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,104. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

28,853. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,105. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

28,854. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,106. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

28,855. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,107. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

28,856. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,108. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

28,857. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,109. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

28,858. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,110. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

28,859. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,111. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

28,860. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,112. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

28,861. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,113. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

28,862. BOTTLE. ALBERT C. WILSON, Pittsburg, Pa. Filed Dec. 28, 1897. Serial No. 663,114. Term of patent 14 years.

Claim.—The design for a bottle as herein shown and described.

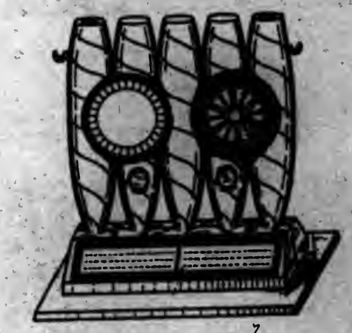
28,852. FURNACE BAR GRATE-SUPPORT. John W. Holabay, Akron, Ohio. Filed May 12, 1898. Serial No. 680,518. Term of patent 7 years.

Claim.—The design for a furnace bar grate-support, substantially as shown and described.

28,853. HORSESHOE-CALK. Thomas J. Gilsenan, Scranton, Pa. Filed Feb. 10, 1897. Serial No. 622,850. Term of patent 14 years.

Claim.—The design for a horseshoe-calk, substantially as shown and described.

28,854. CAP FOR COLLAPSIBLE TUBES. Abram I. Shrimpton, Asbury Park, N. J., assignor to Barrang & Zacharias, same place. Filed Sept. 30, 1897. Serial No. 653,651. Term of patent 7 years.



Claim.—The design for a cap for collapsible tubes, as herein shown and described.

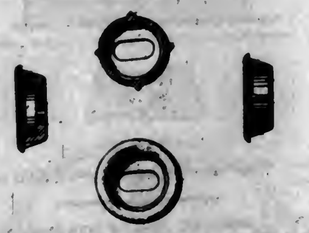
28,855. ADVERTISING-STAND. William H. Updegrave, Johnstown, Pa. Filed Oct. 20, 1897. Serial No. 656,042. Term of patent 7 years.

Claim.—The design for an advertising-stand, substantially as herein shown and described.

28,856. CASING OR FRAME FOR VENDING-MACHINES. Edward Rosenberg, Cincinnati, Ohio. Filed April 15, 1898. Serial No. 677,702. Term of patent 7 years.

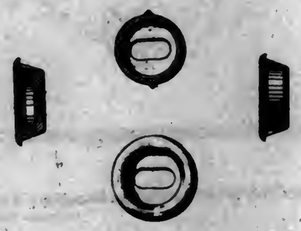
Claim.—The design for a casing or frame for vending-machines substantially as shown and described.

28,857. WINDOW-STOP ADJUSTER. Clarence A. Taplin, Putnamville, Conn., assignor to the Taplin Manufacturing Company, same place. Filed May 13, 1898. Serial No. 681,081. Term of patent 14 years.



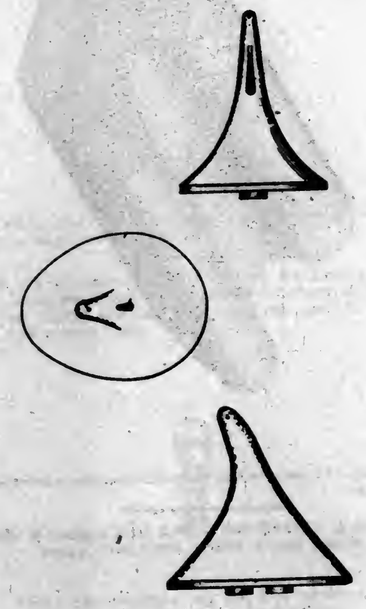
Claim.—The design for a window-stop adjuster herein shown and described.

28,858. BRACKET FOR CURTAIN-POLES AND SHADE-ROLLERS. Albert C. Smith, Boulder, Colo. Filed May 14, 1898. Serial No. 680,746. Term of patent 14 years.



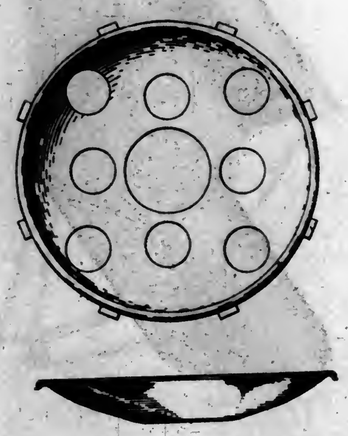
Claim.—The design for a curtain-pole and shade-roller bracket, substantially as herein shown and described.

28,859. BEAD-ENGAGING THIMBLE. Hobart B. Ives, New Haven, Conn. Filed Dec. 31, 1897. Serial No. 665,341. Term of patent 14 years.



Claim.—The design for bead-engaging thimble for adjustable window-bead fasteners, as herein shown and described.

28,860. BEAD-ENGAGING THIMBLE. Hobart B. Ives, New Haven, Conn. Filed Dec. 31, 1897. Serial No. 665,342. Term of patent 14 years.



Claim.—The design for a bead-engaging thimble for adjustable window-bead fasteners, as herein shown and described.

28,861. SYRINGE-NOZZLE. James T. Westerfield, Boston, Mass. Filed Feb. 14, 1898. Serial No. 670,333. Term of patent 14 years.

Claim.—The design for a syringe-nozzle, as herein shown and described.

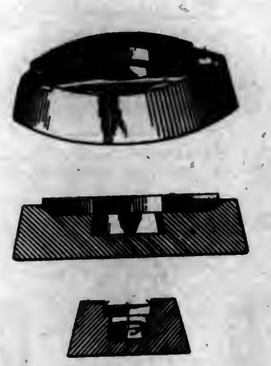
28,862. SPITTOON-COVER. Karl Riehle, Sandusky, Ohio. Filed Jan. 26, 1898. Serial No. 668,078. Term of patent 7 years.

Claim.—The design for a spittoon-cover, as herein shown and described.

28,863. CHANNEL-IRON. JAMES H. BAKER, Allegheny, Pa. Filed Oct. 30, 1897. Serial No. 656,967. Term of patent 14 years.

Claim.—The design for a channel-iron, substantially as shown and described.

28,864. CHANNEL-IRON. JAMES H. BAKER, Allegheny, Pa. Filed Oct. 30, 1897. Serial No. 656,968. Term of patent 14 years.

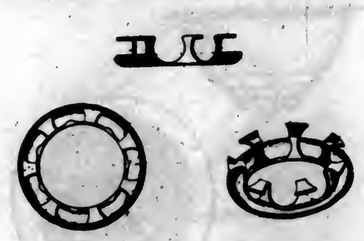


Claim.—The design for a channel-iron for railroad-coupling substantially as shown and described.

28,865. ANGLE-IRON. JAMES H. BAKER, Allegheny, Pa. Filed Oct. 30, 1897. Serial No. 656,969. Term of patent 14 years.

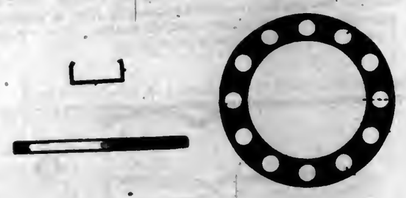
Claim.—The design for an angle-iron, substantially as shown and described.

28,866. SAD-IRON. JAMES F. BLISS, Newark, N. J. Filed May 17, 1898. Serial No. 680,991. Term of patent 7 years.



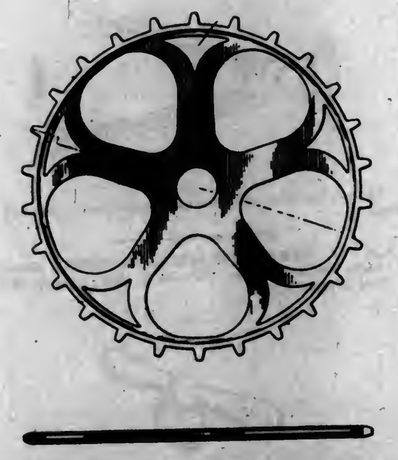
Claim.—The design for an sad-iron: substantially as shown and described.

28,867. LOCK-CLASP. HARRY G. PRICE, Philadelphia, Pa. Filed May 13, 1898. Serial No. 680,641. Term of patent 14 years.



Claim.—The design for a lock-clasp, substantially as shown and described.

28,868. BALL-RETAINER. HENRY B. KNUPH, Lancaster, Pa., assignor of one-half to John Hertzler, same place. Filed May 17, 1898. Serial No. 680,989. Term of patent 14 years.



Claim.—The design for a ball-retainer substantially as shown and described.

28,869. CAGE FOR BALL-BEARINGS. ALBERT PERKINS, Chicopee, Mass. Filed May 10, 1898. Serial No. 680,294. Term of patent 7 years.

Claim.—The design for a cage for ball-bearings, substantially as shown and described.

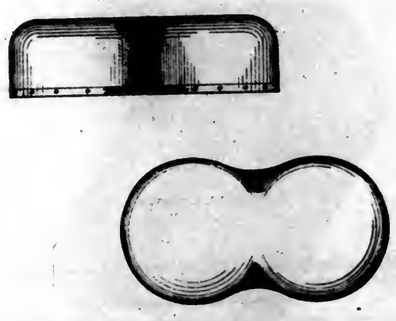
28,870. SPROCKET-WHEEL. LEE STURGES, Elmhurst, Ill. Filed Apr. 20, 1898. Serial No. 679,401. Term of patent 3½ years.

Claim.—The design for a sprocket wheel or gear, substantially as shown and described.

28,871. BICYCLE WRENCH AND SCRAPER. LOUIS HOLMES, Chicago, Ill. Filed Apr. 4, 1898. Serial No. 676,473. Term of patent 3½ years.

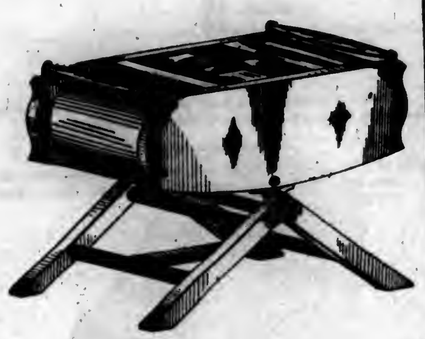
Claim.—The design for a bicycle wrench and scraper substantially as herein shown and described.

28,872. HEAD AND SHANK MEMBER FOR BICYCLE-PUMPS. JOHN H. GOSS, Waterbury, Conn., assignor to The Scovill Manufacturing Company, same place. Filed Mar. 7, 1898. Serial No. 673,016. Term of patent 7 years.

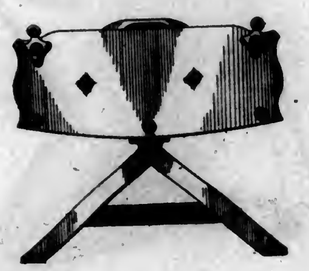


Claim.—The design for a head and shank member of a swivel connection for bicycle-pumps as shown and described.

28,873. BICYCLE-FRAME. CHARLES HERBERT OGDEPAUGH, Rochester, N. Y. Filed Apr. 20, 1898. Serial No. 679,245. Term of patent 14 years.

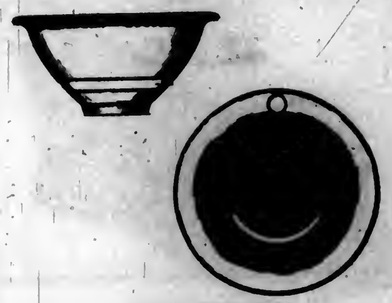


Claim.—The design for a bicycle-frame, as herein shown and described.



28,874. BICYCLE-SADDLE. LE ROY M. HILBURN, New Haven, Conn. Filed May 2, 1898. Serial No. 679,545. Term of patent 14 years.

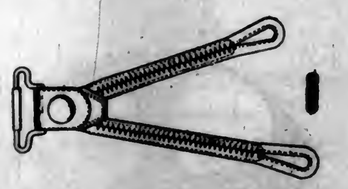
Claim.—The design for a bicycle-saddle as herein shown and described.



28,875. CHURN-BODY AND SUPPORT. THOMAS H. BUFFY, Manchester, Va. Filed Oct. 30, 1896. Serial No. 610,638. Term of patent 7 years.

Claim.—The design for a churn-body and support, substantially as shown and described.

28,876. EGG-SEPARATOR. BERNARD F. MAGY, Smithdale, Mass. Filed Sept. 30, 1897. Serial No. 653,303. Term of patent 7 years.

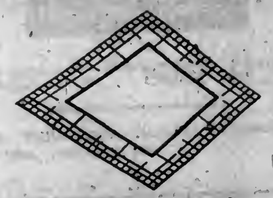


Claim.—The design for an egg-separator substantially as herein shown and described.

28,877. SUSPENSION-HOLDER FOR UMBRELLAS. JULIUS H. SCHMIDT, Bayonne, N. J., assignor of one-half to Peter H. Schaffer, same place. Filed Apr. 22, 1898. Serial No. 678,198. Term of patent 7 years.

Claim.—The design for a suspension-holder for umbrellas, substantially as shown and set forth.

28,878. SUSPENDER-END. FRANK P. KNOWER, New York, N. Y. Filed Oct. 12, 1897. Serial No. 654,993. Term of patent 7 years.



Claim.—The design for a suspender-end as herein shown and described.

28,879. TRIMMING FOR GARMENT-SUPPORTERS. GEORGE E. ADAMS, New Britain, Conn. Filed Jan. 19, 1898. Serial No. 667,174. Term of patent 7 years.

Claim.—The design for a metal trimming for a garment-supporter, substantially as herein shown and described.

28,880. PATTERN-PLATE FOR GARMENTS. FREDERICK HAHNE, New York, N. Y. Filed May 12, 1898. Serial No. 680,510. Term of patent 7 years.

Claim.—The design for a pattern-plate for garments, substantially as herein shown and described.

28,881. BRAID. MEYER W. SELIGSON, New York, N. Y. Filed May 11, 1898. Serial No. 680,417. Term of patent 3½ years.

Claim.—The design for a braid as herein shown and described.

28,882. CARPET. ANDREW C. PROUDFIT, Philadelphia, Pa., assignor to John Dunlop & Son, same place. Filed Apr. 21, 1898. Serial No. 678,300. Term of patent 3½ years.

Claim.—The design for a carpet substantially as herein shown and described.

TRADE-MARKS

REGISTERED JUNE 14, 1898.

81,678. CORSETS. BELLE J. MONTGOMERY, Toledo, Ohio. Filed Apr. 23, 1898.

VENO

Essential feature.—The word "VENO." Used since March 1, 1898.

81,679. CERTAIN NAMED RUBBER GOODS. THE DIAMOND RUBBER COMPANY, Akron, Ohio. Filed Mar. 24, 1898.

TITAN

Essential feature.—The word "TITAN." Used since January 1, 1898.

81,680. EFFERVESCENT GRANULES FOR BEVERAGES AND MEDICINAL PURPOSES. ARMSTRONG MANUFACTURING COMPANY, Berwick, Me., and Boston, Mass. Filed May 5, 1898.

BOAC

Essential feature.—The word "BOAC." Used since April 1, 1898.

81,681. DENTIFRICES. HALL & RUCKEL, New York, N. Y. Filed May 5, 1898.

SOZODONT

Essential feature.—The word "SOZODONT." Used since October, 1863.

81,682. HAIR-TONIC. MÜLHENS & KROPFF, New York, N. Y. Filed Mar. 4, 1898.

Essential feature.—The representation of a Medusa's head. Used since January 7, 1898.

81,688. OINTMENT. MICHAEL ARTHUR WHEELER, Troy, N. Y. Filed Apr. 25, 1898.

PIXINE

Essential feature.—The word "PIXINE." Used since April 19, 1898.

81,684. COMBUSTIBLE POWDERS FOR FLASH-LIGHTS. GEORGE P. PARTON, Scranton, Pa. Filed Mar. 26, 1898.

ACTINO

Essential feature.—The word "ACTINO." Used since January, 1897.

81,685. DISINFECTING AND ANTISEPTIC PREPARATIONS. FRIEDR. REISSER, New York, N. Y. Filed Mar. 31, 1898.

HYDRO=SOL

Essential feature.—The compound word "HYDRO-SOL." Used since August 1, 1896.

81,686. INDIGO BLUING. ADAM PFROMM, Philadelphia, Pa. Filed Apr. 5, 1898.

BARLOW'S

Essential feature.—The word "BARLOW'S." Used since October 1, 1853.

81,687. PORTLAND CEMENT. THE FRANK H. MORSE COMPANY, Newark, N. J., and New York, N. Y. Filed Apr. 7, 1898.

PATRIOT

Essential feature.—The word "PATRIOT." Used since April 1, 1898.

81,688. DIETETIC ALBUMINOUS PREPARATIONS. EBNER & GIE, Berlin, Germany. Filed Feb. 26, 1898.

SANATOGEN

Essential feature.—The word "SANATOGEN." Used since October 26, 1897.

81,689. CEREAL FOOD FOR HUMAN CONSUMPTION. POSTUM CEREAL COMPANY, Limited, Battle Creek, Mich. Filed Jan. 31, 1898.

[redacted]

Essential feature.—The compound word "GRAPE-NUTS." Used since December 1, 1897.

81,690. WHEAT-FLOUR. CONSOLIDATED MILLING COMPANY, Minneapolis, Minn. Filed Apr. 19, 1898.

Essential feature.—The representation of a child seated, wearing a large hat, and cutting a slice from a loaf of bread. Used since August 1, 1896.

81,691. OLIVE-OIL. SEWELL & PETER, Limited, Philadelphia, Pa. Filed Mar. 4, 1898.

BONDURANT FRÈRES

Essential feature.—The words "BONDURANT FRÈRES." Used since June 12, 1893.

81,692. ROASTED AND GROUND COFFEE. THE RETREPPERS COFFEE COMPANY OF BALTIMORE CITY, Baltimore, Md. Filed Mar. 26, 1898.

Essential feature.—A picture of a plantation scene in an oval with negroes gathering and carrying coffee to a shed, above which a palm-tree spreads its leaves, and the words "PLANTATION GROUND COFFEE." Used since November, 1874.

81,693. SUGAR-SYRUP. J. D. HAGG & CO., New York, N. Y. Filed Apr. 30, 1898.

APOLLO

Essential feature.—The word "APOLLO." Used since October 5, 1896.

81,694. FLUID EXTRACT OF MALT. ALLEN & HANBURYS, Limited, London, England. Filed Feb. 15, 1898.

BYNIN

Essential feature.—The word "BYNIN." Used since November, 1884.

81,695. WHISKY. FRANK H. RINKER & CO., Boston, Mass. Filed May 2, 1898.

GOV. RUSSELL BLENDS

Essential feature.—The words "GOV. RUSSELL BLENDS." Used since April 13, 1898.

81,696. WHISKY. WISE & MEYER, New York, N. Y. Filed Mar. 6, 1898.

INGLESIDE

Essential feature.—The word "INGLESIDE" and a monogram formed by the letters and character "W & M" interwoven. Used since December 1, 1897.

81,697. CIGARS, TOBACCO, AND CIGARETTES. WILLIAM W. ARNOLD, Denver, Colo. Filed May 2, 1898.

SCENIC LINE

Essential feature.—The words "SCENIC LINE." Used since January 1, 1898.

81,698. PHOTOGRAPHIC CAMERAS. WESTERN CAMERA MANUFACTURING COMPANY, Chicago, Ill., and New York, N. Y. Filed Feb. 26, 1898.

Cyclone

Essential feature.—The word "CYCLONE." Used since February 1, 1897.

81,699. CERTAIN NAMED APPARATUS AND SUPPLIES. LA SOCIÉTÉ CHIMIQUE DES USINES DU RHÔNE, Assignment Gillard, P. Monnet et Cartier, Lyons, France. Filed Apr. 26, 1898.

TRILLAT

Essential feature.—The word "TRILLAT." Used since May 16, 1896.

81,700. AXES, SAWS, AND HATCHETS. DUNBAR, CARRIGAN & HAYDEN COMPANY, San Francisco, Cal. Filed Mar. 18, 1898.

CLEAN CUT

Essential feature.—The words "CLEAN CUT." Used since April 9, 1884.

81,701. TYPE-WRITING MACHINES AND NAMED SUPPLIES. ROBERT G. HOPKINS, Boston, Mass. Filed Mar. 23, 1898.

Essential feature.—The autograph signature of the registrant "ROBERT G. HOPKINS." Used since June, 1896.

81,702. CARPET-SWEEPERS. BISSELL CARPET SWEEPER COMPANY, Grand Rapids, Mich. Filed Mar. 12, 1898.

AMERICAN QUEEN

Essential feature.—The words "AMERICAN QUEEN." Used since September 15, 1897.

81,708. SEWING-MACHINES. THE HAVEN SEWING MACHINE COMPANY, Dayton, Ohio. Filed Apr. 4, 1898.

CRESCENT

Essential feature.—The word "CRESCENT." Used since November 16, 1897.

THE NORRIS PETERS CO.

DECISIONS

OF THE

COMMISSIONER OF PATENTS

AND OF

UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

EX PARTE WHITNEY.

Decided May 13, 1898.

1. INTERFERENCE—RESTRAINING AN EXAMINER FROM DECLARING AN INTERFERENCE—JURISDICTION OF THE COMMISSIONER.

The Commissioner is warranted in taking jurisdiction of and granting a petition to restrain an Examiner from declaring an interference when it clearly appear that the Examiner's intended action is contrary to the practice of the Office as indicated by the decisions of the Commissioner. (Citing *ex parte Baker*, 64 MS. Dec., 71.)

2. SAME—PATENT AND APPLICATION—PROTECTING RIGHTS OF PATENTEE.

The Office is not bound to declare an interference between a patent and an application in order to give the patentee the opportunity of contesting the grant of a patent to the applicant because in its judgment the patentee's rights would be infringed or abridged by granting a patent on a pending application.

3. SAME—MAKING THE INTERFERENCE ISSUE.

The Examiner should not make an issue for the purpose of bringing about an interference. The applicants should make the issues by their claims. If an Examiner desires the issue to be different, he should arrive at that result by requiring the claims to be amended by the applicants. (Citing *Hammond* v. *Hart*, 83 O. G., 743.)

4. SAME—SAME—PATENTEE AND APPLICANT.

The Office has no control over a patentee to require him to amend his claims. Unless an applicant make substantially the same claim as the patentee no interference can be declared.

5. SAME—SAME—SAME—CONSTRUING CLAIMS OF THE PATENT.

For the purpose of declaring an interference the claims of a patent must be taken as they read. The Office has no authority to say that any of the limitations contained in the claims of a patent are immaterial and unessential. Presumably the patentee did not put any unnecessary limitations in his claims.

6. PRACTICE—OPINIONS OF AN EXAMINER—FOLLOWING DECISIONS OF THE COMMISSIONER.

Whatever may be the individual opinions of an Examiner the orderly course of business requires that the decisions of the Commissioner should be followed.

ON petition.

COVERINGS FOR DRIVING-CHAINS FOR USE WITH BICYCLES AND MOTOR-CARRIAGES.

Application of George E. Whitney filed January 20, 1897, No. 619,895.

Messrs. Crosby & Gregory for the applicant.

DUELL, *Commissioner:*

The applicant seeks by petition to have the Examiner restrained from the declaration of what is said to be an absolutely improper interference.

The facts show that the applicant was rejected on a patent issued after his application was filed. The patent as a reference was overcome by affidavit made under and in accordance with Rule 75, whereupon the Examiner indicated his intention of declaring an interference between the patent and the application. The Commissioner, under the facts stated, will be warranted in granting the petition if it clearly appear that the Examiner's intended action is contrary to the practice of the Office as indicated by the decisions of the Commissioner; otherwise the petition should be refused.

Turning to the Examiner's statement, he urges that he "can find no precedent for such petition." The Examiner's attention is called to *ex parte Baker*, (64 MS. Dec., 71,) which it is thought will satisfy him on this point. The Examiner further states that—

> the Office is bound to declare the interference, if in its judgment the patentee's rights would be infringed or abridged by the granting of a patent on a pending application, in order to give him the opportunity of contesting this grant.

Interferences are not delared for any such purpose. The Examiner's attention is called to *Hammond* v. *Hart*, (83 O. G., 743,) where it is expressly stated that—

> an interference can only be instituted for the purpose of determining the question of priority of invention between two or more parties *claiming* substantially the same patentable invention.

If the applicant is *claiming* substantially the same patentable invention *claimed* by the patentee, then the Examiner is justified in declaring an interference; otherwise not.

This leads us to the main question raised by the petition, whether or not an interference is warranted by the practice and the law as laid down by the statutes and the decisions of the Commissioner relating to interferences. In order to bring about the interference, the Examiner proceeds to make an issue for the purpose. This practice was condemned and the proper course indicated in *Hammond* v. *Hart*, *supra*, in the following terms:

> In other words, the Examiner has made two new issues, neither of which is an allowed claim made by either party. I believe this to be bad practice. The applicants should make the issues by their claims. If an Examiner for any reason desires the issues to be different, he should arrive at that result by requiring the claims to be amended by the applicants.

In the present case one of the parties to the proposed interference is a patentee, and the Office has no control over him. Therefore the Examiner cannot take the course above indicated. Unless the applicant is making substantially the same claim or claims as the patentee has made no interference can be declared. The Examiner admits that the claims of applicant could not be read literally upon the construction shown by the patentee, and, *vice versa*, that the claims of the patentee would not read literally upon applicant's construction; but

he says that the limitations in the claims are entirely immaterial and unessential ones. Unfortunately for patentees the courts have too often held that limitations incorporated into the claims of their patents cannot be treated as immaterial and unessential. I fail to see what authority the Patent Office has, after it has issued a patent, to say that any of the limitations contained in the claims are immaterial and unessential. For the purpose of declaring an interference the claims of a patent must be taken as they read. Presumably the patentee did not put any unnecessary limitations in his claims. Whether or not the subject-matter of the proposed issue might have been claimed by the patentee or can be claimed by the applicant is not the question under discussion. The patentee did not claim it and now could claim it, if at all, only by reissue. No interference in fact exists between the claims of the patentee and the applicant, and therefore it would be manifestly improper for the Examiner to declare one under the decisions which must control his action. (*Reed* v. *Landman*, 55 O. G., 1275; *Hammond* v. *Hart*, 83 O. G., 743.)

The Examiner in his answer makes the following statement, which I cannot pass unnoticed:

> It would be manifestly unfair to issue applicant's patent on any such *ex parte* proceedings as the one now proposed if there is even a reasonable doubt as to the existence of an interference between the application and the reference, which was valid until overcome by affidavit.
